Synovial osteochondromatosis can occur anywhere synovium is found, yet it is rarely found outside of large joint spaces. Our search of English language literature found only 11 cases of spinal synovial osteochondromatosis. Of these, seven were paravertebral, resulting in nerve root compression and radiculopathy. One lumbar spinal canal mass compressed the cauda equina, and one spinal canal mass at the C1-C2 level was not compressive. Two cases of spinal cord compression by synovial osteochondromatosis have been described in the thoracic spine and cervical spine. Our case is only the second described instance of cervical spinal cord compression from synovial osteochondromatosis.

Correlation of Vasospasm on CTA and CTP Perfusion Deficits

Vora, A. P.
Weill Cornell
New York, NY.

Purpose

Following aneurysmal subarachnoid hemorrhage (a-SAH), vasospasm and delayed cerebral ischemia (DCI) are major contributors to poor clinical outcomes. Vasospasm, defined as arterial narrowing on angiographic imaging studies, is thought to lead to perfusion deficits in the distal vascular territory. Perfusion deficits on CT perfusion (CTP) have been shown to be related to DCI. It is questioned whether angiographic vasospasm is related directly to perfusion deficits. The purpose of this study was to correlate arterial vasospasm on CT angiography (CTA) and perfusion deficits on CTP.

Materials & Methods

A retrospective study of consecutive a-SAH patients admitted from January 2005 to December 2011 was performed. Inclusion criteria were a-SAH patients who received concurrent CTA and CTP following aneurysm rupture. CT angiographies were reviewed by two independent neuroradiologists, blinded to all clinical and imaging data, to determine the presence or absence of vasospasm and its degree defined as mild (stenosis 75%). For cases of disagreement, a third neuroradiologist reviewed the CTA as a tie-breaker. CT perfusions were reviewed by two independent neuroradiologists, blinded to all clinical and imaging data, to determine the qualitative presence or absence of a perfusion deficit. Perfusion deficits were defined as focal areas of reduced cerebral blood flow and/or elevated mean transit time. Quantitative CTP analysis was performed by region-of-interest (ROI) placement in each vascular territory using a

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

standardized method. Statistical analysis included agreement rates measured by Kappa statistic and McNemar chi-square test. The mean CTP values were compared using analysis of variance.
Results
A total of 50 patients with concurrent CTA and CTP were studied with 298 vascular territories examined. The overall agreement rate is considered as none-slight (Kappa = 0.055). Seventy-three percent (218/298) of vascular territories did not demonstrate CTP deficits. Of these territories, 85% (185/218) had none/mild vasospasm and 15% (33/218) had moderate/severe vasospasm on concurrent CTA. Twenty-seven percent (80/298) of territories had CTP deficits, 80% (64/80) had none/mild vasospasm and 20% (16/80) had moderate/severe vasospasm on concurrent CTA. The McNemar chi-square test reveals a statistically significant p-value (0.002319) indicating the disagreement is not spread evenly in these two groups. Table 1 demonstrates the mean quantitative CTP values for patients with none/mild vasospasm compared to moderate/severe vasospasm. There was no statistically significant difference between these CTP parameters.

Mean for the quantitative CTP parameters

CTP parameter	None/Mild vasospasm n=249	Moderate/Severe vasospasm n=49
CBF (mL/100 gm/min)	38.5	39.0
CBV (mL/100 gm)	2.06	2.28
MTT (sec)	5.54	5.61

Conclusion
Our results show no statistically significant correlation between the degree of vasospasm on CTA and qualitative or quantitative CTP deficits in the corresponding vascular territory. Disagreement between the CTA and CTP was more pronounced when a CTP deficit was present indicating that the CTP deficit may be due to causes other than vasospasm on CTA. However, when there was no CTP deficit present, there was improved agreement between CTA and CTP.

Cerebral Vascular Lesions: Diagnostic Value of 4D Dynamic Contrast-Enhanced MR Angiography Compared with 3D Time-of-Flight MR Angiography

Cheng, Y.·Chen, H.·Wu, C.·Chen, W.·Chen, C.
Taichung Veterans General Hospital, Taiwan
Taichung, TAIWAN.

Purpose
For early diagnosis and evaluation of cerebral vascular lesions such as arteriovenous malformation (AVM) and arteriovenous fistula (AVF), digital subtraction angiography (DSA) has remained a gold standard diagnostic method. The aim of this study was to analyze the value of different magnetic resonance angiographic images, 4D dynamic contrast-enhanced MRA (D MRA) and time-of-flight magnetic resonance angiography (TOF MRA), to identify their effect on evaluating cerebral vascular lesions.
Materials & Methods
A total of 47 patients with AVM or AVF at their initial evaluation or for followup after treatment were included in this study. Dynamic MRA and TOF examinations were performed simultaneously with conventional angiography as standard references. Two experienced neuroradiologists reviewed the images to compare the diagnosis accuracy, arterial feeder and venous drainage between these two MRA methods. Interobserver and intermodality agreement was assessed by Wilcoxsin Rank sum test.
Results
Almost all vascular lesions (86.7%) were diagnosed correctly using D MRA. However, the MIP TOF MRA only detected 62.2% of the lesions. There is a statistically significant difference regarding the lesion diagnostic accuracy ($p = 0.012$), arterial feeder ($p = 0.01$) and venous drainage identification ($p = 0.000$) between D MRA and TOF MRA. Dynamic MRA is superior to MIP TOF MRA for lesion assessment.
Conclusion
Dynamic MRA proved to be a reliable screening modality and follow-up method for cerebral vascular lesions with higher accuracy and consistency with DSA as compared to TOF MRA.

KEYWORDS: 4D MRA, AVM, TOF MRA

Migraine with Visual Aura Due to Occipital Arteriovenous Malformation: Multimodal Imaging Investigation in a Case Series and Review of the Literature

Piccardi, B.[1,2]·La Piana, R.[1]·Klein, D.[1]·Mok, K.[1]·Chen, J.[1]·del Pilar Cortes, M.[1]·Tampieri, D.[1]
[1]Montreal Neurological Institute and Hospital, Montreal, QC, CANADA, [2]University of Florence, Florence, ITALY.

Purpose
Migraine with visual aura (MwVA) is a common presentation for occipital arteriovenous malformation (AVM) with a prevalence ranging between 5% and 28%. This phenomenon seems to be correlated with a state of neuronal hyperexcitability and increases the susceptibility to develop cortical spreading depression, the electrophysiologic correlate of the visual aura. We present a case series of five patients with MwVA attributed to occipital AVM according to the International Classification of Headache Disorders 2nd Edition (ICHD-II). These patients were part of a larger series of 29 cases with AVM referred to our center from 2008 to 2012 for unruptured AVM. Our results emphasize the importance of using a comprehensive protocol that integrates the clinical data with the functional and hemodynamic studies in patients with AVM and MwVA.
Materials & Methods
A comprehensive protocol integrating neurologic examination, ophthalmologic evaluation and neuroimaging was performed. A battery of functional magnetic resonance imaging (fMRI) tasks was administered to all five patients to identify brain regions activated during the performance of visual, motor, sensory and language tasks.
Results
In our series of subjects with AVM, headache was the presenting symptom in 34% (10/29). In this cohort, MwVA always was associated with an occipital localization of the AVM (5/29; 17.2%). In all five patients, the headache was ipsilateral to the lesion while the visual aura was localized in the contralateral visual hemifield. The visual aura was typical in three of them (lasting less than one hour, preceding the headache). In two patients the visual symptoms were often unrelated to headache, triggered by bright light and/or, black and white alternating pattern and lasting more than one hour. In two cases symptoms of visual dysperception other than visual aura were reported. The ophthalmologic examination was normal in all five patients: no evidence of visual field deficit or reduced visual acuity. Of these five patients, only one underwent endovascular treatment. In all patients, the pattern of activation on the fMRI differed from what is observed in healthy controls and showed a more diffuse and complex pattern. In addition, on visual functional imaging tasks, we observed that, despite a normal neurophthalmologic exam, the occipital region affected by the AVM showed a reduction in activation as compared to the unaffected hemisphere. Most interestingly, when stimuli were presented to each visual field, there was an absence of activity in the affected region.
Conclusion
Our study highlights the importance of integrating the clinical information with functional neuroimaging findings in the evaluation of patients with occipital AVM. Although the results are still preliminary, functional imaging data showed unexpected asymmetrical activation in the affected visual cortex despite normal neurophthalmologic exam. These results may be correlated with the important and somewhat unusual visual aura presented by these patients. The combined use of multiple imaging modalities may contribute to a better understanding of this phenomenon and may provide useful information to guide the treatment choice.

Differentiation between Jugular Venous Reflux and Cavernous Dural Arteriovenous Fistula on Routine Brain MR Imaging and MR Angiography

Lee, D.[1]·Kim, E.[2]
[1]Seoul Medical Center, Seoul, KOREA, REPUBLIC OF, [2]Seoul National University Bundang Hospital, Gyeonggi-do, KOREA, REPUBLIC OF.

Purpose
Both jugular venous reflux (JVR) and DAVF manifest as unusual venous signals in the cavernous sinus and its vicinity on TOF MRA. We investigated brain MR imaging and MRA findings that might distinguish JVR from cavernous DAVF.
Materials & Methods
Forty-one patients with JVR and 26 with cavernous DAVF underwent MR imaging and MRA. We assessed the following findings: sidedness and location of unusual venous signals on intracranial TOF MRA; signal intensity of the proximal jugular vein on T2WI; early opacification of the cavernous sinus in the arterial phase of CE MRA; sidedness of jugular venous drainage in the arteriovenous phase of CE MRA; retrograde jugular venous flow on neck TOF MRA.
Results
Unusual venous signals were seen on the left side in 73% of the JVR and 58% of the DAVF patients; involvement of the cavernous sinus was found in 12% of the JVR and 100% of the DAVF patients. Increased signal intensity in the ipsilateral jugular vein on T2WI was found in 73% of the JVR and 4% of the DAVF patients. Early opacification of the cavernous sinus in the arterial phase of CE MRA, ipsilateral jugular venous drainage in the arteriovenous phase of CE MRA, and ipsilateral retrograde jugular venous flow on neck TOF MRA were found in 0%, 0%, and 63%, respectively, of the JVR patients and in 100%, 100%, and

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

0%, respectively, of the cavernous DAVF patients.
Conclusion
Jugular venous reflux and DAVF are associated with different findings from MR imaging and MRA. The CE MRA findings are the most useful for distinguishing between JVR and cavernous DAVF.

Diffusion-Weighted Imaging Cortico-Subcortical Spread Reflects Cognitive-Motor Deterioration in Four Creutzfeldt Jakob Disease Cases

Vitali, P.[1]·Caverzasi, E.[2]·Alvisi, E.[1]·Pan, M.[1]·Bini, P.[1]·Costa, A.[1]·Ceroni, M.[1]·Pingue, V.[3]·Geschwind, M.[2]·Bastianello, S.[1]
[1]IRCCS Neurological Institute Mondino, Pavia, ITALY, [2]University of California San Francisco, San Francisco, CA, [3]IRCCS Institute Maugeri, Pavia, ITALY.

Purpose
In Creutzfeldt-Jackob disease (CJD), diffusion-weighted imaging (DWI) MR hyperintensities are highly sensitive and specific to the cortical and subcortical involvement. Because of the rapidly fatal cognitive and motor deterioration, the pattern of DWI hyperintensities spread during the disease progression has been poorly described. In the present study, four patients with rapidly progressive dementia and subsequently path-proven sCJD were longitudinally scanned (at last three times) during the disease course.
Materials & Methods
Four sCJD patients (three females, 71-77 years old) were scanned in three institutions (Mondino, Maugeri, UCSF) by 1.5T MRI scanners, always including DWI (b = 0, 1000) sequences. In all four cases, clinical and MRI criteria at the presentation were suggestive for sCJD, subsequently pathologically proven at autopsy. In all four cases, behavioral and cognitive signs preceded motor signs, with late myoclonus occurrence. Because the gray matter hyperintensities typically are more evident at the DWI than at FLAIR images, only DWI and ADC maps are presented here, to show the cortico-subcortical spreading of abnormalities with diffusion restriction.
Results
In all four CJD cases presented here, longitudinal scans showed spread of DWI hyperintensities in the cortex ("cortical ribboning", typically sparing precentral gyrus) and subsequent subcortical involvement, with typical antero-posterior gradient in the striatum.

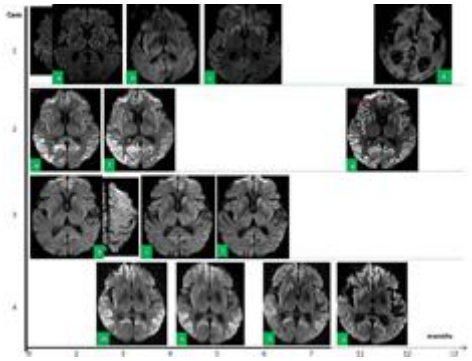

Figure1: Longitudinal DWI. CR = cortical ribboning, SH = striatum hyperintensity. Case 1: (a) right CR; (b) + right SH; (c) bilateral CR/SH; (d) hyperintensities disappearance, Case 2: (e) bilateral CR; (f) + right CR; (g) bilateral CR/SH, Case 3: (h) left CR; (i) + left SH; (l) bilateral CR/SH, and Case 4: (m) bilateral CR (n-o-p) + increasing bilateral SH
Conclusion
Although in cross-sectional studies the pattern of cortico-subcortical involvement varies considerably among different sCJD cases, this longitudinal study shows that the early cortical involvement with subsequent subcortical (striatum) involvement may be the more typical pattern of progression. This is in accordance with the finding that cognitive and behavioral signs typically precede motor signs.

Are Initial Brain Abnormalities in Neurologic Form of Wilson's Disease Compatible with Toxic Myelinolysis?

Kozic, D.[1]·Petrović, I.[2]·Kostic, V. S.[2]
[1]University of Novi Sad School of Medicine, Novi Sad, SERBIA, [2]Institute of Neurology, Belgrade, SERBIA.

Purpose
The purpose of the study was to estimate the nature of the brain lesions in Wilson's disease (WD), that usually in radiologic practice are interpreted as gliosis, spongy degeneration and necrosis. We evaluated the resolution of brain lesions in patients with WD during the long-term chelating therapy by magnetic resonance imaging (MRI) and a possible significance of the time latency from the initial symptoms of the disease to the introduction of such therapy.
Materials & Methods
Initial brain MRI was performed in 37 patients with neurologic presentation of WD. Fourteen patients were reexamined with MRI during the followup of 5.7±1.3 years. Pseudoparkinsonian, cerebellar and dystonic symptoms were evident in 45%, 70% and 35% of patients, respectively.
Results
Putamen affected 78% of patients, but in 100% of those with dystonia. Correlation between putaminal affection

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

and dystonic presentation was statistically significant (p = 0.035). Complete resolution of putaminal lesions was observed in 60% of patients in whom initiation of decoppering treatment started less than two years after initial symptoms and in none of the patients with late diagnosis and treatment initiation (two to five years after symptoms onset), p = 0.024. There was a significant difference between these two groups regarding complete resolution of brain stem lesions (p = 0.005). Complete resolution of midbrain, pontine base and pontine periaqueductal zone lesions was observed in 66%, 100% and 100% of patients in whom initiation of decoppering treatment started less than two years after initial symptoms and in 20%, 20% and 25% of the patients with late diagnosis and treatment initiation, respectively.
Conclusion
The likelihood of complete resolution of brain stem and putaminal lesions in WD appears to be significantly higher if adequate treatment is initiated earlier in the course of the disease. If the correct diagnosis and adequate treatment have not been established within the period shorter than two years from initial symptoms, permanent clinical impairment associated with irreversible lesions within the brain parenchyma could be expected. Since in 100% of patients initial examination revealed frank symmetry of the lesions and that the majority of them were almost completely reversible if marked latency of adequate treatment had not existed, reversible myelinolysis associated with copper toxicity might have been the initial morphologic process. If untreated on time, consequent transformation into gliosis, necrosis and cystic degeneration seemed to appear.

Brain MR Imaging Signature of White and Gray Matter Changes in Hereditary Spastic Paraparesis

Aghakhanyan, G.[1,2]·Vavla, M.[3]·Frijia, F.[2]·Martino, N.[4]·Baratto, A.[4]·De Marchi, D.[2]·De Cori, S.[2]·Lombardo, F.[2]·Paparella, G.[3]·Canapicchi, R.[2]·Martinuzzi, A.[3]·Montanaro, D.[2]
[1]Institute of Life Sciences, Scuola Superiore Sant'Anna, Pisa, ITALY, [2]Fondazione CNR/Regione Toscana G. Monasterio, Pisa, ITALY, [3]Medea Scientific Institute, Conegliano and Bosisio Parini (TV), ITALY, [4]U.O. of Radiology, MRI Unit, O.C.- ULSS7, Conegliano (TV), ITALY.

Purpose
We aimed to investigate voxel-wised changes in gray and white matter microstructures in a group of Hereditary Spastic Paraparesis (HSP) patients (spastic gait locus: SPG4, SPG5, SPG3a, SPG10) and their correlates with clinical scores, disease onset and duration.
Materials & Methods
Diffusion tensor imaging (DTI) and high-resolution T1-weighted structural images were acquired in 14 HSP patients and 14 age-matched controls. Voxel-wise changes in gray matter (GM) volume and topography have been studied by voxel-based morphometry. Two patients were excluded from DTI analysis due to imaging artifacts. Multiple DTI indexes (fractional anisotropy, FA; mean diffusivity, MD; radial and axial diffusivities, RD and AD) were elaborated by tract-based spatial statistic (TBSS), part of FSL 4.1.1v. Data were analyzed accounting age and gender as a nuisance covariates. Family-wise error rate was controlled and significant differences were set up at alpha < 0.05. Correlation analysis were performed between gray/white matter changes and disease onset, disease duration, functional independence measure (FIM) and clinical spastic paraplegia rating scale (SPRS).
Results
We found bilateral GM volumetric reduction restricted in prefrontal cortex (p<0.005, uncorrected). Nevertheless, no cluster was survived after correcting for multiple comparison, probably due to small number of patients. Tract-based spatial statistic analysis revealed widespread alteration of DTI indexes: increase MD (p<0.05, corrected), decrease FA (p<0.01, corrected), and increase RD (p<0.005, corrected). No changes were observed in AD. We identified widespread inverse relationship between FA and SPRS scores (p<0.05, corrected). We did not find any relation between GM reduction and clinical scores, but correlation analysis revealed inverse relationship between reduction of GM volume and disease onset (r = -0.3), but not with disease duration.

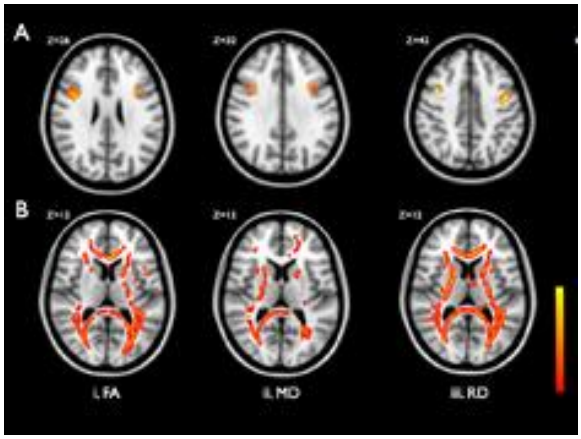

Figure 1: Results of voxelwise analysis showing (A) areas of gray matter volumetric reduction and (B) multiple DTI index maps with decreased FA (i), increased MD (ii) and increased RD (iii) in HSP patients after comparison with age- and sex- matched controls. Results are represented on the MNI152 2mm and 1 mm templates respectively with z axis coordinates (in mm) above each image.
Conclusion
We demonstrated widespread multiple DTI index abnormalities and bilateral clusters of volumetric reduction in prefrontal GM in HSP patients applying quantitative MRI measurements. Fractional anisotropy was voxel-wise correlated with spastic paraplegia rating

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

scale (SPRS), indicating that DTI could be a sensitive MRI marker for clinical severity measurement. More research should be performed to reveal the clinical significance of GM abnormalities in HSP patients.

Late Life Obesity and Brain Structure in a Community Cohort

Raji, C.[1]·Boyle, C.[2]·Erickson, K. I.[2]·Lopez, O.[3]·Becker, J. T.[3]·Gach, H.[3]·Longstreth, W. T.[4]·Kuller, L. H.[5]·Carmichael, O. T.[6]·Thompson, P. M.[2]
[1]University of California Los Angeles, Los Angeles, CA, [2]University of California Los Angeles Medical Center, Los Angeles, CA, [3]University of Pittsburgh Medical Center, Pittsburgh, PA, [4]University of Washington, Seattle, WA, [5]University of Pittsburgh Graduate School of Public Health, Los Angeles, CA, [6]University of California Davis, Davis, CA.

Purpose
Alzheimer disease affects over 30 million persons worldwide and obesity is an important lifestyle factor that can modify risk. We have shown in a smaller study that increased body mass index is associated with lower brain volume in cognitively normal elderly individuals. Here we assessed how higher body mass index affects brain structure in a much larger cohort of elderly individuals who were cognitively normal or had Alzheimer dementia.
Materials & Methods
We studied 963 subjects - 104 with Alzheimer dementia (AD), 135 with mild cognitive impairment (MCI), and 724 healthy elderly controls with an average age of 78 years and age range 69-95 years. These subjects were drawn from the multi-site Cardiovascular Health Study, a population-based cohort study based in Pittsburgh Pennsylvania, Hagerstown Maryland, Winston-Salem North Carolina, and Sacramento California. We acquired volumetric T1-weighted spoiled gradient-echo MR brain images and performed tensor-based morphometry (TBM) to quantitatively assess regional brain volumes. We then performed a multivariate analysis, regressing body mass index (BMI) on brain structure while accounting for covariates including age, sex, diagnosis of MCI or AD, study site, and physical activity as assessed by the number of city blocks walked per week.
Results
People with higher BMI have a greater burden of gray and white matter atrophy and ventricular dilatation, even after controlling for other factors such as age, sex, diagnosis, and study site. Body mass index-associated volume loss is shown in Figure 1. The top row of images represents p-value maps from our analysis and the bottom row represents beta values from the regression analysis. Increased BMI was associated with atrophy in the frontal lobes including the orbital frontal cortex and the cingulate (shown in color). These results did not vary as a function of co-morbid MCI/AD or physical activity.

Conclusion
This is one of the largest-ever voxel-based studies of a human population. Body mass index was associated with brain atrophy with no detectable dependency on diagnosis, and, in this study, no dependence on self-reported physical activity.

KEYWORDS: Alzheimer disease, Brain aging

Should We Assess Atrophy of the Mammillothalamic Tracts in Alzheimer Disease? A Preliminary Study of their Conspicuity and Age-Related Morphometry on Axial 3T MR Imaging

Horsburgh, A.[1,2]·Antoun, N.[1]·Massoud, T. F.[1,3]
[1]Addenbrooke's Hospital, Cambridge, UNITED KINGDOM, [2]Queen's Hospital, Romford, UNITED KINGDOM, [3]University of Cambridge, Cambridge, UNITED KINGDOM.

Purpose
Defining age-related structural alterations in normal brain is an important prelude for studies to identify potential imaging biomarkers for the earlier detection of neurodegenerative disorders. Many limbic structures have been demonstrated to atrophy in Alzheimer disease. It is known that transneuronal degeneration occurs more commonly in "closed neuronal systems" such as the circuit of Papez. Despite existing evidence for atrophy of the fornix and mammillary bodies in Alzheimer disease, and these being part of the Papez circuit, the projections from the mammillary bodies to the anterior thalamic nuclei [i.e., the mamillothalamic tracts (MTTs, bundles of Vicq d'Azyr) have not been studied in Alzheimer disease previously]. The MTTs are known to play a part in memory formation and studies of patients with Wernike's encephalopathy have demonstrated impairment in MTT functional connectivity. Prior preliminary functional MTT studies were performed in humans using diffusion tensor tractography, and limited studies of the MTTs have been performed using conventional structural MRI. We preliminarily studied the conspicuity and age-related

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

changes in the MTTs on axial 3T brain MRI in healthy subjects prior to future evaluation in patients with Alzheimer disease.
Materials & Methods
We retrospectively analyzed the standardized MRI images of 147 patients. We used magnified T2-weighted axial images for analysis of MTT visualization, and specifically assessed conspicuity, signal intensity, size (using electronic callipers), shape, location, and symmetry of the MTTs. We used a Student's *t*-test for independent samples to statistically compare the MTT size in young and older patient groups, with significance at $p<0.05$. The effect of independent variables (gender and side) also was tested on the dependent variable (MTT size) using regression analysis.
Results
The younger age group (<60 years, mean age 39 years) comprised 62 patients (M:F = 50:50), and the older age group (>60 years, mean age 72 years) were 85 patients (M:F = 30:70). Mean transit times were visualized in 85% in the young, and 72% in the older. Etat criblé precluded detection of the MTTs in several of the over 70s. Right MTTs in the young were a mean 1.09 mm^2, and left MTTs were 1.30 mm^2. Right MTTs in the older were a mean 0.87 mm^2, and left MTTs were 1.08 mm^2. None of the independent variables affected variation in MTT size. There were no statistical differences in the MTT sizes between young and older age groups.
Conclusion
This is the first report of baseline age- and gender-related changes in cross-sectional dimensions of the MTTs, made possible by their greater conspicuity on 3T MRI. Additional studies in Alzheimer disease will determine if MTTs characteristics and morphometrics might be useful biomarkers in assessing disease progression and response to potential disease modifying treatments agents.

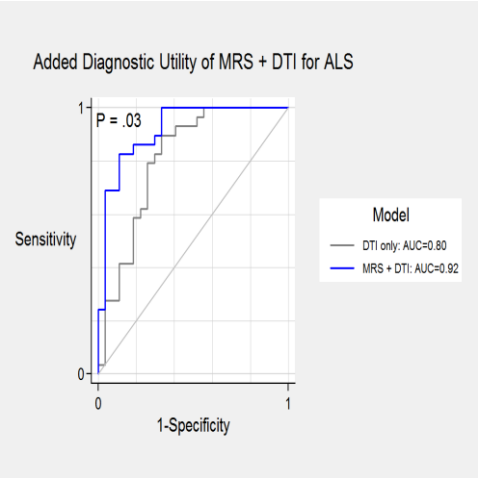
Added Diagnostic Utility of MR Spectroscopy to Diffusion Tensor Imaging in Amyotrophic Lateral Sclerosis

Foerster, B. R.[1]·Carlos, R. C.[1]·Dwamena, B. A.[1]·Petrou, M.[1]·Callaghan, B. C.[1]·Edden, R. A. E.[2]·Mohamed, M. A.[2]·Welsh, R. C.[1]·Barker, P. B.[2]·Feldman, E. L.[1]·Pomper, M. G.[2]
[1]University of Michigan, Ann Arbor, MI, [2]Johns Hopkins University, Baltimore, MD.

Purpose
To explore the added diagnostic utility of magnetic resonance spectroscopy (MRS) including MRS spectral-editing techniques to diffusion tensor imaging (DTI) in the setting of amyotrophic lateral sclerosis (ALS).
Materials & Methods
Twenty-nine ALS patients and thirty age- and gender-matched healthy controls (HCs) underwent 3T DTI as well as short echo time and GABA-edited ^{1}H-MRS centered on the left motor cortex. Subjects also underwent 3T 15 direction diffusion tensor imaging. Tractography of the bilateral corticospinal tracts was performed using ExploreDTI to calculate average fractional anisotropy (FA) values. Data were analyzed using logistic regression, t-tests and receiver operating characteristic curve analyses including leave-one-out cross validation techniques.
Results
Using the DTI FA data (model 1), the area under the curve (AUC) is 0.80. Using DTI, MRS myo-Inositol and MRS GABA data combined (model 2), the AUC is 0.92 and significantly greater than model 1 (P = .03). Model 1 sensitivity, specificity, positive likelihood ratio and negative likelihood ratio values are 0.90, 0.67, 2.72 and 0.15 respectively. Model 2 sensitivity, specificity, positive likelihood ratio and negative likelihood ratio values are 0.83, 0.89, 7.55 and 0.19 respectively.



Conclusion
There is a significant increase in the diagnostic accuracy of advanced MRI techniques to diagnose ALS by combining MRS and DTI techniques. These results indicate that a combination of complementary advanced neuroimaging methods offer significant potential as an ALS diagnostic biomarker although additional research efforts are required for optimization and validation.

Comparison of the Anatomical Volume and Cortical Thickness Measurements between the Subjects with Mild Leukoaraiosis and Control

Liu, H.[1]·Yang, C.[1]·Lee, C.[1]·Chen, S.[2]·Huang, A.[2]·Liu, M.[2]
[1]National Taiwan University Hospital, Taipei, TAIWAN, [2]Center for Dynamical Biomarkers and Translational Medicine, National Central University, Jhongli, TAIWAN.

Purpose
FreeSurfer is a well known software package to measure cerebral cortical volume and thickness. Leukoaraiosis is the nonspecific changes in the cerebral white matter frequently seen on CT and MRI in aged individuals. Mild leukoaraiosis is a common finding in subjects after mid-age.
Materials & Methods
We compared the results of cerebral cortex and volume in different anatomical locations in 48 subjects with mild leukoaraiosis shown on the FLAIR and T2-weighted images to 67 subjects with normal MR images. They were 75 women (normal = 43, mean age = 54.0 years old, SD = 8.9; leukoaraiosis = 32, mean age = 62.7 years old, SD = 8.9) and 40 men (normal = 24, mean age = 52.0 years old, SD = 8.9; leukoaraiosis = 16, mean age = 61.8 years old, SD = 6.3). The periventricular hyperintensity and deep white matter hyperintensity were graded according to Fazekas et al. The exclusion criteria; evidence of psychiatric illness within the past two years, including substance abuse, a history of recreational drug use in the previous six months, a history of CNS disease or brain injury, any MR imaging abnormality checked by two experienced neuroradiologists. MR scans were acquired with a 1.5T scanner (GE Healthcare, Wisconsin, USA). Coronal T1-weighted images were obtained using an MP-RAGE sequence with TR = 8.9 msec, TE = 2.99 msec, TI = 600 ms and a flip angle of 12. The slice thickness was 0.9 mm with no interslice gap. The image matrix was 256 x 256.
Results
No statistic difference between the two groups in age. On cortical volume measurement in left cerebral hemisphere, the measurement was significantly smaller in leukoaraiosis group in six regions (precuneus, lateral orbital frontal, superior parietal, superior frontal, rostral middle frontal, and pars opercularis), and significantly larger in eight regions (pericalcarine, inferior temporal, pars triangularis, postcentral, isthmus cingulate, superior frontal, insula, and medial orbitofrontal). In the right hemisphere, the measurement was significantly smaller in leukoaraiosis group in six regions (precuneus and isthmus cingulated), and significantly larger in 10 regions (pericalcarine, posterior cingulate, insula, inferior parietal, cuneus, parahippocampal, inferior temporal, inferior parietal, and caudal anterior cingulate). On cortical thickness measurement in left cerebral hemisphere, the measurement was significantly smaller in leukoaraiosis group in four regions (precuneus, superior parietal, superior frontal, and pars opercularis), and significantly larger in nine regions (pars triangularis, isthmus cingulate, inferior temporal, caudal anterior cingulated, insula, precentral, rostral middle frontal, medial orbitofrontal, and pericalcarine). In the right hemisphere, the measurement was significantly smaller in leukoaraiosis group in one region (supramarginal), and significantly larger in five regions (pericalcarine, insula, precuneus, posterior cingulate, and inferior parietal).
Conclusion
Leukoaraiosis has effect on the cortical volume and thickness. The change is variable in different locations.

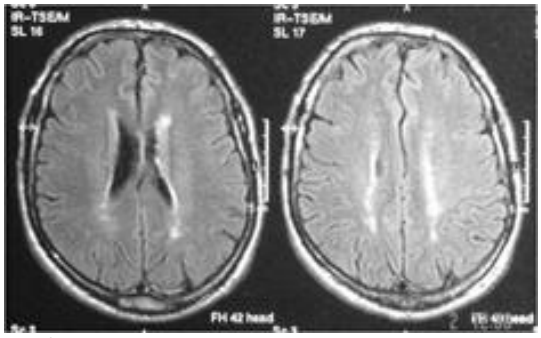
MR Imaging Findings in Anderson-Fabry Disease

Borri, M. L.[1]·Mendes, C. S. C.[2]·Rand, M. H.[2]·Feliciano, P.[2]·Kyosen, S. O.[2]·Wolosker, A. M. B.[1]·Martins, A. M.[3]
[1]UNIFESP - São Luiz - Fleury, São Paulo, BRAZIL, [2]IGEIM, São Paulo, BRAZIL, [3]IGEIM - UNIFESP, São Paulo, BRAZIL.

Purpose
Anderson-Fabry disease (AFD) is an X- linked glycosomal storage disorder caused by deficiency of alpha-galactosidase A. As a consequence, there is accumulation of glycosphingolipids in blood vessels, central and peripheral autonomic nervous system. In the central nervous system, diffuse storage occurs in the cerebral vasculature and neurons. Brain MRI often are abnormal. Neuroradiologic findings include periventricular white matter signal intensity abnormalities, lacunar infarcts, large ischemic cerebral infarctions, and posterior thalamus involvement so-called “pulvinar sign“. The aim of the study was to describe brain MRI findings of 10 patients with AFD, seven male patients and three female patients, ages 12 to 60 years old (median age 34.7 years).
Materials & Methods
The brain MRIs of 10 patients were analyzed retrospectively. Seven patients were under treatment with enzyme replacement therapy (ERT).
Results
Brain MRIs were abnormal in all patients. The most frequent finding was Virchow-Robin spaces enlargement in six patients (4 M/2 F). Mild cortical atrophy was present in five (4 M/1 F), calcification or metallic deposits in deep gray matter (1 M/ 1 F), cerebral atrophy and microangiopathy in two males; hypersignal in FLAIR/T2 in pulvinar in three male patients, white matter lesion in four (2 M/2 F); enlargement of lateral ventricles in three (1 M/2 F); microcalcifications in left thalamus in one female patient, hypersignal in T1 in pulvinar, and hypersignal in T2 in medium cerebral peduncle in one male patient.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Conclusion
We evaluated 10 patients with AFD to describe neuroradiologic findings. The MR imaging studies described images mainly in small vessel pathology, but no large stroke. All images had alterations, mainly in older patients. The presentation of this disease may be sudden or gradual, and the features permanent or transient, often with exacerbations affecting distant parts of the nervous system, making the diagnosis difficult. MR images are now recognized to be the method of choice and important in monitoring patients with AFD in all ages.

KEYWORDS: Metabolic, Microvascular disease, MRI pulvinar sign

Stem Cell Effect on Cognitive Status of Patients with Multiple Sclerosis

Sych, N. S.
Cell Therapy Center EmCell
Kiev, UKRAINE.

Purpose
Cognitive impairments in multiple sclerosis (MS) traditionally have received little attention, although they are different and rather frequent (45-70% of cases). Marked intellectual impairment (dementia) occurs at later stages of MS, in 20-30% of cases. Goal: Study effects of fetal stem cells on cognitive impairment in MS patients.
Materials & Methods
The study included 27 MS patients, 12 men and 15 women aged 24 - 59 years (mean age 42, 23 ± 9.04 years), with 6-10 years of disease history: relapsing-remitting - 14, secondary-progressive - 8, progressive remitting - 2, primary progressive - 3. EDSS score varied from 3.5 to 6.5 points. Multiple sclerosis was confirmed in accordance to McDonald's criteria. Mini-Mental State Examination (MMSE) and Isaac's test were used for neuropsychologic examination. All patients underwent transplantation of hematopoietic and nonhematopoietic fetal stem cells (FSC) harvested from germ layers of internal organs of 4-8 weeks old legally aborted fetuses. Neurologic checkup and neuropsychologic assessment were performed before FSC transplantation and three months after the treatment. For ethical reasons, effectiveness of the previous treatment was the major selection criterion as patients were resistant to most conventional MS therapies [MS disease modifying drugs (Copaxone, Avonex, Betaferon), corticosteroids, plasmapheresis]. Statistical processing was performed with Statistika v.6.0.
Results
Fetal stem cell treatment resulted in significant cognitive improvements on MMSE - 26.95 ± 0.30 versus 23.89 ± 0.51 at baseline, $p < 0.05$. The Isaacs Set Test (IST) assessed verbal fluency by measuring the ability to generate lists of words in four semantic categories. In MS patients, the average before the treatment was 31.6 ± 6.0 out of 40 points, and it increased to 35.9 ± 2.5 three months after the treatment, $p < 0.05$.
Conclusion
Fetal stem cell treatment resulted in significant cognitive improvement on MMSE and IST. Our experience showed that FSC therapy is a promising method of treatment for MS patients with cognitive impairment. Cognitive improvement in these patients can be associated with improved cerebral circulation and capillary network development.

New-Onset Seizures: Appropriate Workup and Example Etiologies

Spirer, D. J.·Gorman, D.·Nemeth, A. J.
Northwestern University
Chicago, IL.

Purpose
This education exhibit will discuss a work-up plan for a patient with a clinical presentation of "new-onset seizures" and numerous pathologies that can result in new-onset seizures.
Materials & Methods
From the available neurology and radiology literature, we collected imaging of numerous etiologies that may result in new-onset seizures. The cases were culled from a combination of patients with a history of new seizure activity encountered during clinical practice, and also utilizing a database search of the electronic medical record for cases illustrative of possible etiologies of new-onset seizures. Additional background information was obtained from the neurology faculty who specialize in epilepsy.
Results
When faced with the clinical information of a patient who presents with new-onset seizures, a first step per the American Academy of Neurology practice guidelines is to obtain an immediate noncontrast CT in the emergency setting (Neurology 2007; 69: 1772-1778). This will guide appropriate acute management, especially if there is an abnormal neurologic examination, predisposing history, or focal seizure onset. Following the acute setting, brain imaging with MR imaging pre and postcontrast with the

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

minimum axial T1 pre and postcontrast, T2, FLAIR, and diffusion imaging was found to be helpful. Coronal T1, T2, FLAIR imaging is additionally useful to evaluate for developmental abnormalities, mesial temporal sclerosis, temporal or frontal lobe abnormalities. New-onset seizures can have numerous etiologies. A categorization divides etiologies into primary neurologic disorders and systemic disorders. Primary neurologic disorders include: idiopathic epilepsy, febrile seizures, trauma, stroke, mesial temporal sclerosis, gray matter heterotopia or other developmental abnormalities, vascular malformations, mass lesions, infection including meningitis, encephalitis, or HIV encephalopathy. Systemic etiologies are many and include electrolyte abnormalities, metabolic derangements, organ failure, drug toxicities, global ischemia, hypertensive encephalopathy, eclampsia, hyperthermia, and porphyria.

Conclusion

New-onset seizures are a common reason for neurologic imaging. The radiologist should recommend a CT in the emergency setting and follow-up MR imaging to obtain more details. Etiologies include primary neurologic disorders and systemic disorders. There are numerous potential etiologies for seizure activity that should be considered in the differential diagnosis when evaluating the imaging findings. These etiologies have traditionally been discussed individually, and in this educational exhibit, our approach is to explore what various pathologies a radiologist may expect to find at imaging given the clinical presentation of new-onset seizures.

Characterization of Focal Cortical Dysplasia Using Diffusion-Weighted Imaging

Steeman, R. R. M.[1]·Besseling, R. M. H.[1]·Damen, M. M. J.[2]·Hoeberigs, M. C.[1]·Jansen, J. F. A.[1]·Backes, W. H.[1]·Hofman, P. A. M.[1,3]
[1]Maastricht University Medical Center, Maastricht, NETHERLANDS, [2]Máxima Medical Center, Veldhoven, NETHERLANDS, [3]Epilepsy Centre Kempenhaeghe, Heeze, NETHERLANDS.

Purpose

Epilepsy is one of the common neurologic syndromes with a lifetime incidence of 2-4%: approximately 50% of these patients suffer from partial seizures. Neuroimaging is used to determine cortical (gray matter) abnormalities related to these seizures. However, in up to 74% of patients with location related (partial) seizures, MRI shows no abnormalities. It is assumed that the majority of these patients have a small focal cortical dysplasia. Detecting these lesions is of clinical importance since in patients with intractable epilepsy, resection may be the only viable therapeutic option, with excellent prognosis for seizure control. The goal of this study is to achieve a more sensitive method for detecting malformations of cortical development by using diffusion-weighted (rather than conventional structural) imaging (DWI) to assess the possible extension of focal cortical dysplasias (FCDs) in the underlying white matter (WM).

Materials & Methods

Sixteen FCD patients underwent MR imaging at 3T including T1 and FLAIR sequences and DWI (128 gradient directions, b=1500s/mm^2) for diffusion tensor imaging (DTI) and tractography. A white matter segmentation mask was employed to confine the region of interest (ROI) to white matter only. Three patients were excluded because the ROI in the dysplasia was outside the WM-mask. A systematic pattern of spherical ROIs was placed in and around the FCD as seen on FLAIR. Contralateral homologues ROIs were defined using landmarks on structural scans and tractograms to bilaterally match the cortical folding as well as the underlying fiber architecture. The extent of FCDs was investigated using concentric expansion of the ROIs. We evaluated fractional anisotropy (FA) and apparent diffusion coefficient (ADC) of the ROIs.

Results

In the center of the FCD, with respect to contralateral normal-appearing white matter, the ADC values were increased in 11/13 patients and the FA values were decreased in 10/13. These effects were significant at the group level (paired t-test, p=0.013 and p=0.047, respectively). In the surrounding tissue, ADC values were increased in 15/57 (26%) of the ROIs ($p<0.05$), and FA was decreased in 10/57 (18%) of ROIs ($p<0.05$). Apparent diffusion coefficient values were decreased in 9/57 (16%) and FA values in 1/57 (2%). There was no significant extent of DWI abnormalities beyond the lesions visible on FLAIR images.

Conclusion

Within FCD, aberrant diffusion properties (increased ADC values and decreased FA values) were measured. No DTI abnormalities were found in surrounding tissue and no significant extent of the lesion on DWI compared to the conventional structural imaging was measured. After optimizing ROI positions using tractography and anatomical landmarks, no interhemispheric differences in FA and ADC were observed outside the FLAIR-derived lesion. This implies the application of simple DTI measures does not increase the sensitivity for the detection of FCDs. Our findings confirm the hypothesis that FCDs are localized lesions, which also is supported by the good seizure outcome after focal resection. This does not fully preclude underlying white matter abnormalities and other, more complex, diffusion properties such as apparent fiber density (AFD) or kurtosis may reveal more subtle white matter abnormalities related to FCD.

Functional Integrity Markers in Epilepsy from Functional MR Imaging at Rest

Ascencio, J.[1]·Ochoa, J.[1,2]·Velásquez, J.[3]
[1]Instituto Neurológico de Colombia, Medellin, COLOMBIA,
[2]Universidad de Antioquia, Medellín, COLOMBIA,
[3]Universidad de Antioquia, Medellin, COLOMBIA.

Purpose
To present the findings in a group of patients with epilepsy from functional MRI at rest using two techniques: (i) functional connectivity measured by graph theory and (ii) neuronal activity index from fractional Amplitude of Low-Frequency Fluctuation (ALFF).
Materials & Methods
Using equipment operating at 1.5T and 3T (Siemens, Erlangen) volumetric sequence (MPRAGE TR = 11 ms, TE = 5.2 ms, FA = 15, thickness = 1 mm, matrix = 224 x 256, 176 slices per volume) and T2 EPI sequence sensitive to BOLD effect (TR = 2700 ms, TE = 30 ms, FA = 90, thickness = 3 mm, matrix = 64 x 64, 32 slices per volume covering the entire cerebral cortex) in 20 lesional epilepsy patients divided into two groups: 10 with epilepsy for hippocampal sclerosis and 10 extratemporal epilepsy were performed. Maps of fALFF are calculated from functional imaging, using the tool DPARSFA, and maps of the measure of the degree obtained by graph theory using our own algorithms. The proposed graph has 20092 nodes corresponding to all of the cerebral gray matter from a resolution of 4 mm. For comparison we used masks defined in AAL atlas and compared, for all the patients, the lesional region against his contralateral region.
Results
In all patients the degree value is decreased in the lesional area. The reduction allows significant asymmetry indices between the lesional region and the contralateral region to be obtain. The asymmetry obtained by fALFF is not significant for the subjects studied.
Conclusion
The analysis of the morphology of the BOLD signal in the epileptogenic area, evaluated indirectly in the graphs approach through the correlation of pathologic signal against all the other signals in the cerebral cortex, is a better marker of neuronal dysfunction than the neuronal activity index measured by fALFF.

Opposite Effects on White Matter Microstructure of Reciprocal Deletions versus Duplications at the 16p11.2 Chromosomal Locus

Owen, J. P.·Bukshpun, P.·Pojman, N.·Sherr, E.·Mukherjee, P.
University of California San Francisco
San Francisco, CA.

Purpose
The chromosomal region 16p11.2 is strongly linked to autism, schizophrenia and other neurologic disorders caused by deletions or duplications at this locus. There is evidence of “mirroring” in the phenotypes of deletion mutations versus duplication mutations; for instance, individuals with deletions are more likely to have macrocephaly and be overweight, while individuals with duplications tend to have smaller head sizes and be thin. In this study, we use diffusion-tensor imaging (DTI) to investigate abnormal white matter microstructure associated with 16p11.2 duplications and deletions.
Materials & Methods
3T DTI was acquired in 10 subjects with 16p11.2 duplication (mean age 34.5±15.9 years, eight male) and 11 subjects with 16p11.2 deletion (mean age 21.3±14.5, five males). Twenty-one healthy controls matched for age and gender with the probands also were imaged. Diffusion tensor was performed at 2.2mm isotropic voxel resolution with 64 encoding directions at b = 1000 s/mm2. FSL was used to calculate fractional anisotropy (FA), axial diffusivity (AD) and radial diffusivity (RD). Nonparametric permutation testing from tract-based spatial statistics (TBSS) was used to detect significant group differences in the white matter of the whole brain ($p<0.05$), corrected for multiple voxel-wise comparisons with threshold-free cluster enhancement.
Results
We found opposite changes in white matter microstructure of the duplication and deletion cohorts. The duplications have decreased FA compared to matched controls in the body of the corpus callosum and the right forceps major as shown in Figure 1(a). Significantly increased RD also was detected in these regions. Conversely, the deletions have increased FA throughout the supratentorial white matter compared to matched controls, including the corpus callosum, internal capsule, anterior thalamic radiations, and superior longitudinal fasciculus, as shown in Figure 1(b). Axial diffusivity was also significantly increased in the majority of the same voxels.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

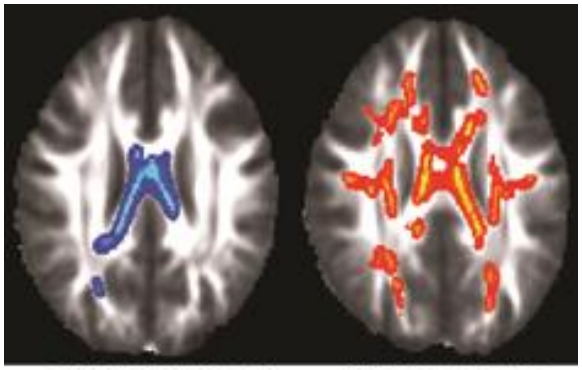

Figure 1: White matter voxels with significantly decreased FA in duplications in blue (a) and significantly increased FA in deletions in red (b).

Conclusion

To our knowledge, this is the first demonstration of mutations at the same genetic locus producing opposite effects on white matter anisotropy. Hence, the "mirror phenotypes" of 16p11.2 deletions versus duplications seem to extend to the microstructure of white matter. Although abnormally reduced FA is found in many disorders, the finding in 16p11.2 deletions of abnormally elevated FA is rare. One such recent example, although with much less spatial extent of increased anisotropy, is Williams syndrome. This work motivates further research into how genes at the 16p11.2 locus govern white matter microstructure and also into how these gene-brain relationships affect behavior and cognitive abilities in subjects with 16p11.2 mutations.

P-18

Evaluation of Hemodynamic Status and Vasodilatory Capacity to Hypercapnia State: Value of Arterial Spin Labeling Perfusion and Susceptibility-Weighted Imaging on 3T

Kishi, T.･Iida, E.･Furukawa, M.･Kato, M.･Matsunaga, N.
Yamaguchi University
Ube, JAPAN.

Purpose

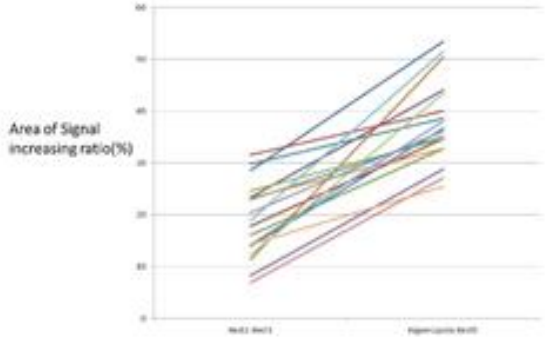
Hypercapnia state is known as a factor that increases the cerebral blood flow (CBF). The purpose of this study is to assess the quantitative analysis using arterial spin labeling (ASL) perfusion and susceptibility-weighted image (SWI) for evaluating hemodynamic status and vasodilatory capacity under hypercapnia and resting state with monitoring end-tidal CO_2($ETCO_2$).

Materials & Methods

Twenty-one healthy volunteers (14 men, 7 women; mean age of 28 years) underwent ASL perfusion and SWI on 3T MRI under two resting states (resting 1 and resting 2) and hypercapnia state. Hypercapnia state was induced by hypoventilation with monitoring $ETCO_2$. On ASL perfusion, CBF values in hypercapnia and resting state were recorded at the level of corona radiata. Then the increase rate of CBF (%ΔCBF) between hypercapnia and resting state was calculated. On SWI, the average signal intensity of the whole brain parenchyma was recorded at the same level for both hypercapnia and resting state. The signal intensity ratio was compared among hypercapnia, resting 1, and resting 2. Using subtraction images, the area of signal increase between hypercapnia state and resting 1 was compared with that between resting 2 and resting 1.

Results

Mean $ETCO_2$ was 35.7 mmHg in resting 1, 36.0 mmHg in resting 2, and 44.3 mmHg in hypercapnia state. Mean $ETCO_2$ in resting 1 and resting 2 was not significantly different (P = 0.25). CBF in hypercapnia state was significantly higher than CBF in resting 1 (27.7 ml/100g/min and 22.5 ml/100g/min , respectively: P<0.001). %ΔCBF between hypercapnia and resting 1 was 24.9 ± 17.7%. On SWI, signal intensity ratio between hypercapnia state and resting 1 was 1.48 ± 1.64%, which was significantly higher than that between resting 2 and resting 1 (-0.37 ± 0.91%: P<0.001). On subtraction images, area of signal increase was 37.9 ± 8.0% between hypercapnia state and resting 1, which was significantly larger than that between resting 2 and resting 1 (18.8% ± 7.3 %: P<0.001).



Conclusion

Arterial spin labeling perfusion and SWI combined with hypercapnia state are less invasive valuable tools to assess the hemodynamic status. Subtraction image of SWI sensitively reflects the area of increased CBF and vasodilatory response.

Structural Connectome of the Human Brain in Agenesis of the Corpus Callosum

Owen, J. P.[1]·Li, Y.[1]·Ziv, E.[1]·Strominger, Z.[1]·Gold, J.[1]·Bukshpun, P.[1]·Wakahiro, M.[1]·Friedman, E.[2]·Sherr, E.[1]·Mukherjee, P.[1]
[1]University of California San Francisco, San Francisco, CA, [2]University of California Berkeley, Berkeley, CA.

Purpose
Adopting a network perspective, the structural connectome reveals the large-scale white matter connectivity of the human brain. Connectomics has great potential for elucidating abnormal connectivity in congenital brain malformations, especially axonal pathfinding disorders. Agenesis of the corpus callosum (AgCC), a prototypical human disorder of axon guidance, is one of the most common brain malformations. In AgCC the fibers that would normally have comprised the corpus callosum instead form Probst bundles, large white matter tracts that course anterior-posterior within each cerebral hemisphere. In this exploratory study, the structural connectome of AgCC is mapped and compared to that of the normal human brain.
Materials & Methods
Seven subjects with AgCC (four male, three female; mean age 24.3 ± 14.2 years) and 11 healthy volunteers (six male, five female; mean age 24.9 ± 9.1 years) were included in this study. Diffusion imaging was performed at 3T with 55 diffusion-encoding directions, at b = 1000 s/mm^2, and 1.8 mm isotropic resolution. FREESURFER was used to segment each subject's T1-weighted MRI; into cortical and subcortical labels. These labels were used as seed regions for probabilistic tractography using FSL's probtrackx2 to create whole brain connectomes. The network measures (degree, betweenness, clustering coefficient, local efficiency, efficiency, cost, and characteristic path length) were computed for the individual networks in each group and statistics were used to assess group differences. We also calculated metrics of consistency for the connection strengths and module assignments. We tested for statistically significant different connection strengths in one module, the “structural core” of the cerebral cortex. A “virtual Probstotomy” was performed on the AgCC subjects to assess the contribution of the Probst bundles to the AgCC connectome.
Results
Our quantitative investigations reveal four major findings. First, global connectivity is abnormally reduced in AgCC, but local connectivity is increased (Table 1). Second, the network topology of AgCC is more variable in both the connection strengths and the module assignments than that of the normal human connectome. Third, modularity analysis reveals that many of the tracts that comprise the structural core of the cerebral cortex have relatively weak connectivity in AgCC, especially the cingulate bundles bilaterally. Finally, virtual lesions of the Probst bundles in the AgCC connectome demonstrate that there is consistency across subjects in many of the connections generated by these ectopic white matter tracts, and that they are a mixture of cortical and subcortical fibers.

Network Metric	Control	AgCC
Mean degree	17.7±2.2	16.7±2.6
Characteristic path length	1.98±0.09	2.21±0.10*
Mean normalized betweenness	0.025±0.002	0.031±0.002*
Global efficiency	0.57±0.03	0.53±0.03*
Mean local efficiency	0.79±0.01	0.83±0.03*
Mean clustering coefficient	0.59±0.02	0.67±0.04*

Table 1: Network metrics applied to individual connectomes,
* denotes statistically different than controls (p<0.05)

Conclusion
Together, these observations demonstrate that structural connectivity in AgCC is much more complex than is currently understood from prior studies using gross anatomical imaging or even diffusion tractography studies of specific fiber pathways. Connectomics has great potential to more comprehensively elucidate the malformed human brain and advance our understanding of normal and abnormal brain development.

Association between Clinical Measures and Florbetapir F18 PET Amyloid Neuroimaging in Mild and Moderate Alzheimer Dementia

Witte, M. M.[1]·Trzepacz, P.[1,2]·Case, M.[1]·Yu, P.[1]·Hochstetler, H.[1]·Quinlivan, M.[3]·Sundell, K.[4]·Henley, D.[4,2]
[1]Lilly USA, LLC, Indianapolis, IN, [2]Indiana University School of Medicine, Indianapolis, IN, [3]Eli Lilly Australia, West Ryde, AUSTRALIA, [4]Lilly Research Laboratories, Indianapolis, IN.

Purpose
Alzheimer disease (AD) is challenging to diagnose clinically, with the sensitivity of clinical criteria by experts reported to range from 71-87% and specificity from 44.3-70.8%. We compared demographic and neuropsychiatric

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

characteristics between those with and without PET evidence of amyloid plaque in clinically-diagnosed AD dementia patients recruited for clinical trials. We sought to identify clinical variables to identify patients at risk of being mistakenly diagnosed with AD.
Materials & Methods
A subset of patients (199/2,648) pooled from two AD anti-amyloid drug trials with identical inclusion criteria participated in an optional amyloid-PET neuroimaging addendum with florbetapir F18 (FBP). The trials enrolled patients ≥55 years of age with clinically-diagnosed mild or moderate AD dementia using NINCDS/ADRDA criteria. Exclusion criteria included stroke, unstable medical illness, substance abuse/dependence, major depression, or vascular dementia. Prior to receiving study drug, patients underwent FBP-PET and were administered the following rating scales: Alzheimer's Disease Assessment Scale-cognitive subscale 14-item version (ADAS-Cog14), Alzheimer's Disease Cooperative Study Activities of Daily Living Inventory (ADCS-ADL), Clinical Dementia Rating (CDR), Mini Mental-State Exam (MMSE), 12-item Neuropsychiatric Inventory (NPI-12), and Geriatric Depression Scale (GDS). Patients with a composite cortical (frontal, temporal, parietal , precuneus, anterior cingulate, and posterior cingulate regions) standardized uptake value ratio (SUVR) <1.1 using whole cerebellum as the reference region were categorized as having a negative scan. Categorical data were compared using Fisher's exact test, means using ANOVA.
Results
In this clinically-diagnosed sample, 35 (18%) patients were FBP-PET negative for amyloid plaque. These patients performed significantly better than FBP-PET positive patients on the ADAS-Cog14 [mean (SD, range): 26.8 (12.4, 8 - 63) vs. 34.1 (10.7, 11-63); p<.001] and the MMSE [mean (SD, range): 24.0 93.21, 15 - 300 vs. 21.0 93.98, 13-300; p<.001] and were significantly more likely to be categorized as having mild dementia (86% vs. 59%, p=.003). FBP-PET negative patients performed statistically worse on the GDS [mean (SD, range): 2.23 (1.70, 0 - 6) vs. 1.51 (1.42, 0 - 7); p=.010], although the scores were well below the cutoff for syndromal depression. No differences were found on the ADCS-ADL, CDR, or NPI-12. Patients in the two groups had similar mean age and years of education, though a greater proportion of FBP-PET negative patients were male (63% vs. 42%; p=.039). A significantly lower proportion of FBP-PET negative patients were carriers for the ApoE4 allele (heterozygous/homozygous: 15%/3% vs. 47%/21%; p<.001). Neither age (r= -0.002; p=.980) nor years of education (r=-0.008; p=.915) were found to correlate significantly with SUVR.
Conclusion
Although diagnosed by expert clinicians, about 18% of patients in this study had FBP-PET results inconsistent with a diagnosis of AD. While these groups were significantly different on some cognitive measures and APOE4 status, there was a large degree of overlap in the results such that no variable could be relied upon by clinicians to distinguish the subgroup of patients who appear to have AD but in fact lack corresponding AD neuropathology. This study highlights the importance of amyloid neuroimaging in the AD diagnostic matrix, even during diagnosis by dementia experts.

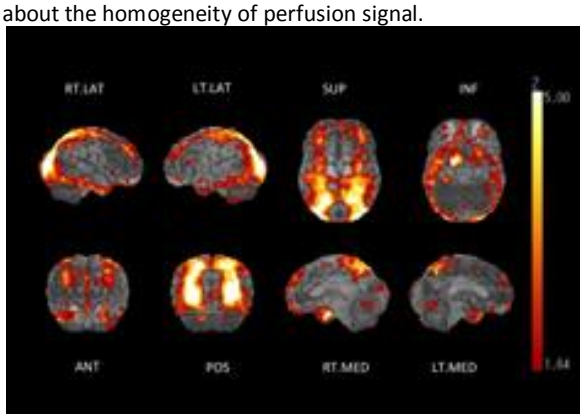
P-21

Underestimation of Regional Cerebral Blood Flow by Arterial Spin Labeling MR Imaging in Elderly Persons

Wada, A.·Hara, A.·Ohsone, F.·Kitahara, H.·Matsunaga, H.·Yamamoto, K.·Okubo, T.
Teikyo University Chiba Medical Center
Ichihara, JAPAN.

Purpose
In arterial spin labeling (ASL), post labeling delay (PLD) has a major influence to the regional cerebral blood flow (CBF) measurement. In elderly, aging-related change extends the arterial transit time (ATT) and an adaptation of inadequate PLD, which is shorter than ATT, may underestimate the regional CBF. This study aimed to investigate the validity of the conventional PLD setting in healthy elderly and suggest an efficacy of longer PLD adaptation.
Materials & Methods
Quantitative CBF measurement with ASL was performed in 11 healthy elderly (three male, eight female, mean age 65.5 years) with two different PLD (conventional 1525 msec and longer 2525 msec). ASL was performed with pulsed continuous labeling technique by using 3T MR unit. Group analysis with paired t-test was performed about regional CBF value at 18 region of interest set to the standardized three-dimensional CBF data by NEUROSTAT software. P value < 0.05 was defined as a statistically significant difference.
Results
Only conventional PLD revealed a hypo-perfusion at lateral parietal lobe and occipital lobe and significant difference of regional CBF value was recognized associated with PLD difference (p<0.05). Moreover, longer PLD was superior about the homogeneity of perfusion signal.



Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

(Figure) Result of group analysis with paired t-test of regional CBF quantitation. Surface projection of Z-score on standard brain shows the relative hypo-perfusion area in conventional PLD of 1525 msec compared with longer PLD of 2525 msec. Significant relative hypoperfusion is represented at bilateral parietooccipital lobes.

Conclusion

In elderly, ASL with conventional PLD may induce a false hypo-perfusion at rostral region of the brain. This underestimation may impair the ASL diagnosability about cognitive disorders (such as Alzheimer disease, Lewy body disease and Parkinson disease). In elderly, longer PLD is recommended as a default setting of ASL.

Test-Retest Reliability of Computational Network Measures Derived from the Structural Connectome of the Human Brain

Owen, J. P.[1]·Ziv, E.[1]·Bukshpun, P.[1]·Pojman, N.[1]·Wakahiro, M.[1]·Berman, J.[2]·Roberts, T.[2]·Sherr, E.[1]·Mukherjee, P.[1]
[1]University of California San Francisco, San Francisco, CA, [2]Childrens Hospital of Philadelphia, Philadelphia, PA.

Purpose

Structural MR connectomics holds promise for improving diagnosis, outcome prediction and treatment monitoring of many neurodevelopmental, psychiatric and neurodegenerative disorders for which there is currently no clinical utility of MR imaging. Before network metrics computed from a particular processing pipeline can be applied in a clinical setting, the precision and normative intersubject variation must be understood. The reproducibility of commonly used graph theoretic measures is investigated, as applied to the structural connectome of healthy adult volunteers, using standard MRI acquisition parameters and a widely used connectome processing pipeline.

Materials & Methods

Ten healthy control subjects were scanned twice at Site 1 and five healthy controls were scanned once at Site 1 and once at Site 2. MR imaging was performed on a 3T TIM Trio MR scanner(Siemens, Erlangen, Germany) at each site. Whole-brain diffusion imaging was performed with 30 diffusion-encoding directions, at b=1000 s/mm^2, and 2mm isotropic resolution. FSL's probtrack2 was used to perform probabilistic HARDI tractography to create whole-brain connectomes. Global graph metrics: mean degree (K), characteristic path length (L), clustering coefficient (C), mean betweenness (B), global efficiency (E), and mean local efficiency (E_{loc}) are calculated for unweighted and weighted connectomes and at two levels of granularity of the connectome: 82-node parcellation from FreeSurfer and atlas-free parcellation consisting of 1000 cortical nodes. Intraclass correlation coefficient (ICC) and coefficient of variation (CV%) were used as measures of precision and variability. The consistency of the unweighted and weighted edges and the module assignments also are computed for the 82-node connectomes.

Results

In Table 1, we report low CV% and high ICC values for the unweighted network metrics applied to both the 82-node and 1000-nodes connectomes. Only ICC and CV% for C and E calculated for the 82-node connectomes (intrasite) are not significant. The weighted metrics have similar CV% and ICC values, although weighted characteristic path length stands out as a less reproducible metric with a CV% of 34.75 for the 82-node connectome. We also find that the unweighted and weighted edges and module assignments are reproducible intra and intersite.

	82-Node Connectome		1000-Node Connectome	
Intrasite	CV%	ICC	CV%	ICC
K	3.21*	0.89*	2.89*	0.78*
L	1.44*	0.92*	2.96*	0.79*
C	3.40	0.51	1.12*	0.78*
B	2.73*	0.90*	4.89*	0.79*
E	1.18*	0.92*	2.58*	0.78*
E_{loc}	1.79	0.54	0.42*	0.75*
Intersite	CV%	ICC	CV%	ICC
K	6.26*	0.79*	3.81*	0.89*
L	2.26*	0.82*	1.98*	0.94*
C	3.05	0.59*	0.94*	0.88*
B	4.00*	0.82	3.31*	0.94*
E	1.94*	0.84*	1.74*	0.94*
E_{loc}	1.61	0.63*	0.42*	0.87*

CV% and ICC values for unweighted network metrics, * denotes p<0.05.

Conclusion

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Overall, the results demonstrate good to excellent test-retest reliability for the graph analytics in both the intrasite and intersite datasets. The weighted and unweighted global network metrics applied to the 1000-node connectome yield better reproducibility than as applied to the 82-node connectomes. ICC and CV% values indicate, in general, better reproducibility and precision than the findings of other connectome variability papers. This improvement is most likely due to methodologic differences, including tractography algorithm and thresholding. The findings reported here indicate that computational network metrics from this structural connectome pipeline have sufficient precision to be tested as potential biomarkers for diagnosis, prognosis, and monitoring of interventions in neurologic and psychiatric diseases.

Patterns of Diffusivity Changes at the Anterior Cingulum in Patients with Dementia with Lewy Bodies and Alzheimer Disease: Diffusion Tensor Imaging Analysis

Suzuki, M.[1]·Motoi, Y.[1]·Kamagata, K.[1]·Kosuge, M.[1]·Kamiya, K.[1,2]·Sato, K.[1,2]·Shimoji, K.[1]·Hori, M.[1]·Nakanishi, A.[1]·Sasai, K.[1]·Hattori, N.[1]·Aoki, S.[1]
[1]Juntendo University, Bunkyo-ku Tokyo, JAPAN, [2]Tokyo University, Bunkyo-ku Tokyo, JAPAN.

Purpose
To identify the patterns of diffusivity changes at the anterior cingulum in patients with dementia with Lewy bodies (DLB) and Alzheimer disease (AD) and to determine whether diffusion tensor MRI (DTI) is complementary to structural MRI in depicting the tissue abnormalities characteristic of DLB and AD.
Materials & Methods
We studied clinically diagnosed age-, gender-matched subjects with DLB (n = 8), subjects with AD (n = 16) in a case-control study. The brains of all patients were examined with a 3T MR imaging unit and an 8-channel array-receiving head coil for sensitivity encoding parallel imaging. After regular structural images acquisition, diffusion tensor images were obtained. Maps of FA and MD were computed by using dTV II and Volume-One 1.72 (http://www.volume-one.org), developed by Masutani, et al. We performed diffusion tensor tractography of the anterior and posterior cingulate fiber tracts (CFTs) and also the corticospinal tracts as a control procedure. Tract measurements performed by two of the authors, were blinded to the disease status of the subjects. The anterior and posterior CFTs were voxelized, and mean diffusivity (MD), fractional anisotropy (FA), axial diffusivity (AD), radial diffusivity (RD) values in co-registered voxels were calculated. Student's *t*-test was used to compare the averaged values of MD, FA, AD, and RD between DLB patients and AD patients. A Bonferroni correction was applied for the number of comparisons (n = 2: (anterior CFTs, posterior CFTs), setting the level of significance at $P < 0.05/2 = 0.025$).
Results
Fractional anisotropy and RD measured in the anterior CFTs was significantly lower in patients with DLB compared with AD (P = .022, 0.004, respectively). There were no significant diffusion differences in the posterior CFTs, corticospinal tracts between the groups.
Conclusion
Diffusivity measurements were complementary to structural MRI, demonstrating that measures of diffusivity diffusion tensor MRI are valuable tools for characterizing the tissue abnormalities. In a present study, the result demonstrated the feasibility to differentiate DLB and AD by measuring anterior CFTs.

Longitudinal Diffusion MR Imaging Evaluation in Rabbit White Matter after Cerebral Hemisphere Radiation Exposure

Shen, C.[1,2]·Li, Z.[2]·Chen, T.[2]·Tyan, Y.[1,1]·Weng, J.[2]
[1]Chung Shan Medical University Hospital, Taichung, TAIWAN, [2]Chung Shan Medical University, Taichung, TAIWAN.

Purpose
We used a linear accelerator as the source of radiation to establish an adult rabbit model for single-dose cerebral hemisphere exposure radiation-induced brain injury, and afterward, longitudinally evaluated the changes in white matter (external capsule) on a 1.5T clinical MR scanner by using T2WI and DTI indices. We hoped that this experimental model can be used to evaluate the neuro-toxic adverse effects of irradiation treatment.
Materials & Methods
Five male New Zealand rabbits of one year of age received irradiation of 30 Gy (collimations = 4 cm x 5 cm) to the right hemi-brain with a single highly collimated 6MV photon beam from a Varian CL21EX linear accelerator (Varian, Palo Alto, CA, USA) under anesthesia. Brain MRI examinations were performed before irradiation and at 1st to 48th week postirradiation (totally 12 time points) on a 1.5T MR scanner (Sonata, Siemens, Erlangen, Germany) with double loop array coils. Whole brain coronal T2WI were obtained using TR/TE = 4330/114 ms, resolution = 0.19 x 0.39 x 1.5 mm3, number of slices = 30. Diffusion tensor imaging data were acquired using a multislice, single-shot spin-echo EPI sequence with TR/TE = 2900/128 ms, resolution = 0.78 x 0.78 x 2 mm3, number of slices = 12 (contiguously from the genu of the corpus callosum to the end of the cerebrum). They were obtained using 12 diffusion-encoding directions with b values changing from 0 to 2,000 s/mm2. In data analysis, FA, MD, AD and RD

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

maps were first calculated from DTI data using DSI studio (NTU, Taiwan). Using imageJ (NIH, USA), ROIs were drawn manually on three consecutive slices of the DTI maps and the T2WI. All the results were expressed as mean ± standard error (SE), and the ratios of right (injury)/left (control) were calculated for statistical analysis. Paired t-test was used to detect statistical differences between the pre and the postirradiation time points. A p-value of <0.05 was considered to indicate statistical significance. After 48 week of MRI scans, rabbits were sacrificed for histopathologic evaluation, and stained with H&E and LFB.
Results
Diffusion tensor imaging indices showed a continuing decrease followed by a gradual recovery in the FA R/L ratio during the follow-up time points, and the differences reached statistical significance at the 8th week (p-value = 0.0193) and the 12th week (p-value = 0.0373) postirradiation. The gradual increase was followed by recovery in the RD and the MD R/L ratios and the AD R/L ratio showed a decrease at the 2nd week and the 32nd week postirradiation. On T2WI, there was a continuing, gradual decrease at all the follow-up time points, but the differences did not reach a statistical significance at any of them. One rabbit showed significant radiation-related alterations in irradiated right external capsule with large areas of confluent coagulation necrosis and loss of the myelin sheath in both the H&E and LFB sections.
Conclusion
Our quantitative results suggested the DTI characteristics are more sensitive than T2WI and can reflect pathologic changes in radiation-induced brain white matter injury.

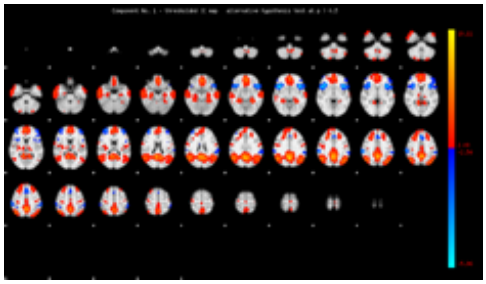
Investigation of the Auricular Acupoint-Cortical Associations Using Resting State Connectivity Functional MR Imaging

Bhatnagar, P.·Firbank, M.·Blee, P.·English, P.·Butteriss, D.·Birchall, D.
Royal Victoria Infirmary
Newcastle upon Tyne, UNITED KINGDOM.

Purpose
Mapping of cortical activation during traditional acupuncture has demonstrated specific and reproducible associations. To date, all fMRI studies have related to traditional acupuncture during active stimulation. Auricular acupuncture is a subtype that is widely used within Eastern traditional medicine, but currently there are no systematic studies of the effects of auricular acupuncture on fMRI, particularly relating to resting state connectivity. The aim of this study was to map the effect of a specific auricular acupuncture paradigm using resting state connectivity fMRI.
Materials & Methods
Ten healthy subjects (age range 25-45 years, with equal males and females) underwent a baseline fMRI (3T scanner). Then they had a session of auricular acupuncture by an acupuncturist specializing in auricular techniques. Three acupoints were treated for 30 minutes on the left ear of each subject in turn: Master Cerebral LM7 (anterior ear lobe), Autonomic Point LM1 (anterior helix) and Shen Men LM16 (antihelix body). This was followed immediately with a further second fMRI scan. Functional data were motion corrected, high pass filtered (0.01 Hz) and smoothed with a 5 mm filter. Independent component analysis (ICA) was performed on all rest runs using FSL-MELODIC package. The set of spatial maps from the group-average analysis was used to generate subject-specific versions of the spatial maps and associated timeseries using dual regression (Beckmann09, Filippini09). For each subject, the group-average set of spatial maps was regressed into the subject's 4D space-time dataset. This resulted in a set of subject-specific timeseries, one per group-level spatial map. Next, the timeseries were regressed into the same 4D dataset, resulting in a set of subject-specific spatial maps, one per group-level spatial map. We then tested for differences within the subjects pre vs postacupuncture using FSL's randomized permutation-testing tool. Comparisons were considered significant at p <0.05 corrected for multiple comparisons using the threshold-free cluster enhancement method.
Results
The independent component analysis identified a number of components similar to previously reported resting networks (e. g., Figure 1). Preliminary analysis showed activation within the lateral temporal lobes, hippocampal formation, subfrontal cortex and prerolandic frontal cortex. Further analyses are underway to identify specific subregional activation, and to map differences pre and postauricular acupuncture. These results will be presented in full.



Conclusion
This study represents the first demonstration of the resting state connectivity fMRI findings associated with a specific auricular acupuncture paradigm. This represents the first step in the comprehensive mapping of auricular acupoint-cortical associations.

Cognitive Impairment in Patients with Idiopathic Generalized Epilepsy: Functional MR Imaging and Diffusion Tensor Imaging Analysis of 20 Cases

Garcia, L. A. L.·Amaro, E.
Hospital das Clínicas da Faculdade de Medicina de São Paulo
Sao Paulo, BRAZIL.

Purpose
Evaluate cognitive impairment in patients with idiopathic generalized epilepsies (IGE) using functional MRI (fMRI) and diffusion tensor image (DTI), comparing healthy volunteers and IGE patients. Idiopathic generalized epilesies are a group of epileptic syndromes composed by juvenile myoclonic epilepsy, typical absence epilepsy, awakening idiopathic generalized epilepsy and nonspecified IGE. Their clinical presentations are characterized by primarily generalized seizures and specific generalized electroencephalographic patterns. These patients tends to control their seizures and have normal cognitive performance and neuroimaging exams.
Materials & Methods
Patients with IGE (20 right-handed patients, 16 women, age range 16 to 50 years, average age 31 years) were compared to healthy volunteers (24 right-handed patients, 13 women, age range 18 to 63 years, average age 32.5 years). Data were acquired usign a 3T scanner (Philips - The Nederlands), with a gradient BOLD echoplanar volumetric sequence, aligned to the ACPC line, matrix 128 x 128, voxel 3 x 3 x 3 mm, with event-related paradigms designed to investigate memory and language, each lasting about 3.5 minutes, with balanced and radomized stimuli, and echoplanar diffusion tensor images, matrix 128 x 128, voxel 2 x 2 x 2 mm, 32 directions, repeated twice. Data analysis was performed by FSL software, with a nonparametric statistical inference approach and motion correction. Comparison among both groups (patients vs controls) was performed with a significance level of $p<0.05$.
Results
Patients with IGE had a significantly worse BOLD activation, mainly at bilateral parietal and occipital (cuneus and precuneus) lobes in response to paradigms sequence when compared to control group. The white matter malfunction showed by Tract-Based Spatial Statistics (TBSS) of DTI data was almost generalized.
Conclusion
Differences among both groups (patients vs controls) to specific cognitive tasks evaluated by fMRI were observed and suggested a less cognitive performance in IGE patients. The impairment of cerebral white matter could imply disconnections between several areas in brain, as a result of prolonged seizures or as a characteristic of the disease.

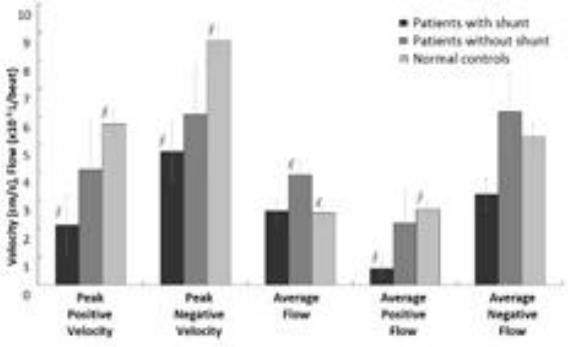
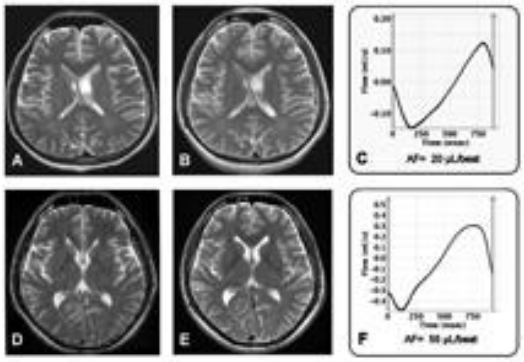
Long-Term Neuropsychologic Sequelae in HIV Seronegative Cryptococcal Meningoencephalitis with and without VP Shunt: A Cine MR Imaging Study

Chen, M.[1]·Lu, C.[1]·Wang, H.[1]·Chen, H.[1]·Tsai, N.[1]·Li, S.[1]·Hsu, N.[2]·Lin, W.[3]·Kung, C.[1]·Lin, W.[1]
[1]Kaohsiung Chang Gung Memorial Hospital, Kaohsiung City, TAIWAN, [2]Yuan's General Hospital, Kaohsiung City, TAIWAN, [3]Chiayi Chang Gung Memorial Hospital, Chiayi County, TAIWAN.

Purpose
Hydrocephalus is common in cryptococcal meningoencephalitis and ventriculo-peritoneal shunt is the management. Cine MRI was applied to evaluate the effect of initial disease severity on long-term CSF flow dynamics and the associated neuropsychologic sequelae in cryptococcal meningoencephalitis patients with and without ventriculo-peritoneal shunt.
Materials & Methods
Eighteen HIV-negative cryptococcal meningoencephalitis patients (10 ventriculo-peritoneal shunt vs. eight without ventriculo-peritoneal shunt) and 32 age- and sex-matched healthy volunteers were included. All subjects underwent complete neurologic examination and neuropsychologic test. Cine MRI was conducted to evaluate CSF flow parameters. Correlations among initial CSF laboratory analysis, imaging findings, present CSF flow parameters, and present neuropsychologic scores were analyzed.
Results
The patients without shunt had higher average flow than controls ($F = 3.516$, $p = 0.038$), suggesting chronic hydrocephalus. The initial higher Evan ratio was associated with higher positive ($r = 0.974$, $p = 0.026$)/negative ($r = 0.983$, $p = 0.017$) peak velocities. Lower CSF glucose level was associated with higher positive ($r = -0.984$, $p = 0.016$)/negative ($r = -0.964$, $p = 0.036$) flow. Worse CSF flow parameters were correlated with poorer performance in attention, picture arrangement, short-term memory, and drawing. The patients with shunt have better results in the block design, orientation, and short-term memory although they had more severe initial presentation.



Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Conclusion
The ventriculo-peritoneal shunts in cryptococcal meningoencephalitis patients do not only save lives but promote long-term cognition function. Cine MRI is useful for unveiling the possibility of chronic hydrocephalus in cryptococcal meningoencephalitis patients that may lead to neuropsychologic deficits.

Natalizumab-Associated Progressive Multifocal Leukoencephalopathy during Multiple Sclerosis Treatment and Consecutive Immune Reconstitution Inflammatory Syndrome: Are There Lessons from Continuous Monitoring of Magnetization Transfer?

Krueger, K. W.[1]·Krueger, P.[2]·Hild, M.[1]·Nowak, A.[1]
[1]Neurologische Gemeinschaftspraxis Hennef, Hennef, GERMANY, [2]University of Geneva, Geneva, SWITZERLAND.

Purpose
Progressive multifocal leukoencephalopathy(PML) can occur as a devastating and potentially lethal complication of long-term administration of natalizumab in patients with multiple sclerosis(MS). There is an urgent need for new diagnostic tools to predict the occurrence of PML and its evolution and course in individual patients. As the magnetization transfer ratio(MTR) can be regarded as a marker for myelin integrity we examined whether continuous monitoring of MTR can contribute towards (i) improved risk assessment of patients with MS under long-term natalizumab and (ii) successful management of PML.
Materials & Methods
We present specific imaging data and results of continuous MTR monitoring in a single 44-year-old female with relapsing-remitting MS(RRMS) during the course of natalizumab-associated PML and subsequent immune reconstitution inflammatory syndrome(IRIS), as well as 19, 13 and 7 months prior to the diagnosis. The patient had received natalizumab for 62 months and was clinically inconspicuous at PML diagnosis. We use a PD-weighted SE sequence for longitudinal registration of MTR in our routine MR protocol for all MS patients: TR = 1710 ms, TE = 30 ms, NSA = 1 before and after an off-resonance MT pulse at 1.5T. Using the FDA-approved software package, NordicICE, consecutive MTR histograms of whole brain, normal-appearing white and gray matter as well as FLAIR- and contrast-enhancing lesions are obtained for subsequent statistical analysis.
Results
Using Kolmogorov-Smirnov and Mann-Whitney tests for equality of distributions, we observed a gradual and significant($p<0.0001$) MTR decrease(leftward shift of the MTR histograms) 19, 13 and 7 months before PML diagnosis both in the future PML lesion and in the whole brain. Relying on ANOVA, we confirmed this result by documenting a significant decrease($p<0.0001$) in average MTR over time. During PML-IRIS the MTR histograms of the specific lesion showed a further and significant($p<0.0001$) MTR decrease and exhibited a bimodal shape. A clear trend towards this unfavorable distribution was apparent at diagnosis when neither clinical signs of PML-IRIS nor gadolinium enhancement were visible. At followup the subsequent gadolinium-enhancing areas of the specific lesion seemed to contribute almost exclusively towards the growing second peak with very low MTR values. Concerning anti-inflammatory prednisolone therapy there was a striking difference in outcome between "core" components of the lesion detected incidentally at diagnosis and those detected later during followup. While the first went straight into apoptosis with cortical skeletonization, the areas from later PML spreading at 11-week followup(being treated relatively "timely") soon showed fading enhancement, almost no apoptosis and a significantly($p<0.0001$) better improvement of MTR at 24-week followup.
Conclusion
Patient-specific databases with consecutive MTR data might enable us to improve the risk assessment of natalizumab therapy in RRMS. In natalizumab-associated PML-IRIS, consecutive MTR monitoring seems to anticipate alarming signs of gadolinium enhancement with its poor prognosis early, and is strongly supportive of a timely and prolonged prednisolone use. Our consecutive MTR results further suggest that there is only a small time window for successful anti-inflammatory therapy of natalizumab-associated PML-IRIS with iv and prolonged oral prednisolone concerning an outcome with little apoptosis and favorable MTR values over time.

Multiplanar Morphometrics of the Optic Chiasm: Feasibility of a Novel MR Imaging Index for Assessing White Matter Atrophy in Multiple Sclerosis

Zaccagna, F.[1]·Matys, T.[1]·Wing, L.[1]·Horsburgh, A.[1]·Antoun, N.[1]·Massoud, T. F.[2]
[1]Addenbrooke's Hospital, Cambridge, UNITED KINGDOM,
[2]University of Cambridge, Cambridge, UNITED KINGDOM.

Purpose
New MRI measurements of brain volume may improve specificity in determining long-term progression of multiple sclerosis (MS). Since sophisticated MRI techniques are laborious, the simple "corpus callosum index" was suggested as a marker for brain atrophy in MS. However, this is limited by inter-subject variations in morphology, including sex differences and handedness. Therefore, in this feasibility study we focused on the optic chiasm (OC). This white matter (WM) structure is related to the optic nerves (ONs), which are known to atrophy in MS, and is readily accessible for measurement on routine brain MRI. We aimed to initially obtain detailed morphometrics in normal and MS patients. We then tested the hypothesis that statistically smaller OCs are present in MS owing to atrophy, aiding in eventual derivation of a simple and potentially clinically useful "optic chiasm index" for evaluation of WM atrophy in MS patients.
Materials & Methods
We retrospectively evaluated standard brain MRIs of 100 patients, 50 with unspecified MS histories, and 50 with normal findings. An observer blinded to clinical data electronically measured eight OC morphometrics on axial T2WIs: its width, A/P diameter, diameters of each ON and optic tract (OT), and angles between individual ONs and OTs. The OC height was measured on midsagittal T1WIs. We also measured the Evans' index to factor for global cerebral atrophy. We expressed continuous values as mean ± SD (min-max; 95% CI). For statistical comparison of clinical characteristics we used an unpaired sample t-test, and for differences in measured parameters between the two cohorts we used the Mann-Whitney test for independent samples (significance set at p-value <0.05).
Results
Three patients were excluded owing to global atrophy. The MS group (M:F=14:34) had a mean age of 36.5 years; the control group (M:F=20:29) had a mean age of 46 years; this age difference was statistically significant. Mean OC width, A/P diameter and height in patients with MS were, respectively, 11.6±0.9 mm (10.3-13.3mm; CI 11.2-12.1), 2.73±0.55mm (2-4mm; CI 2.47-2.98) and 2.18±0.34mm (1.7-3mm; CI 2.03-2.3). In the normal OC group the values were 12.1±1.34mm (10-14.5mm; CI 11.5-12.6), 3.51±0.7mm (2-5mm; CI 3.19-3.83) and 2.3±0.27mm (1.8-3mm; CI 2.2-2.4). There were statistically significant differences between MS and normal patients for A/P diameter (p=0.001) and height (p=0.003), but not for width (p=0.237). As expected, the ONs were significantly smaller in MS (p=0.001), as were the OTs (p=0.004). Consequent to OC atrophy, the angle between each ON was significantly wider (p=0.011) in MS, but not between each OT.
Conclusion
The anterior visual pathway may offer a compelling model for evaluation of demyelinating disease elsewhere in the CNS. The OC is significantly atrophic when examined in a mixed cohort of MS patients. We plan to mathematically derive a clinically useful "optic chiasm index" upon further analysis of stratified and larger MS patient groups. Future studies also will address whether correlation with quantitative MRI of the OC (e.g., using DTI and MTR) can predict future disability in a clinically useful fashion.

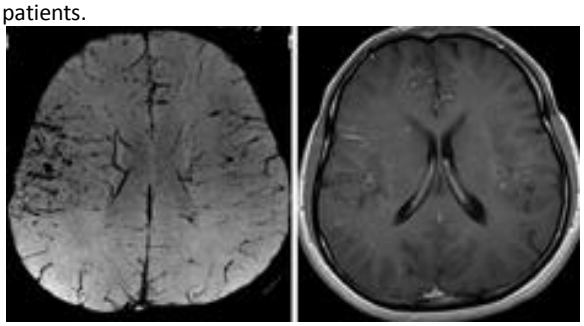
MR Imaging Evaluation in Patients of Primary Central Nervous System Vasculitis of Indian Origin

Garg, A.·Goyal, V.·Gaikwad, S.·Mishra, N. K.·Bhatia, R.·Shukla, G.·Sharma, M. C.
All India Institute of Medical Sciences
New Delhi, INDIA.

Purpose
To evaluate MR imaging findings in patients of primary central nervous system vasculitis (PCNSV) of Indian origin.
Materials & Methods
Between January 2007 and November 2012, 30 patients (M: F=25:5) suspected of having primary CNS vasculitis based on multiple intracranial hemorrhages and punctate-linear enhancement on MR imaging were included in this study. Patients with secondary vasculitis/reversible vasoconstriction syndrome were excluded from the study.
Results
In 30 patients (male: 25, female: 5) the median age at diagnosis was 28 years (range 15 to 48 years); 47% of patients were in the third decade. Seizure (62%) was most common presenting complaint followed by focal neurologic deficits (50%) and headache (42%). Of 18 biopsies done in 16 patients,10 biopsies were positive (granulomatous vasculitis - eight, lymphocytic vasculitis - two). The rest of the 20 patients were diagnosed as PCNSV based on findings on multiple hemorrhages and enhancement characteristics along with negative vasculitis workup. In brain MRI, most common finding was diffuse discrete to confluent WM lesions in both supra and infratentorial compartments. Lesions in bilateral MCA vascular territorial distribution were seen in 92.4%, while bilateral cerebellar involvement, especially in PICA territory, was seen in 52.8%. In brainstem, pons was most common site for involvement. Hemorrhages, microhemorrhages and/or macrohemorrhages, were seen in all but one patient. Extent and distribution of hemorrhages was better seen on SWI imaging as

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

compared to routine gradient imaging sequence (GRE*). Time-of-flight/contrast-enhanced MRA of COW, done in 22 patients, did not show any vascular abnormality. Spinal cord imaging, done in 12 patients (with only spinal symptoms - eight patients, brain symptoms but no spinal symptoms - four patients), showed single/multifocal dorsal cord lesions in 10 patients. Peripheral enhancement was seen in 4/10 spinal cord lesions. All patients with symptoms of spinal cord involvement (eight patients) had multiple asymptomatic brain lesions on imaging. IADSA done in 11 patients was noncontributory except psueoaneurysm in left M2 segment in one case of peripheral SAH and venous phase abnormalities in four patients.



Conclusion

Bilateral supratentorial and infratentorial WM lesions with areas of microhemorrhage and/or macrohemorrhages and punctate and linear enhancements may suggest diagnosis of primary CNS vasculitis after excluding secondary vasculitis/RCVS. Concurrent spinal cord involvement, seen in 33% patients (symptomatic or asymptomatic), is significantly higher compared with existing literature. All symptomatic patients with spinal cord involvement should undergo MRI brain. All suspected PCNSV patients on brain MRI should be screened for spinal cord.

Natalizumab-Associated Progressive Multifocal Leukoencephalopathy during Multiple Sclerosis Treatment: Can Consecutive Monitoring of Magnetization Transfer Improve the Individual Risk Assessment?

Krueger, K. W.[1]·Krueger, P.[2]·Hild, M.[1]·Nowak, A.[1]
[1]Neurologische Gemeinschaftspraxis Hennef, Hennef, GERMANY, [2]University of Geneva, Geneva, SWITZERLAND.

Purpose

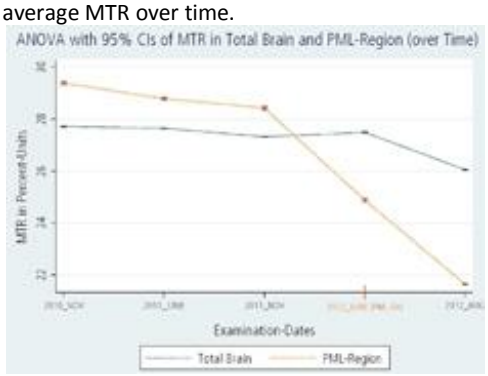
Progressive multifocal leukoencephalopathy(PML) can occur as a devastating and potentially lethal complication of long-term administration of natalizumab in patients with multiple sclerosis(MS). There is an urgent need for new diagnostic tools to predict the occurrence of PML and its evolution and course in individual patients. As, within limits, the magnetization transfer ratio(MTR) can be regarded as a marker for myelin integrity, we examined whether continuous monitoring of MTR can contribute towards an improved risk assessment of patients with MS under long-term natalizumab.

Materials & Methods

We present specific results of continuous MTR monitoring in a single 44 year-old female patient with relapsing-remitting MS and natalizumab-associated PML 19, 13 and 6 months prior to and at the incidental diagnosis of PML. The patient had received natalizumab for 62 months and was clinically completely inconspicuous at diagnosis. We used a PD-weighted SE sequence for longitudinal registration of MTR: TR=1710 ms, TE=30 ms, NSA=1 before and after an off-resonance MT pulse at 1.5T. After manual and software-assisted coregistration, consecutive MTR histograms were obtained retrospectively for the specific PML-suspicious lesion as well as for the whole brain using the FDA-approved software package NordicICE.

Results

Using Kolmogorov-Smirnov and Mann-Whitney Tests for equality of distributions, we found a significant and consecutive decrease of the MTR($p<0.0001$) between all examinations in the voxel of the future PML region. Furthermore a less pronounced but significant decrease ($p<0.0001$) of MTR in total brain voxel could be shown when starting from the baseline examination 19 months prior to diagnosis. Relying on ANOVA, we confirmed these results by documenting a significant decrease($p<0.0001$) in average MTR over time.



Conclusion

Longitudinal MTR databases can be created for individual patients under identical examination parameters with reasonable effort, and the technique seems suitable for routine MRI scan procedures. In our completely inconspicuous RRMS patient a MTR decrease preceded MRI manifestation, and finally, clinical manifestation of natalizumab-associated PML by several months. Given the known insidious beginnings of PML and our lack of reliable markers for an early diagnosis, we suspect that a continuous and significant decrease of total brain MTR may be an early red flag for upcoming PML. It should prompt cessation of natalizumab therapy and lead to further diagnostic steps to exclude imminent PML. Hence, longitudinal MTR monitoring seems well suited for an improved risk assessment of MS patients under long-term

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

natalizumab, but further analysis of larger longitudinal datasets must validate these preliminary results.

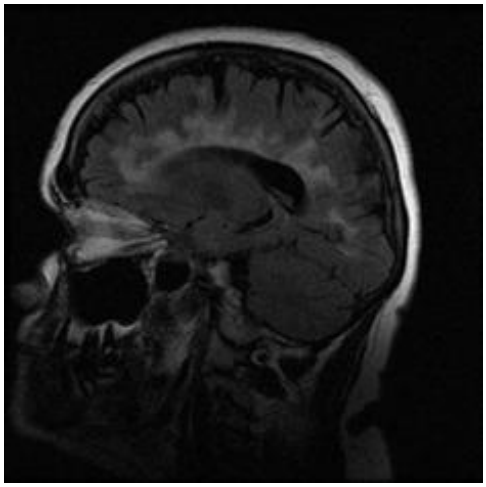
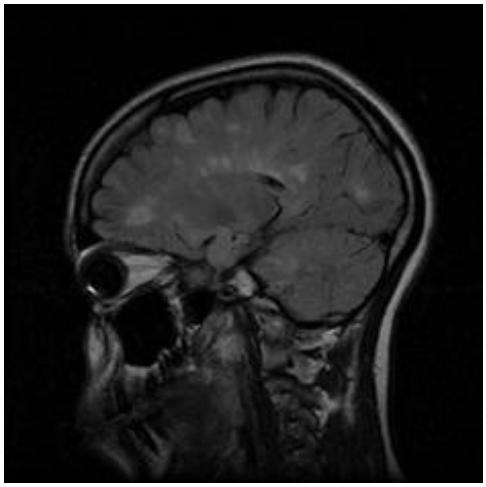
MR Imaging Appearance of Multiple Sclerosis Correlated to CSF, Age, and Clinical Exam Findings

O'Dell, M. C.·Harshman, B.
Florida Hospital
Orlando, FL.

Purpose
Multiple sclerosis(MS) is the most common demyelinating disease and has an extremely variable course, often making early diagnosis difficult. The purpose of this exhibit is to review how MRI appearances correlate to cerebrospinal fluid(CSF) results and physical exam findings in patients with MS among all age groups.
Materials & Methods
We performed a retrospective review of patients who underwent contrast-enhanced MRI of the brain that suggested a demyelinating process or where MS was considered from clinical exam findings. Search included scans from 1.5T and 3T units. Our sample size was 1004 patients, ages 2-92, 754 females, 250 males. The electronic medical record was reviewed for final diagnosis, CSF results (oligoclonal bands, IgG levels), overall MR lesion burden and location (laterality, infra vs. supratentorial, central vs. peripheral), and clinical findings (medical history and neurologic exam).
Results
Pediatric patients diagnosed with MS revealed oligoclonal bands in the CSF with nearly 100% specificity and sensitivity. Almost all presented with leg or facial weakness and a high percentage had both supra and infratentorial involvement. Lesion burden nearly universally increased over time mostly in the supratentorial space. Patients older than 55 years typically had more confluent and extensive supratentorial white matter changes than those with more common degenerative white matter processes such as diabetes or hypertension. Symptoms were more generalized and often overlapped with chronic processes (ischemia, infarcts). The small number of older patients with infratentorial lesions suggests higher morbidity and/or mortality than those with infratentorial involvement.



64 yo with advanced plaque burden, no infratentorial involvement



19 yo with advanced plaque burden with both supra- and infratentorial involvement
Conclusion
Multiple sclerosis has a variable course with multiple factors contributing to the typical MR appearance. Our exhibit reviews how the typical MR appearance correlates to CSF results and physical exam findings in patients with MS.

KEYWORDS: Multiple sclerosis, Multiple sclerosis plaques

Feasibility of T1 Rho Mapping of Intracranial Tumors and Tumor-Related Edema

Villanueva-Meyer, J.[1]·Barajas, R.[1]·Cha, S.[1]·Chen, W.[2]·Shankaranarayanan, A.[2]·Koon, P.[2]
[1]University of California San Francisco, San Francisco, CA,
[2]GE Global Applied Science Lab, Menlo Park, CA.

Purpose
Edema related to intracranial brain tumors is an important cause of morbidity and reflects heterogeneous

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

pathophysiology of underlying tumor. More accurate and quantitative assessment of tumor-related edema may allow preoperative diagnosis of histologic subtype of brain tumor and differentiation between vasogenic and infiltrative edema associated with nonglial and glial tumors, respectively. The purpose of this study was to evaluate the use of quantitative T1rho mapping to differentiate different types of tumor related edema.
Materials & Methods
Our study patient group included nine patients with glioma grade I-III, five patients with glioblastoma multiforme (GBM), three patients with metastases, two patients with meningioma, and five normal subjects. All preoperative MRI examinations including 3D T1rho were performed on a 3T scanner. Three-dimensional T1rho imaging parameters were: 0.9 x 0.9 x 1.6 mm resolution, 280 x 196 mm FOV, 120 slices, 0.5 NEX, 2X ARC parallel imaging along phase encoding direction. Six acquisitions were acquired for T1rho quantification. For T1rho, spin-lock frequency was 500Hz, Time of Spin Lock (TSLs) = 2,10, 40, 60, 80, 100 ms and total acquisition time of 3.5 min. T1rho values in regions of contrast enhancement, peritumoral white matter T2 abnormality, and unaffected white matter were obtained. Additionally, T1rho values in different regions of white matter were recorded in healthy volunteers.
Results
T1rho values in vasogenic edema associated with metastasis or meningioma were statistically higher than infiltrative edema related to GBM (199.78 $\pm$ 31.87 versus 133.62 $\pm$ 24.51 with P = 0.01). However, T1rho values amongst grade I-III gliomas, GBM, and metastasis/meningioma were not statistically significant (138.31 $\pm$ 25.0 versus 128.1 $\pm$ 24.47 versus 113.47 $\pm$ 27.94 with P = 0.27).

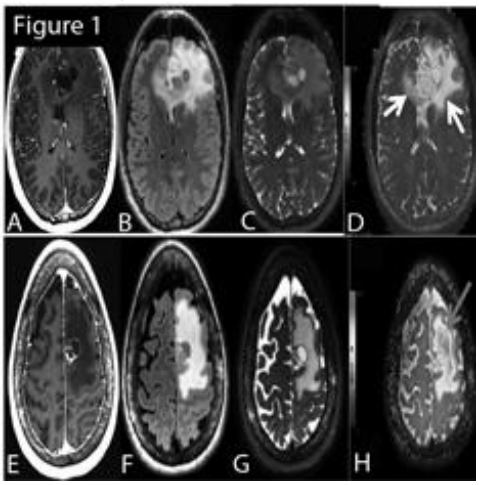

Figure. Diffuse glioma grade III (A-D) and metastatic brain cancer (E-H). (A,E) postcontrast T1-SPGR; (B,F) FLAIR; (C,G) T2-FSE, (D,H) T1rho maps. Vasogenic edema in metastatic cancer shows higher T1rho values in the range of 200-350 msec (gray arrow) than those of invasive edema in diffuse glioma (white arrows).

Conclusion
Our preliminary study demonstrates the feasibility and potential role of 3D T1rho imaging in quantitative assessment of edema related to intracranial tumors. Quantitative T1rho values were significantly different between vasogenic edema and infiltrative edema associated with metastasis and gliomas, respectively. Direct correlation between T1rho values and tissue based on image-guided biopsy is needed for histopathologic validation.

Intrinsic Enhancement from the Necrotic Component of Ring-Enhancing Lesions: A Key Imaging Feature to Distinguish Necrotic Tumors from Abscesses

Wilner, A.·Zagzag, D.·Knopp, E.·Narayana, A.·Parker, E.·Golfinos, J.·Fatterpekar, G.
New York University Langone Medical Center
New York, NY.

Purpose
Diffusion-weighted imaging (DWI) is the imaging sequence of choice to differentiate necrotic tumors from abscesses. However, intralesional hemorrhage and diffusion restriction in certain metastatic lesions can limit utility of DWI. The purpose of our study was to evaluate enhancement characteristics from within the necrotic component of these lesions to distinguish tumors from abscesses.
Materials & Methods
A retrospective study evaluating 50 centrally necrotic, peripherally enhancing lesions, including 41 necrotic tumors and nine abscesses was performed. These lesions were evaluated for ADC value and intrinsic enhancement characteristics from the necrotic component of these lesions.
Results
Apparent diffusion coefficient (ADC) from 7/41 necrotic tumors could not be evaluated due to hemorrhage. The remaining 34 tumors demonstrated mean ADC of 2.45 + 0.16 x 10-3mm2s-1. Of these, two patients with metastatic adenocarcinoma demonstrated restricted diffusion with mean ADC 0.94 + 0.16 mm2s-1. Among the abscesses, three of nine patients demonstrated hemorrhage. The remaining six abscesses demonstrated mean ADC of 0.71 + 0.15 x 10-3mm2s-1. Based on the t-test, a statistically significant difference ($p<0.001$) in ADC values could be demonstrated between necrotic tumors and abscesses. However, presence of hemorrhage in seven tumors and three abscesses, and restricted diffusion in two metastases limited the role of ADC evaluation in 12/50 cases. In terms of enhancement characteristics, all tumors demonstrated intrinsic linear-nodular enhancing septations, presumed regressing vessels from central necrotic component. Only one of nine abscesses demonstrated such intrinsic

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

enhancing septations. Based on ROC analysis, intrinsic enhancement from the necrotic component of tumor was found to be more sensitive than ADC to distinguish abscesses from necrotic tumors.
Conclusion
Intrinsic linear-nodular enhancement from necrotic component of the tumor is more sensitive than ADC to distinguish abscesses from tumors. According to our literature search, this is the first article which mentions the role of intrinsic enhancement as a key imaging feature to distinguish necrotic tumors from abscesses.

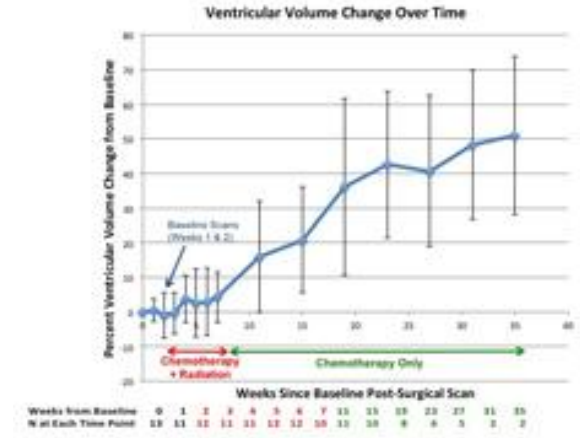
Neuroimaging Markers of Treatment-Associated Neurotoxicity in Glioblastoma Patients Undergoing Brain Radiation and Temozolomide Chemotherapy

Prust, M. J.[1]·Kalpathy-Cramer, J.[2]·Poloskova, P.[2]·Jarafi-Khouzani, K.[2]·Gerstner, E. R.[2,3]·Dietrich, J.[3]
[1]Harvard Medical School, Boston, MA, [2]Martinos Center for Biomedical Imaging, Massachusetts General Hospital, Harvard Medical School, Boston, MA, [3]Stephen E. and Catherine Pappas Center for Neuro-Oncology, Massachusetts General Hospital, Boston, MA.

Purpose
Systemic chemotherapy and brain irradiation are associated with neurocognitive impairment in cancer patients during and after treatment. Up to 70% of cancer survivors experience higher-order cognitive deficits and difficulty performing at pretreatment levels in their personal and professional lives. Prior work suggests that injury to neural stem cells (NSC) and progenitor cells in the hippocampal dentate gyrus and the subventricular zone may play a role in the pathogenesis of chronic neurologic deficits in cancer survivors. Investigation into the effects of treatment on healthy brain tissue is needed to identify markers of potential neurotoxicity and guide future efforts at neuroprotection. Here, we used structural MRI to explore patterns of neurotoxic injury in NSC-associated brain regions within a cohort of glioblastoma patients undergoing chemotherapy and radiation.
Materials & Methods
We longitudinally examined volumetric parameters within germinal zones and nontumor regions in 14 GBM patients receiving daily temozolomide (TMZ) chemotherapy and brain irradiation for six weeks, followed by monthly TMZ. In an IRB-approved study, patients underwent weekly MRI during chemoradiation and monthly thereafter up to six months. Using high-resolution MEMPRAGE images, we constructed regions of interest (ROIs) within the lateral ventricles and hippocampus on patients' baseline images and used nonrigid coregistration to map these ROIs onto subsequent images collected across the treatment period. Ventricular volumetric analysis was restricted to the anterior aspects of the lateral ventricles, a region of low tumor burden within our sample to avoid confounding by resolving tumor pressure during treatment. Hippocampal volumetric analysis was conducted within the hemisphere of lowest tumor burden.
Results
Subjects remaining in treatment beyond the six-week chemoradiation period (N=12) showed mean ventricular dilatation of 39.0% (SD: 22.0%; range: 6.8-67.1%) at final study visit (see Figure 1 for sample sizes at each time point). Percent volume change was not associated with tumor volume changes. We found no significant hippocampal volume changes.



Conclusion
We present evidence of treatment-associated, nontumor anatomical brain changes in patients receiving chemotherapy and irradiation. While preliminary, these data highlight the need for further exploration of treatment-associated brain changes and their underlying pathophysiologic mechanisms. Specifically, patient attrition within our sample and lack of comparison subjects leaves uncertain whether early exposure to chemoradiation initiates an ongoing neurodegenerative process, or whether phenotype severity depends on sustained exposure to chemotherapy over many months. Additionally, future prospective trials employing sensitive neuropsychologic measures are needed to assess the relationship between treatment-associated brain changes and functional neurocognitive sequelae.

Intracranial Tumor Extravascular Extracellular Space: Is There a Correlation between Apparent Diffusion Coefficient and the Extravascular-Extracellular Volume Fraction in Human Meningioma and Cerebral Lymphoma?

Huhdanpaa, H.[1]·Hwang, D. H.[1]·Muradyan, N.[2]·Cen, S.[1]·Torres, F.[1]·Lerner, A.[1]·Commins, D. L.[1]·Rajamohan, A.[1]·Go, J. L.[1]·Law, M.[1]·Shiroishi, M. S.[1]
[1]Keck School of Medicine, University of Southern California, Los Angeles, CA, [2]iCAD, Inc, Nashua, NH.

Purpose
The apparent diffusion coefficient (ADC) determined from diffusion MR imaging can give an impression of the extravascular-extracellular space (EES) and has been shown to be inversely correlated with tumor cell density. The extravascular-extracellular volume fraction (v_e) derived from dynamic contrast-enhanced (DCE) MRI is theorized to provide an estimate of the size of a tumor's EES. Therefore, by logical extension, a positive correlation should be observed between ADC and v_e. The purpose of this study was to determine if there may be a correlation between ADC and v_e as well as with other DCE metrics such as the blood-brain barrier transfer constant (K^{trans}), K_{ep} (K^{trans}/v_e), fractional plasma volume (v_p) and the initial area under the contrast agent concentration-time curve (iAUC) in cerebral lymphomas and meningiomas.
Materials & Methods
Four cerebral lymphomas and five meningiomas were evaluated retrospectively. Diffusion tensor imaging and DCE images were acquired during the same MRI exam. Dynamic contrast-enhanced MR images were postprocessed on an iCAD workstation, a semiautomated image analysis suite. Metrics extracted from DCE MRI were: v_e, v_p, K^{trans}, K_{ep}, and iAUC. Apparent diffusion coefficient maps were extracted automatically from diffusion imaging by the clinical MR scanner software. Dynamic contrast-enhamced and diffusion images were c-registered in SPM to the SPGR using T1 maps and EPI scans. Apparent diffusion doefficient values were interpolated using a concatenated transform into DCE space. Regions of interest were drawn in DCE coordinates on a single slice for the purposes of this study. Voxel-wise correlation pattern between ADC and DCE parameters were examined using scatter plots and tested by random effect model (SAS HPMIXED-High Performance Mixed Model) incorporating both within and between subject variations. Mean and median were extracted for patient level analysis using Spearman correlation.
Results
There was no statistically significant correlation from voxel-wise analysis using random effect modeling. The correlation coefficient between ADC and v_e, K^{trans}, iAUC, K_{ep}, v_e, v_p are -0.01, 0.05, -0.01, 0.05, -0.01, -0.03 respectively. No statistical significance was found in patient level analysis for both mean and median values. The strongest correlation coefficient found was 0.38 between median ADC and median v_e with p=0.32.
Conclusion
Preliminary results showed no correlation between ADC and v_e or any other DCE MRI metrics in meningioma or lymphomas using either mean/median or voxel-by-voxel data. This is in agreement with the only known published study in intracranial tumors by Mills et al. in glioblastomas which also found no correlation between ADC and v_e. This suggests that though ADC and v_e are thought to reflect the size of the EES, our current understanding of these metrics is incomplete. Similarly, no relationship appears to exist between ADC and the other DCE metrics. However, methodologic limitations could be important confounders.

Imaging Features of a Gelatin-Thrombin Matrix Hemostatic Agent in the Intracranial Surgical Bed: A Unique Space-Occupying Pseudomass

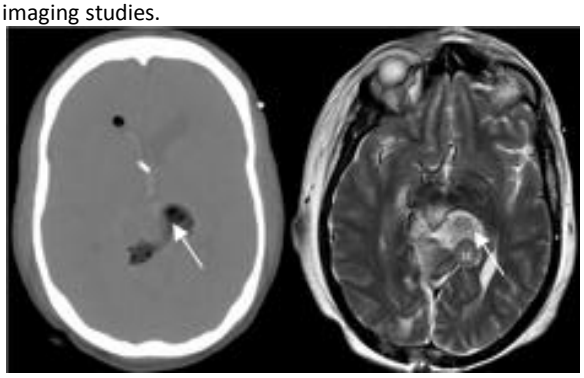
Hyder, I. Z.·Learned, K. O.·Bagley, L. J.·Dolinskas, C. A.·Han, S. S.·Lee, J. Y.
University of Pennsylvania Health System
Philadelphia, PA.

Purpose
Hemostatic agents are used frequently in neurosurgical procedures due to the particular importance of adequate intracranial hemostasis. Gelatin-thrombin matrix (FloSeal Matrix; Baxter Healthcare Corporation, Fremont, CA, U.S.A.) is an absorbable bovine gelatin-human thrombin composite. Its advantages include fast preparation, easy delivery with syringe applicator to various surgical beds, hydrophilic matrix allowing effective adherence to wet surgical field, and effectiveness in coagulopathic disorders. Even though its intracranial neurosurgical application is well published, its unique postoperative radiographic imaging appearance has been scarcely described and potentially can be mistaken for retained foreign body, abscess and/or neoplasm. The immediate postoperative CT and MR imaging appearance and evolution with time of gelatin-thrombin matrix in the intracranial operative beds are investigated.
Materials & Methods
The postoperative CT and MR imaging studies of four consecutive patients (one man, three women, mean age 54 years) who underwent surgical resection of hemorrhagic brain metastases and were treated intraoperatively with FloSeal for hemostasis were reviewed retrospectively (September 2011- December 2012). The surgical beds were evaluated for size, internal architecture, CT attenuation, MR signal intensity and enhancement during the immediate postoperative period (within 48 hours of surgery) and at subsequent followup (within one week to ten months). Imaging findings were correlated with surgical technique and clinical followup.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Results

During the immediate postoperative period, FloSeal within all operative beds appeared as space-occupying material with hypoattenuation similar to (or lower than) fat on CT imaging and distinctive T2-hypointense speckles in a background of T2 hyperintensity. Within one week, all operative beds appeared to be filled with fluid density material (on CT), and the T2-hypointense speckles noted on MRI resolved. By 4-6 weeks, the initial T1 hypointensity changed to T1 hyperintensity, and the sizes of the surgical cavities decreased only 20-30% in all cases. Two patients with longer followup demonstrated complete surgical bed collapse by six months. FloSeal within the operative cavities demonstrated T2 and FLAIR hyperintensity, facilitated diffusion and lack of enhancement on all MR imaging studies.



Conclusion

Gelatin-thrombin matrix FloSeal has distinctive fat-like hypoattenuation on CT and T2 hypointense speckles on MR in the intracranial surgical beds during the immediate postoperative period. FloSeal with its unique space-occupying appearance should not be mistaken for retained nonabsorbable surgical material, abscess, hematoma or neoplasm.

Apparent Diffusion Coefficient and Fractional Anisotropy Values of the Lateral Ventricles and Corpus Callosum in Patients with Leptomeningeal Metastatic Disease

Liu, H.[1]·Wang, J.[2]·Suki, D.[2]·Guha-Thakurta, N.[2]·Chi, T. L.[2]·Ketonen, L. M.[2]·Mayer, R. R.[3]·Weinberg, J. S.[2]·Debnam, J. M.[2]
[1]University of Texas Health Science Center at Houston, Houston, TX, [2]University of Texas M. D. Anderson Cancer Center, Houston, TX, [3]Baylor College of Medicine, Houston, TX.

Purpose

Leptomeningeal disease (LMD) is the dissemination of cancer cells throughout the subarachnoid space, diagnosed by imaging or cerebrospinal fluid (CSF) analysis. On MRI, the magnitude of fluid diffusion within the voxel is measured by the apparent diffusion coeffecient (ADC). A low ADC value indicates that molecular movement in the sampled tissue is restricted, while a high value for ADC indicates that the tissue has free diffusion. The purpose of this study was to evaluate the ADC values of intraventricular CSF and of the corpus callosum, with the hypothesis being that the ADC values will differ between the patients with LMD and controls.

Materials & Methods

The ADC values were measured in 47 patients with LMD confirmed by cytological evaluation of the cerebrospinal fluid, and for control in 40 patients with a history of cancer, but no clinical or radiologic evidence of LMD. Measurements were taken in the atrium of the lateral ventricles, as well as the genu and splenium of corpus callosum in both groups and compared. The Kruskal-Wallis test was used for the statistical analysis.

Results

The mean ADC value in the right and left lateral ventricle in the patients with LMD were 3.20E-09 and 3.24E-09, respectively, compared to 3.04E-09 and 3.03E-09 in the control group (p= 0.016 and 0.002, respectively). No significant difference in ADC values was noted between LMD and control groups for measurements obtained in the genu and splenium of the corpus callosum.

Conclusion

The ADC values in patients with LMD are significantly different than in the control group without LMD, while ADC values in the corpus callosum are not significantly different. Future applications in patients with LMD may include ADC measurement in the lateral ventricles to assess treatment response.

Susceptibility-Weighted Imaging Characteristics of Brain Metastases

Marquez, J. C.[1,2,3]·Medina, F. J.[1,4]·Castillo, M.[1]
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]Resonancia Magnética del Country, Bogotá, COLOMBIA, [3]Pontificia Universidad Javeriana - Hospital Universitario San Ignacio, Bogotá, COLOMBIA, [4]Fundación Valle de Lili, Cali, COLOMBIA.

Purpose

Hemorrhagic brain metastases are not infrequently encountered using only conventional MRI sequences. We utilized SWI in brain metastases to determine the incidence of hemorrhage in them and the effect of treatment type on presence of blood.

Materials & Methods

We retrospectively reviewed SWI in 635 brain metastases in 81 patients. Four hundred eleven metastases had undergone treatment (radiosurgery, gamma knife,

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

radiotherapy, chemotherapy). In order of frequency, primary tumors were nonsmall cell lung cancer (N = 318), breast (N = 95), ovary (N = 50), melanoma (N = 2), sinonasal undifferentiated carcinoma (N = 30), renal cell carcinoma (N = 25), endometrial carcinoma (N = 21), colon cancer (N = 15), small cell carcinoma (N = 13), pancreas (N = 12), pharynx squamous cell carcinoma (N = 8), adrenal cancer (N = 5), thyroid cancer (N = 3), and mixed germ cell testicular tumor (N = 1). The SWI lesions were evaluated by two radiologists and hypointensities representing hemorrhage were recorded as present or absent. Hemorrhage was correlated with presence or not of treatment and its type. Each lesion was measured in two dimensions on the axial plane.

Results

Of the 635 brain lesions evaluated 56.45% showed hemorrhage on SWI. Most of the treated lesions demonstrated blooming, and bigger lesions tend to show more hemorrhage than smaller lesions. Of lesions 10 mm or more in size, 82.3% (163/198) showed hemorrhage and those 15 mm or more in size, 93.9% (77/82) had hemorrhage. In contrast, only 40.6% (101/249) of lesions measuring 5 mm or less showed hemorrhage. Metastases from colon (100%), melanoma (84.4%), and renal cell cancer (92%) showed the higher rates of hemorrhage. Eighty-six percent of metastases treated with radiosurgery alone showed hemorrhage and 82% of those treated with combined radiosurgery and radiotherapy showed hemorrhage. In contrast, 39% of lesions treated with chemotherapy alone showed hemorrhage and 63% and 60% of those treated with radiotherapy alone combined radiation therapy and chemotherapy respectively showed hemorrhage.

Conclusion

Overall more than one-half of brain metastases contained hemorrhage, particularly larger ones. Metastases from melanoma, kidney, and colon were more likely to bleed. The incidence of hemorrhage after treatment ranged from 39-86% being more common in those receiving radiosurgery.

P-41

Role of Dynamic Susceptibility Contrast Perfusion MR Imaging in Selecting Patients with Meningiomas for Preoperative Embolization

Toh, C.·Wei, K.·Peng, Y.·Wong, H.·Ng, S.·Chen, Y.·Wu, Y.
Chang Gung Memorial Hospital
Linkou, TAIWAN.

Purpose

Preoperative embolization is considered a useful adjuvant therapy in meningiomas as it may reduce intraoperative blood loss during subsequent tumor resection. It typically is performed on meningiomas with increased angiographic tumor vascularity and feeders arising from ECA branches. The relationship between relative CBV derived from DSC perfusion and angiographic vascularity on DSA of meningiomas has never been investigated. We aimed to differentiate meningiomas of different angiographic vascularity by using DSC perfusion MRI.

Materials & Methods

Relative CBV were measured in enhancing tumor portions and contralateral NAWM of 32 meningiomas. The CBV ratios were calculated by dividing the tumor values to those obtained from contralateral NAWM. The angiographic vascularity of meningioma was graded as follows: 0 indicated none; 1, minimal; 2, moderate; and 3, exuberant. Embolization would not be necessary for meningiomas with grade 0 or 1 vascularity. Spearman correlations were used to investigate associations between CBV ratios and angiographic vascularity grades. Comparisons of CBV between meningiomas with low (grades 1 and 2) and high (grades 3 and 4) angiographic vascularity were done by using a two-sample t test. The diagnostic performance of DSC perfusion MRI in differentiating meningiomas with low vascularity from those with high vascularity was assessed with ROC curve analysis.

Results

There were no correlations between angiographic vascularity and the size or location of meningiomas. Statistically significant correlations were observed between angiographic vascularity grades and CBV ($r = 0.867$; $P < .001$). The CBV of meningiomas with low vascularity ($5.59 \pm .01$) were significantly ($P < .001$) lower than those of high vascularity (14.97 ± 7.73). In differentiating between meningiomas of low and high vascularity, the diagnostic performance of CBV, in terms of AUC, was 0.927.

Conclusion

Dynamic susceptibility contrast perfusion MRI can differentiate meningiomas of different angiographic vascularity. Dynamic susceptibility contrast perfusion MRI can serve as a noninvasive tool to evaluate the vascularity of meningiomas prior to catheter angiography, and aid in selecting patients for preoperative embolization.

Using Image-Based Statistical Probes to Query Imaging Archives

You, K.·Butman, J. A.
The Clinical Center of the National Institutes of Health
Bethesda, MD.

Purpose

Querying image databases for certain image features typically requires that an observer has coded or classified the images in some manner. This is a time-consuming process requiring an expert reader. Therefore, most image

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

databases (e.g., those on hospital PACS systems) have not been coded in such a manner. Our goal was to generate a probe capable of identifying studies in a brain tumor image database that contained nonartifactual sites of diffusion restriction, thereby streamlining data collection for future analysis.

Materials & Methods

Isotropic diffusion-weighted image (DWI) datasets (n = 7354) obtained on all brain tumor patients (n = 1074) were automatically transferred to an archive, registered into a patient-specific space and stored in Analyze format. To develop a probe of this dataset, an arbitrary sample of 50 DWI data volumes was selected. Signal intensities were normalized (median) and the volumes were affine registered to a base image using nine degrees of freedom. From this data, the probe generated the voxel-wise mean and z-scores at each voxel (in a manner analogous to fMRI analysis). Next, each individual DWI was tested against the probe, and the number of voxels exceeding various z-score thresholds was recorded. Independently, each dataset was classified as DWI positive or negative by an expert. Receiver-operating characteristic curves were generated by varying the the z-score threshold as well as the number of voxels exceeding the threshold. Based on the results of this analysis, criteria were selected and the database was probed.

Results

The probe performed well when compared to the gold standard, with the area under the ROC curves ranging from 0.80 to 0.87 depending on the standard deviation selected. The probe was most effective when counting voxels with standard deviation 3 (area under ROC curve = 0.87) or 4 (area under ROC curve = 0.86) above the mean. When the t-scores were calculated using a mean and standard deviation from a separate sample of 50 diffusion-weighted images, the probe on the initial 50 diffusion-weighted images was similarly effective. The area under the ROC curves ranged from 0.75 to 0.85. However, the probe was less effective when performed on images in which the signal intensity of the signal abnormality was lower and closer to the surrounding voxels. In a probe on a sample of 50 images with this characteristic, the area under the ROC curves ranged from 0.24 to 0.33.

Conclusion

Diffusion abnormalities are characterized by large signal differences between lesion and normal brain in DWI. Identification of studies in which diffusion abnormalities are present in an image archive is feasible with statistical probes. However, because of susceptibility effects, high signal due to signal pileup is found on nearly every image. In order to identify studies in which diffusion abnormalities are present, we developed a statistically based probe that is relatively insensitive to these false positive results. Such probes are necessary to extract data from massive image archives as it is impractical to use expert observers in this role.

P-43

Diffusion Tensor Imaging in Patients with Recurrent Neoplasm versus Treatment Effect

Masch, W. R.[1]·Wang, P.[1]·Chenevert, T. L.[1]·Junck, L. R.[1]·Tsien, C.[1]·Heth, J.[1]·Wang, A.[1]·Sundgren, P. C. M.[2,1]
[1]University of Michigan, Ann Arbor, MI, [2]Lund University, Lund, SWEDEN.

Purpose

The purpose of this study is to retrospectively analyze the diffusion-tensor imaging (DTI) characteristics of new enhancing lesions in patients with brain neoplasms who have undergone radiation therapy and chemotherapy in an attempt to radiologically differentiate recurrent tumor from treatment-related injury.

Materials & Methods

Ten patients with new contrast-enhancing lesions who previously had undergone treatment with surgery, chemotherapy and radiation therapy for a brain neoplasm were examined with diffusion tensor magnetic resonance (MR) imaging. Apparent diffusion coefficients (ADCs), fractional anisotropy (FA) values, and eigenvalues were measured on maps generated from isotropic DW images in the following areas: the enhancing lesion, the perilesional edema, and the contralateral normal-appearing white matter. Magnetic resonance spectroscopy (MRS) data were used in guiding surgical biopsy/resection of the lesions as well as in the placement of the region of interest cursor such that the portion of the enhancing lesion with the most malignant MRS signal was measured. Radiation necrosis versus tumor recurrence was determined by histologic evaluation in nine patients and by clinical course in one patient. Between group differences in ADC, FA, and eigenvalues were compared using a two-sample t-test.

Results

Of the 10 patients enrolled, five had glioblastoma multiforme, four had a glioma, and one had metastatic disease (ages 20-62 years; 1 F/9M). The treatment-related injury group was composed of five patients and the recurrent tumor group was composed of five patients. Apparent diffusion coefficient values in the contrast-enhancing lesions trended higher (P = 0.15) for the recurrence group (mean +/- S.D. = 1.16×10^{-3} +/- 0.24×10^{-3}) in comparison to the treatment-related injury group (mean +/- S.D. = 0.90×10^{-3} +/- 0.27×10^{-3}). The principal eigenvalues ($\lambda\|$) in the contrast-enhancing lesions also trended higher (P = 0.10) for the recurrence group (mean +/- S.D. = 1.42×10^{-3} +/- 0.31×10^{-3}) in comparison to the treatment-related injury group (mean +/ - S.D. = 1.05×10^{-3} +/- 0.31×10^{-3}).

Conclusion

The assessment of DTI characteristics of new contrast-enhancing lesions in patients with previously treated brain neoplasms, particularly evaluation of the ADC and eigenvalues, may be helpful in differentiating recurrent neoplasm from treatment-related injury.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

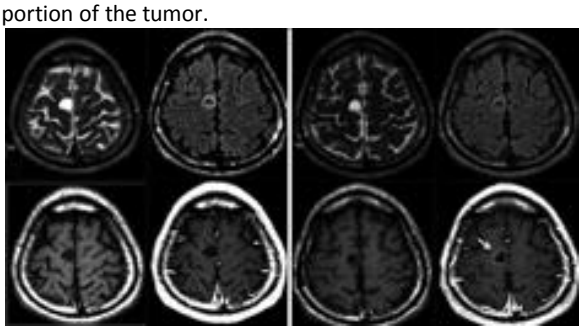
Renovate Enhancement Developed in Low-Grade Glioma Revealed No Malignant Transformation: Imaging and Pathologic Correlation

Kawamura, Y.·Hadeishi, H.·Narita, M.·Hoshi, K.
Kameda Medical Center
Chiba, JAPAN.

Purpose
Transformation from low-grade “diffuse” astrocytoma to high-grade has been accepted as a natural progression. However, in this study authors observed the renovate enhancement in three patients whose previous MRI had shown a lack of enhancement and following operation revealed no histologic malignancy. The mechanism of the altered enhancement of low-grade astrocytoma was discussed.
Materials & Methods
Three patients (age 17, 22 and 25 yeara, one man and two women) known to have well circumscribed nonenhancing brain tumor had been followed up more than three years on MRI with 1.5T and 3T magnet (Signa, GE, USA). T1-weighted images (SE, TR/TE/NEX: 333-483/14-20/2), T2-weighted images (FSE, TR/TE /NEX: 3200-3500/83-100/2), FLAIR images (FSE, TR/TE/TI /NEX: 10002/125/220/1), and EPI diffusion weighted images (TR/TE /NEX: 5000/101/1, *b* = 1000) were obtained. For contrast-enhanced MRI, 0.1 mmol/kg of gadolinium-DTPA was injected intravenously. Enhanced CT was performed with 64-raw-unit (Aquillion 64, Toshiba, Japan) The patient's age, sex, main symptoms, tumor location and follow-up duration are summarized in Table 1. Histopathologic examination was performed with HE staining and immunohistochemical staining such as GFAP, S-100, occludin (ZYMED; vascular endothelial tight junction marker), CD45R0 (DAKO; T cell marker), CD20cy (DAKO; B cell marker), anti-CD31 (DAKO; microvascular density).
Results
Clearly demarcated ovoid lesions were demonstrated as high intensity on T2-weighted and FLAIR images and as homogeneous low intensity on T1-weighted images in case 1 (Figure 1, left). Diffusion-weighted images did not show high intensity in all cases. Well circumscribed ring enhancement (Figure 1, right; arrow) developed on follow-up MRI taken three years later. Punctate enhancement was revealed within (case 2) and adjoining to nonenhancing portion (case 3). Total surgical removal was performed subsequently according to the renovate contrast enhancement seen on MRI. Microscopic examination did not show significant cellular atipia, mitosis, tumor neovascularity and tumor necrosis. In case 1, the immunohistochimical examination confirmed intact vascular endothelial tight junction in enhancing portion of the tumor with infiltration of B-cell lymphocytes and macrophage. In cases 2 and 3, the vascular endothelial tight junction marker (occludin) was negative in contrast to positive staining of occludin in the nonenhancing portion of the tumor.



Conclusion
Our result indicates that the new onset of enhancement in previously nonenhancing low-grade astrocytomas do not necessarily imply the histologic deterioration but could be influenced by the change of vascular endothelial tight junction and/or infiltration of inflammatory cells.

Usefulness of SPACE T2-Weighted Images in Diagnosing Small Pituitary Adenoma: Comparison with Dynamic-Enhanced T1-Weighted Images

Ahn, K.·Choi, H.·Jung, S.·Kim, B.
College of Medicine, The Catholic University of Korea
Seoul, KOREA, REPUBLIC OF.

Purpose
Although dynamic-enhanced T1-weighted images have been accepted as the best imaging technique to detect pituitary microadenoma, frequently there have been difficulties to make correct diagnosis when the imaging findings were vague due to regional susceptibility or insufficient contrast between the lesion and normal gland. Sampling perfection with application optimized contrasts by using different flip angle evolution (SPACE) T2-weighted images are three-dimensional imaging techniques based on fast spin-echo method, thus very thin slice images with compatible signal to noise ratio are possible with allowable scanning time. The purpose of this study is to know the usefulness of SPACE-T2-weighted images in diagnosing small pituitary adenoma, especially for microadenoma.
Materials & Methods
Total 28 patients with small pituitary adenoma (< 2 cm, including 16 microadenomas) who underwent dynamic-enhanced T1-weighted images and SPACE T2-weighted images together were recruited in our study. As controls, 21 patients without any lesion in pituitary gland were included. Two experienced radiologists reviewed both dynamic-enhanced T1-weighted images and SPACE T2-weighted images independently to detect adenoma in the pituitary gland. To score the lesion conspicuity four point

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

scale (0-3) was used and the sensitivity, specificity and diagnostic accuracy of both imaging techniques were evaluated.
Results
No significant difference between average score of dynamic T1-weighted images and SPACE T2-weighted images was noted (1.55 versus 1.43, $p = 0.5$). SPACE T2-weighted images showed similar sensitivity to the dynamic-enhanced T1-weighted images (85.7% 92.9%, respectively) in detecting small pituitary adenoma. The specificity of SPACE T2-weighted images was superior to that of dynamic-enhanced T1-weighted images (100% 95.2%, respectively). On SPACE T2-weighted images the signal intensities of pituitary adenomas were variable (high, low and isointense signal intensities in 14, 11 and 3 cases, respectively).
Conclusion
SPACE T2-weighted images showed similar sensitivity and superior specificity to dynamic-enhanced T1-weighted images in diagnosing small pituitary adenoma. Considering that infusion of MR contrast medium was not used in SPACE T2-weighted images, there are very encouraging results. SPACE T2-weighted images can be used as a very good complementary imaging technique to diagnose small pituitary adenoma in clinically concerned patients.

Evaluation of a Bayesian Expert System for Aiding Neuroradiology Diagnoses: A Pilot Study

Tanwar, M.·Herskovits, E. H.·Nasrallah, I. M.·Kundel, H.·Mohan, S.·Li, C.·Lynch, M. C.·Bryan, R.
University of Pennsylvania
Philadelphia, PA.

Purpose
Recently, there has been an explosive growth of digital imaging data, resulting in challenge and opportunity. Contemporary computational techniques can analyze immense amounts of complex data and are being incorporated into decision-support applications. We have developed a prototypical Bayesian expert system that takes input key features (KFs) detected in images and outputs a differential diagnosis (DDx) ranked by posterior probability. We hypothesize that the idealized KFs upon which the model was based and those extracted by radiologists at different levels of training and the DDx lists produced by the model and human readers are similar.
Materials & Methods
Eleven neuroradiological entities (abscess, cerebritis, craniopharyngioma, glioblastoma, hematoma, infarct, metastasis, multiple sclerosis, rhombencephalitis, toxoplasmosis, xanthogranuloma) and normal, were evaluated by a senior neuroradiologist to identify characteristic and idealized imaging KFs and approximate conditional probabilities of these features. These features and probabilities were used to build a Bayesian expert system for differential diagnosis. Two attending neuroradiologists selected a test set of 60 diagnosis-proven MR examinations from our PACS: 5 for each entity. Three diagnosis-blind readers -- attending neuroradiologist, neuroradiology fellow and PGY-3 radiology resident -- reported the KFs and their rank ordered DDx after reviewing each case. We entered each reader's KFs into our model, obtaining a posterior probability ranked DDx list for each case-reader combination. We compared reader's observed KFs to each other and to the ideal disease features, and we compared readers' DDx to those of the model and to each other. We also compared DDx lists to the clinically proven diagnosis. Percentage agreement, kappa statistics, and ROC analysis were used to evaluate human and computer reader performance.
Results
For individual extracted KFs, there was moderate to excellent agreement between the different human readers (57-91%), which was similar to agreement between individual reader KFs and the idealized KFs for the various diseases (42-94%). Inter-reader agreement for each feature was similar to agreement between readers and the model system KFs. The model, using ideal cases (i.e., cases with "classic" features, as determined by a senior neuroradiologist), was in 100% agreement with the known diagnosis. These indicate that the KFs upon which the model system was based are concordant with actual clinical cases. The primary diagnoses of the human readers versus the proven diagnoses showed percent agreement of 77-92% and K = 0.74-0.91. ROC analysis of DDx for human readers (AUC 0.91-0.93) and model output diagnoses based on human extracted KFs (AUC 0.66-0.82) all demonstrated excellent performance.
Conclusion
A prototype neuroradiological decision-support application was developed and evaluated using a small set of clinical neuroradiological MR examinations. Readers selected similar KF values regardless of experience level, probably reflecting our use of readily noticeable findings. There was excellent agreement between each readers' most likely diagnoses and the known diagnosis, with the resident manifesting slightly lower accuracy, probably because our 12 entities are fairly distinct. Further development might render this software suitable for reducing the variability of radiology reports, improving report quality, and increasing the efficiency of practicing radiologists.

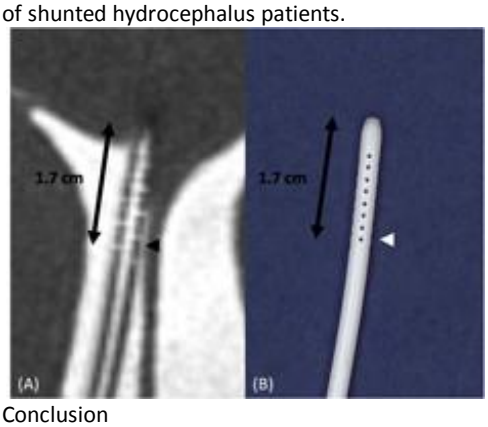
Evaluating Ventriculostomy Catheter Position and Patency Using High-Resolution MR Imaging Techniques

Eckart, D.·Solomon, D.·Moghekar, A.·Rigamonti, D.·Blitz, A.
Johns Hopkins Hospital
Baltimore, MD.

Purpose
We present the result of two years of clinical experience using high-resolution MRI techniques to characterize the position and patency of ventriculostomy tubes during the evaluation of shunted hydrocephalus.
Materials & Methods
Clinical MRI examinations performed at our institution were tailored for evaluation of shunted hydrocephalus, using isotropic high-resolution heavily T2-weighted imaging (CISS) and T1-weighted sequences (VIBE) with and without intravenous gadolinium contrast. After obtaining IRB approval, the MRI examinations of patients with ventriculostomy tubes who had undergone an MRI protocol including high-resolution imaging were reviewed restrospectively by two radiologists. Twenty-one cases met our inclusion criteria. The catheter position and location of the side holes were assessed. The patency of the lumen was evaluated by documenting the presence or absence of internal debris. Additionally, three-dimension reformations were performed to best depict the course and position of the catheter.
Results
Using high-resolution MRI with attention to the ventriculostomy catheter, excellent visualization of side-hole position was observed in 17/21 cases. In seven of 16 cases, debris was visible in the catheter lumen, suggesting obstruction. Three-dimensional MRI reconstructions better depicted the course and position of the ventriculostomy catheters relative to conventional imaging, aiding the neurosurgical service in management of shunted hydrocephalus patients.



Conclusion
Despite the frequency of shunt malfunction and malpositioning, MRI often is not utilized to its full potential to evaluate the position and patency of the proximal ventriculostomy catheter itself. Using high-resolution techniques and multiplanar reformations, sublties of catheter position, side-hole location, and the presence luminal debris (patency) can be assessed with greater sensitivity.

Usefulness of RESOLVE Multi-Shot, Diffusion-Weighted Imaging in Clinical Practice

Ahn, K.·Choi, H.·Jung, S.·Kim, B.
College of Medicine, The Catholic University of Korea
Seoul, KOREA, REPUBLIC OF.

Purpose
Although single-shot echo-planar imaging is well established as the method of choice for clinical diffusion-weighted imaging, it is prone to artifacts due to susceptibility changes at tissue interfaces and has a limited spatial resolution. RESOLVE multi-shot, diffusion-weighted imaging is based upon the readout-segmented EPI method, which has been modified to incorporate 2D navigator phase correction and navigator-based reacquisition. It provides a robust correction for motion-induced phase artifact in allowable scan time. The purpose of our study is to evaluate the usefulness of RESOLVE in detecting small acute infarction in routine practice by comparing image quality and detecting rate between RESOLVE and conventional single-shot diffusion imaging.
Materials & Methods
Twenty healthy volunteers and 39 consecutive patients with total 337 infarct lesions were recruited and underwent RESOLVE and single-shot diffusion imaging. In control group, overall image qualities of both techniques were evaluated qualitatively and compared at level of anterior and middle skull base. In 39 patients with infarctions, the number of small acute infarctions less than 1 cm was counted on two sequences for quantitative comparisons.
Results
On overall image quality comparison, RESOLVE showed significant superior quality to single-shot diffusion imaging ($p < 0.01$). On quantitative comparisons in patients with small acute infarctions, total 294 lesions were detected on single-shot diffusion-weighted imaging. However, with RESOLVE technique 43 additional lesions were detected.
Conclusion
RESOLVE multi-shot, diffusion-weighted imaging for acquiring high-resolution diffusion images showed low susceptibility and T*2 blurring and a robust correction for motion-induced artifact. The technique provides significant image quality improvement compared with single-shot diffusion imaging in detecting small size acute infarction in the brain.

Qualitative Evaluation of Dual-Energy Head CT in Comparison with Conventional Head CT

Hwang, W. D.·Mossa-Basha, M.·Andre, J. B.·Culberton, S.·Ramos, M.·Anzai, Y.
University of Washington
Seattle, WA.

Purpose
1) To determine the optimal monochromatic energy levels for supratentorial brain and posterior fossa, based on blinded-reader analysis. 2) To perform quality analysis of dual-energy CT over conventional polychromatic CT. 3) To quantify the radiation dose of dual-energy CT gemstone spectral imaging (GSI) unenhanced head CT and conventional CT.
Materials & Methods
From July 25 to October 24, 2012, approximately 153 patients were scanned with dual-energy 64-channel MDCT scanner, GE Discovery CT750HD, in GSI mode. Patients with pathology such as MCA territory infarct and posterior fossa tumor were excluded from the study. A total of 20 patients scanned at regular dose GSI and 19 patients scanned at low dose GSI, with recent comparison study (within one year) on the same Discovery scanner in non-GSI mode, were included in the study. Scans were reconstructed at monochromatic viewing levels from 60 to 80 kev, at 2 kev intervals. These along with a recent comparison study (control) were viewed simultaneously for each patient on an independent workstation by a blinded attending neuroradiologist. The reader was asked to grade each energy level and the control study on three parameters, insular cortex differentiation, posterior fossa artifact, and overall study noise, on a scale of 0 to 5, 0 being nondiagnostic, 5 being superior quality.
Results
Overall optimal viewing energy was determined to be 62 kev for regular dose and 72 kev for low dose GSI CT. Posterior fossa image quality was determined to be best at 80 kev at both regular and low dose. No significant reduction in image quality was found with either regular or low dose dual-energy CT over conventional CT. Posterior fossa image quality was found to be superior with both regular and low dose dual-energy CT over conventional CT. Conventional CTs were all scanned at 140 kvp and 330 mA, with a CTDI dose 43.81 +/- 1.61 mGy. Regular dose GSI CTs were scanned at 140 kvp and 630 mA, with a CTDI of 36.74 +/- 1.21 mGy, representing a mean dose reduction of 16% over conventional CT. Low dose GSI CTs were scanned at 140 kvp and 360 mA, with a CTDI of 28.16 +/- 0.88 mGy, representing a mean dose reduction of 36% over conventional CT.
Conclusion
There is a significant dose benefit in performing dual-energy GSI head CT with current reconstruction algorithms at regular or low dose compared with conventional CT. There was no significant degradation in subjective image quality observed in direct comparison of dual-energy with conventional CT. Optimal monochromatic viewing energy was found to be 62 kev for regular dose and 72 kev for low-dose dual-energy CT. There was an improvement in posterior fossa artifact reduction and image quality with GSI. Thus, GSI is a viable alternative to conventional polychromatic unenhanced head CT in the clinical setting.

Assessment of C-Arm Cerebral Blood Volume Maps Obtained through Aortic Arch Injection with 50% and 30% Diluted Contrast Medium

Itokawa, H.·Moriya, M.·Fujimoto, M.·Tomita, Y.·Okamoto, N.·Kikuchi, N.·Shibata, N.·Awane, A.
Kasai Shoikai Hospital
Tokyo, JAPAN.

Purpose
Recent studies have demonstrated the feasibility of C-arm cerebral blood volume (CBV) maps obtained via intravenous contrast injection. For patients undergoing diagnostic angiography or endovascular treatment, intra-arterial injection may provide a viable approach for reducing the amount of contrast medium used during C-arm CBV imaging. The purpose of this study was to assess the feasibility of C-arm CBV maps obtained through aortic arch injection at 50% and 30% diluted contrast medium, and to compare these maps with CT perfusion (CTP) CBV.
Materials & Methods
Twenty-seven patients with normal perfusion on CTP CBV were enrolled in this study. Standard CTP study was performed on a 64-section CT scanner (Aquillion, Toshiba, Japan). For each patient, C-arm CBV images (syngo neuro PBV IR, Siemens AG, Forchheim, Germany) then were acquired via a flat-detector angiographic system (Artis zee BA, Siemens AG, Forchheim, Germany). C-arm CBV requires two rotational acquisitions, the first without contrast injection, and the second with a delay after the start of contrast injection in order to achieve steady state of contrast flow in the brain parenchyma. The delay was timed individually in each patient via a test bolus injection. All studies were performed via aortic arch injection with 4F diagnostic catheter positioned directly above the aortic valve. Depending on the injection delay, 75-100 ml of diluted contrast medium was injected at a rate of 5ml/s. Patients were divided into two groups; Group A (17 patients) for which 50% diluted contrast was used, and Group B (10 patients) for which 30% diluted contrast was used. The acquired data were reconstructed on a separate workstation (syngo XWP VB 15D, Siemens AG, Forchheim, Germany). C-arm CBV and CTP CBV were manually coregistered, and regions of interest (ROIs) subsequently

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

were placed in the anterior cerebral artery (ACA), middle cerebral artery (MCA), posterior cerebral artery (PCA) territories and basal ganglia (BG).
Results
C-arm CBV with aortic arch injection was technically successful, without complications, and image quality was adequate for evaluation in all patients. No significant differentiation of image quality was observed between groups A and B. C-arm CBV values for groups A and B were higher than CTP CBV values (p0.05). C-arm CBV right/left ratios in ACA and MCA were slightly higher than those for CTP CBV; however, these differences did not reach statistical significance (0.01<p<0.05). The same tendency was observed in Group A and Group B. A maximum of 30 ml of contrast was used for C-arm CBV imaging in Group B, compared to 60 ml of contrast for intravenous injection C-arm CBV or CTP CBV.
Conclusion
Preliminary results indicate that aortic-arch injection of 30% diluted contrast medium generates C-arm CBV maps that are comparable to those obtained with 50% diluted contrast medium, with the advantage of lower contrast dosage requirement. C-arm CBV with 30% diluted contrast medium may provide clinically useful information for the patient management.

KEYWORDS: C-arm CT CBV

New Multispectral MR Imaging Technique for White Matter Lesion Detection and Classification

Chen, C. C. C.[1]·Chen, H.[2]·Chai, J.[1]·Lee, S.[1]·Yang, C.[1]·Chang, C.[3]
[1]Taichung Veterans General Hospital, Taichung, TAIWAN, [2]Hungkuang University, Taichung, TAIWAN, [3]University of Maryland, Baltimore County, Baltimore, MD.

Purpose
White matter lesions (WML) commonly are found in elderly subjects and are associated with cognitive decline and dementia. Magnetic resonance imaging (MRI) has become an important imaging modality for understanding and managing several aspects of WML. WML exhibit almost the same hyper-signals in T2-weighted MRI, and hypo-signals in T1-weighted MRI, with respect to normal WM intensities. Many studies measure WML volume using a single MR sequence or combining sequences. Such approaches include probabilistic methods, neural networks, and the expectation-maximization algorithm. These methods demand complex computational efforts to achieve good performance. In this study, we developed a new multispectral approach, called constrained energy minimization (CEM), to overcome these difficulties for a study of WML detection. The CEM has shown great success in hyperspectral target detection and classification. It was designed based on a premise that no background information is required for target detection. The aim of this study is to introduce a new multispectral approach for the validation of WML volumetry.
Materials & Methods
Synthetic data from the BrainWeb database was used to evaluate the accuracy of WMLs volume measurements by using the proposed method to analyze three sets of T1-weighted, T2-weighted and proton density images. The parameter setting includes three noise levels of 0%, 1%, and 3% for brain with lesions. Let **d** be the spectral signature of WML. The goal is to design a finite impulse response (FIR) linear filter specified by an ***L***-dimensional vector $\mathbf{w} = (w_1, w_2, \cdots, w_L)$ that passes the desired signature **d** by constraining its direction while minimizing its output energy that are caused by signal source vectors with directions other than the constrained direction. The value of resulting from CEM method represents the estimated abundance fraction of the object signature **d** contained in the image pixel. As a result, the image generated by the CEM filter is generally gray scale where the gray level value of each image pixel reflects the detected amount of the abundance fraction of the desired object present in the pixel. The object detection then is performed based on the resulting gray scale image and classification is carried out by detecting the desired objects in separate images. In order to conduct a quantitative study and compare with the ground truth, we convert the CEM-generated abundance fractional images to binary images. In this study, the adaptive threshold is used for the cutoff abundance fraction threshold value to convert CEM results to binary images. The Tanimoto index was measured to statistically evaluate the results of the WML volumes with the ground truth data of the synthetic brain images.
Results
The mean TI values of WML in synthetic MR images with noise level 0%, 1%, and 3% were separately 0.88, 0.86, and 0.82. The preliminary results demonstrated the proposed technique would be effective.
Conclusion
Our experimental results revealed significantly high accuracy of the CEM method in classification of synthetic brain WML data. The proposed method could effectively enhance the detection and classification of brain lesions.

Evaluation of Cerebral Perfusion Parameters on CT Perfusion Associated with Global Cerebral Edema in Aneurysmal Subarachnoid Hemorrhage

Fodera, V.·Sanelli, P.·Gupta, A.·Baradaran, H.
New York Presbyterian-Weill Cornell
Colonia, NJ.

Purpose
Aneurysmal subarachnoid hemorrhage (SAH) is a devastating disease with severe complications including

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

global cerebral edema (GCE) contributing to functional and cognitive disability. It is well known that GCE occurring during the early stage (day 0-3) independently leads to poor outcomes. However, little is known about mechanisms underlying the development of GCE and its effects on cerebral perfusion. Our aim was to evaluate cerebral perfusion parameters on CTP associated with GCE in aneurysmal SAH.

Materials & Methods

A retrospective study of consecutive SAH patients with CTP performed on admission (day 0-3) admitted from 2008-2010. Presence of GCE was determined on the noncontrast CT (performed concurrently with CTP) by two independent neuroradiologists blinded to all other clinical and imaging data using Claassen's definition: (1) complete or near-complete effacement of the hemispheric sulci and basal cisterns and (2) bilateral disruption of the hemispheric gray-white matter junction at the level of the centrum semiovale. Global cerebral edema was considered present if there was more than 75% sulcal effacement or more than 75% of gray-white matter disruption. CTP was postprocessed into cerebral blood flow (CBF), cerebral blood volume (CBV) and mean transit time (MTT) data using a standardized method. Qualitative analysis of CTP maps was performed by two independent blinded neuroradiologists to determine presence of global CTP deficits, defined as diffuse reduction in CBF and/or elevated MTT. Adjudication was performed by a third neuroradiologist. Test characteristics of CTP were calculated and statistical significance was determined by Fisher's exact test.

Results

A total of 45 patients were included in the statistical analysis. There were 42.2% (19/45) patients classified as GCE and 57.8% (26/45) as no GCE. Global perfusion deficits were seen in 52% (10/19) patients with GCE and 7.7% (2/26) without GCE. There is a statistically significant difference in the global perfusion in GCE ($p = 0.0014$) manifesting as diffusely reduced CBF and/or elevated MTT. Figure 1 demonstrates a patient with GCE and global perfusion deficit. Global perfusion deficits had a 53% sensitivity, 92% specificity, 83% positive predictive value and 73% negative predictive value.

Conclusion

Global perfusion deficits on CTP were statistically increased in GCE patients compared to patients without GCE. CTP has a high specificity and positive predictive value. These initial results support further work in this field to evaluate the effects of GCE on cerebral perfusion and its association with poor outcomes.

Development of an MR Compatible Circulating Water Bath for Phantom Temperature Control: Design, Experimental Validation, and Applications in Neuroimaging Research

Pate, K.·Dehkharghani, S.·Magrath, R.·Wei, L.·Mao, H.·Tong, F.·Oshinski, J.
Emory University
Atlanta, GA.

Purpose

Refined temperature control is of paramount importance when probing phenomena sensitive to dynamic system temperatures, with widespread implications in neuroimaging research. Circulating water baths coupled to temperature control systems are used extensively throughout in vitro and in vivo magnetic resonance (MR) research for regulating temperature; however, commercially available products may be prohibitively costly. We propose that with limited components and experimental modeling, exquisite temperature control with an MR-compatible system can be achieved at nominal costs. Herein we report the design of a highly refined temperature control system constructed for optimization of MR thermometry sequences in a brain cytosol phantom.

Materials & Methods

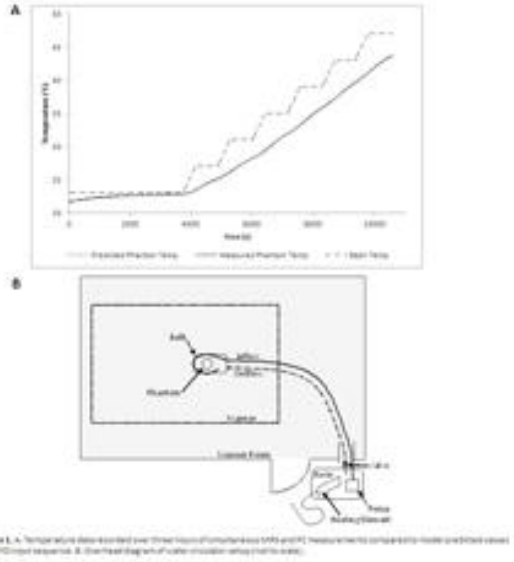
Basic construction consists of a 48-quart basin, submersible pump, two ball-valves, six-liter plastic bin, and tubing. Temperature was controlled by a proportional-integral-derivative (PID) controller connected to a 1000W heating element within the basin. The circulator was designed to control brain cytosol phantom temperatures during 1H-spectroscopy (MRS) and water phase-contrast (PC) measurements. The submersible pump was placed in the basin, powering the inflow into a bath housing the phantom in the MR scanner. The basin remained outside the scanner room, accessing the bath through a wall port. Water return to the basin was achieved by establishing a siphon, and the outflow rate was controlled by a ball-valve at the terminal end. A steady state waterline was demarcated in the basin, ensuring safe control of the phantom bath level in the scanner. Total system cost was approximately $180.00.

Results

The temperature difference between basin water and phantom was used to determine a relationship that modeled the time-dependant temperature response in the phantom. The model requires an input sequence of temperatures for the water in the basin, as well as initial phantom temperature. System accuracy was tested by a PID input sequence ramping phantom temperatures from 23 - 42°C over two hours. The phantom then was placed in the MRI scanner where actual reference temperatures were recorded via MR-compatible fiber optic probes (OpSens OTG-MPK5) during simultaneous MRS and PC MR thermometry (Figure 1). System testing confirmed stability and control over the range of target temperatures (± 0.1°C

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

over 20 minutes).



Conclusion

Preliminary testing for MR thermography techniques in the brain requires a refined system for temperature control. We show that construction of an MR-compatible system with predictable control is readily achievable at nominal comparative costs, affording examination of MR protocols for temperature measurement across a broad range of temperatures.

Comparison of the Macintosh Operation System and Grid Computing System on Anatomical Volume and Cortical Thickness Measurements

Liu, H.[1]·Chen, S.[1,2]·Yang, C.[1]·Huang, A.[2]·Liu, M.[2]
[1]National Taiwan University Hospital, Taipei, TAIWAN, [2]Center for Dynamical Biomarkers and Translational Medicine, National Central University, Jhongli, TAIWAN.

Purpose

FreeSurfer is a well known software package to measure cerebral cortical volume and thickness. However, it is CPU-intensive (20-30 hours per brain for a full segmentation). Grid computing is a loosely coupled, heterogeneous dispersing computer resources from multiple domains but dedicate to a particular application. Grid computing is faster than a single computer in the factors of the total number of computers in the grid.

Materials & Methods

We compared the results of cerebral cortex and volume in different anatomical locations in 118 subjects obtained from a Macintosh computer and a Grid computing (consisted of 48 personal computers with same configurations). They were 71 women (age mean = 45.9 years old, SD = 16.1) and 47 men (age mean = 42.8 years old, SD = 17.4). The exclusion criteria: evidence of psychiatric illness within the past two years, including substance abuse, a history of recreational drug use in the previous six months, a history of CNS disease or brain injury, any MR imaging abnormalities checked by two experienced neuroradiologists. MR scans were acquired with a 1.5T scanner (GE Healthcare, Wisconsin, USA). Coronal T1-weighted images were obtained using an MP-RAGE sequence with TR = 8.9 msec, TE = 2.99 msec, TI = 600 ms and a flip angle of 12. The slice thickness was 0.9 mm with no interslice gap. The image matrix was 256 x 256. The FreeSurfer comprises two main processing streams, a volume-based stream and a surface-based stream. The volume-based stream is designed to assign a neuroanatomical label to each (sub) cortical voxel, whereas the surface-based stream is developed to derive the white and pial surfaces from which, among others, cortical volumes and cortical thickness (CT) are derived. Both of them used the version 5.1.

Results

No statistic difference found between the two computing methods in all of the 42 subcortical and 68 cortical regions in volume and thickness measurement. The p ranged between 0.772 to 1.

Conclusion

With grid computing, we can obtain the volume and cortical thickness of different cerebral anatomical regions much faster than one computer with comparable results.

Detection of Pituitary Incidentalomas on High Spatial Resolution 3D MR Imaging: Detection Rate, Size and Distribution

Tavares, F. C.·Zan, E.·Aygum, N.·Blitz, A. M.
Johns Hopkins Hospital
Baltimore, MD.

Purpose

3D high-resolution MRI (HR MRI) may increase sensitivity for small lesions of the skull base. In certain cases the detection of pituitary microadenomas remains challenging, due partly to their small size. We hypothesized that detection of small pituitary incidentalomas, as a proxy for symptomatic microadenomas, would increase using high-resolution images.

Materials & Methods

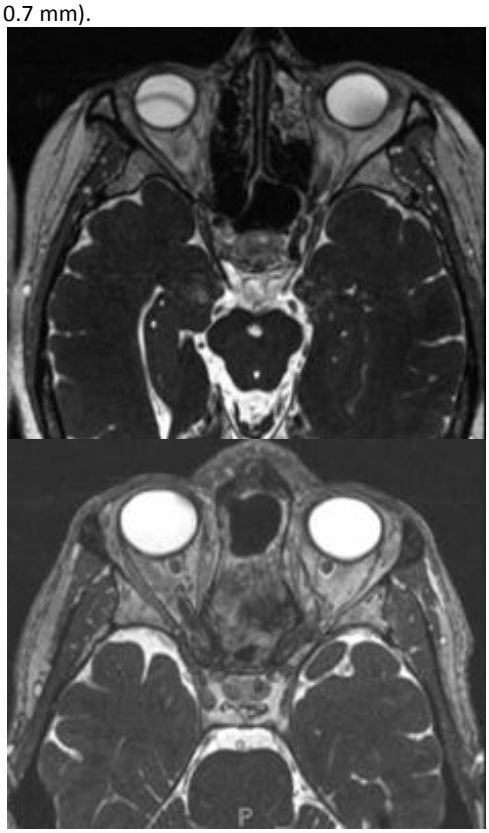
We retrospectively studied the rate of pituitary incidentalomas in 101 patients who underwent HR MRI. The protocol included isotropic 0.6 mm CISS and 0.8 mm VIBE sequences, which were reviewed for focal signal abnormality within the pituitary gland.

Results

We excluded 41 cases due to known/clinically suspected

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

pituitary pathology, prior surgery or pituitary region radiation. The pituitary was normal in 50 subjects, while 10 (20%) demonstrated focal signal abnormalities, with no quadrant predilection. We found five (10%) enhancing (Figure1) pituitary masses (minimum size of 1.9 x 1.4 mm) and five (10%) nonenhancing lesions (Figure 2), the latter classified as pars intermedia cysts (minimum size of 0.9 x 0.7 mm).



Conclusion
To our knowledge, the minimum size of incidentalomas detected on 3D MRI has not been studied. The reported incidence of pituitary incidentalomas is up to 27% in autopsy cases and 22.5% in diagnostic images. Although our initial cohort did not show a higher incidence, smaller abnormalities were detected than typically are seen on standard imaging.

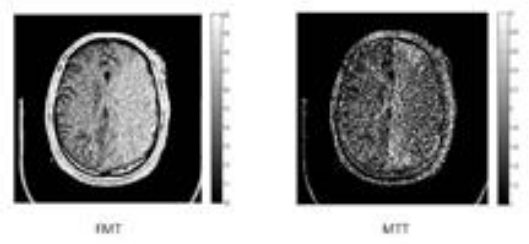
Rapid Determination of Perfusion Deficits for Acute Stroke Triage Using CT Perfusion

Chang, J. P.·Parekh, N.·Cantrell, C.·Gallagher, T.·Carroll, T. J.
Northwestern University
Chicago, IL.

Purpose
To develop and validate improved computed tomographic cerebral perfusion (CTP) images. We hypothesize that CTP, which parameterize altered perfusion in a setting of acute ischemic stroke, can be more easily implemented and better quantified using an arterial input function (AIF) independent, first moment of time (FMT) analysis, than more commonly used AIF dependent deconvolution analysis methods, which are subject to well known bolus delay and dispersion effects.
Materials & Methods
Retrospective review of patients (n=50) on PACS who received a CTP over a two-year period (1/2010-9/2012) and selected 10 consecutive patients who also received a follow-up head CT at least 10 days following the stroke. No patients in this study underwent thrombolysis (chemical or mechanical) in the time between CTP and follow-up imaging. Parametric images of relative cerebral blood flow (rCBF), relative cerebral blood volume (CBV), and mean transit time (MTT) color maps were obtained using standard deconvolutional methods with AIFs selected by a trained operator. The images then were reprocessed using a fully automated, nondeconvolutional method and FMT color maps were obtained and compared to the corresponding MTT maps. Differences in lesion conspicuity were quantified between MTT and our proposed approach based on an "asymmetry index" which quantified R/L asymmetry in a less objective manner than visual inspection. Discrepancies between MTT and FMT results were adjudicated through independent, blinded review of the follow-up CT images by two radiologists to determine which method was more predictive of final stroke volume.
Results
Preliminary results demonstrate that qualitatively, FMT has excellent concordance with the AIF dependent MTT. Mean absolute asymmetry scores were 0.104 and 0.185 for FMT and MTT respectively. Student *t*-test was calculated from the mean asymmetry index and demonstrates subtle statistically significant difference between FMT and MTT (p value=0.046). Qualitative evaluation demonstrates that FMT more closely matches the final stroke volume.



Conclusion
Using a fully automated, AIF independent,

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

nondeconvolutional method for identification of perfusion abnormalities is equivalent to standard MTT deconvolutional methods currently available without the inherent limitations of AIFs. Preliminary results also demonstrate that FMT has qualitatively higher specificity than MTT in predicting final stroke volume. Our method, as an adjunct to standard methods, has the potential to save precious time during an acute stroke workup, leading to a higher probability of salvageable brain tissue, and in situations of acute infarct, better predict the final stroke volume, allowing for more specific and personalized after stroke care planning.

Cerebrovascular Plaques: Association with Cerebral Microbleeds and Cerebrovascular Ischemic Events

Park, D.[1,2]·Lee, Y.[2]·Lee, S.[2]·Park, C.[1,2]
[1]Hanyang University Guri Hospital, Guri-si, KOREA, REPUBLIC OF, [2]College of Medicine, Hanyang University, Seoul, KOREA, REPUBLIC OF.

Purpose
The purpose of this study is to evaluate the correlation of cerebrovascular plaque characters, the presence of cerebral microbleeds (CMBs) and cerebrovascular ischemic (CVI) events.
Materials & Methods
Thirty-five consecutive patients (18 men; 17 women; mean age, 62.1 years) underwent vessel wall MRI studies including high-resolution T1-, T2-, proton density, and contrast-enhanced T1-weighted images and MR angiography for cerebrovascular plaque at 3T. Cerebral microbleeds were studied using T2*-weighted GRE sequences and/or susceptibility-weighted images. Plaques are characterized based on their composition. Intraplaque hemorrhage (IPH) and adventitial enhancement (AE) are categorized by T1 and T2 hyperintensity and contrast enhancement. Patients are classified with recent CVI events. Chi-square and multiple logistic regression analyses, as well as ROCs, are calculated.
Results
Intraplaque hemorrhage and AE are present in 29% and 82% of patients, which are associated with recent CVI events (P value < 0.05). The prevalence of CMBs is 21%, which is significantly higher in the patients with recent CVI events (P value < 0.05). A statistically significant association is observed between the presences of IPH, AE and CMBs (P value < 0.05). Correlation analysis demonstrates an association between the number of CMBs and the recent CVI events (P value < 0.05).
Conclusion
In conclusion, there is an association between the presence of IPH, AE, CMBs and recent CVI events. The presence of CMBs may represent an indicator of cerebrovascular symptom severity.

Desmoteplase in Acute Ischemic Stroke: Role of Imaging in the Ongoing DIAS-3 and DIAS-4 Clinical Trials

Albers, G. W.[1]·von Kummer, R.[2]·Truelsen, T.[3]
[1]Stanford University Stroke Center, Palo Alto, CA, [2]Technical University, Dresden, GERMANY, [3]Lundbeck A/S, Valby, DENMARK.

Purpose
Thrombolytic treatment of acute ischemic stroke (AIS) patients should be focused on those who are likely to benefit from thrombolysis and tissue reperfusion and unlikely to be harmed. It is logical that only patients with thrombo-embolic arterial occlusion can benefit who have not yet had major cerebral ischemic injury of the arterial territory affected. In the three completed trials within the Desmoteplase In Acute Ischemic Stroke (DIAS) clinical trial program, MRI and perfusion/diffusion mismatch failed to select patients for thrombolytic treatment. Desmoteplase is a novel, highly fibrin-specific thrombolytic agent. Here we review the results of the completed clinical trials, and provide the rationale for patient selection based on nonenhanced CT and CTA or DWI and MRA in the ongoing trials based on imaging.
Materials & Methods
Publications on completed trials and status update given by the sponsor on ongoing trials.
Results
In the two phase II trials (DIAS, DEDAS), desmoteplase had acceptable safety profiles, and showed superior reperfusion compared to placebo in patients selected by perfusion/diffusion mismatch. While the DIAS-2 phase III trial also supported the safety profile of desmoteplase, it did not replicate the positive efficacy findings. Clinical response was 47% and 36% for 90 and 125 µg/kg desmoteplase, respectively, and 46% for placebo. In DIAS-2, it appeared however, that 70% of the mismatch-selected patients presented with normal flow or low-grade stenosis (TIMI 2-3) at screening. Post-hoc analyses of the completed DIAS, DEDAS and DIAS-2 trials showed that desmoteplase was superior to placebo in patients presenting with TIMI 0-1 (occlusion or high-grade stenosis [OR 4.1 (1.4-12.3)], in contrast to TIMI 2-3 [OR 1.1 (0.5-2.4)]. These findings provided the basis for the design of the ongoing DIAS-3 and DIAS-4 phase III trials (n=880 in total). The objective of both trials is to evaluate the safety and efficacy of a single IV bolus injection of 90 µg/kg desmoteplase given 3-9 hours after onset of AIS. Patients are included with TIMI 0-1 in proximal cerebral arteries as assessed by MR or CT angiography. Signs of extensive early infarction on CT or MRI is an exclusion. Primary efficacy parameter is achieving a modified Rankin Scale score 0-2

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

at day 90. Other outcomes include NIHSS score, recanalization in patients with follow-up angiography, and clinical outcome in patients with core lesion <25 mL, or with perfusion/diffusion mismatch. Safety outcomes comprise mortality, symptomatic ICH, symptomatic ischemic edema, and other major hemorrhagic events. Mid-2012, total enrollment in DIAS-3 and DIAS-4 passed 500. DIAS-3 enrolls patients originating from sites in Europe, Asia and Australia; DIAS-4 from Europe, Latin America and North America.
Conclusion
The results of the DIAS clinical trial program will be important for physicians and patients with AIS in need of a safe and effective treatment in a time-window of up to nine hours.

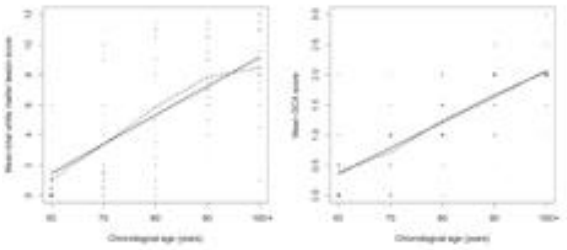
Clinical Neuroimaging in the Second Century of Life: Evidence for Altered Susceptibility to Age-Related Processes

O'Dowd, S. M.[1]·Chu, T.[2]·Taylor, T. R.[1]·Dineen, R. A.[2]
[1]Nottingham University Hospitals NHS Trust, Nottingham, UNITED KINGDOM, [2]University of Nottingham, Nottingham, UNITED KINGDOM.

Purpose
The World Health Organization predicts a 1000% increase in centenarian numbers globally by 2050, but neuroimaging changes in extreme old age are not well characterized. Epidemiological research shows that 85% of centenarians have avoided or delayed the onset of major age-related diseases. We model age-related neuroimaging changes [white matter lesions (WML) and cerebral atrophy] in a cohort of 60 to 100+ year-olds to test if these increase linearly or nonlinearly, and test the hypothesis that mean WML and atrophy scores in centenarians will fall below the expected mean based on linear modelling.
Materials & Methods
Retrospective cross-sectional study of clinically acquired cranial CT scans from 40 centenarians (34 female, mean age 101.7 years, range 100.0-110.6), and cohorts aged 60, 70, 80 and 90 years (n = 40 each group) matched for gender and type of presentation. Two neuroradiogists, blinded to all demographics, independently rated the cranial CT scans using validated published scales for global cortical atrophy (GCA; scored 0-3) and WML burden (scored 0-3 for right and left frontal and parietal regions, maximum score of 12). We assessed the possibility of nonlinear association between age-related neuroimaging changes and chronological age in a linear regression model. To test the stated hypothesis, we estimated the deviation of the observed mean WML or GCA score at 100 years from the group mean predicted by the linear models and tested for the significance of their differences.
Results
Each increase of 10 years in age was associated with 0.43 increase in GCA score (95% CI: 0.38-0.48, P<0.01) and 1.92 increase in WML score (95% CI: 1.62-2.23, P<0.01). There was insufficient evidence to support a nonlinear relationship for age-related increases in WML (P = 0.14) or GCA (P = 0.74) scores [Figure: Relationship between WML (left) and GCA (right) scores and age; Circle size proportional to number of patients; Solid line: regression model with age as continuous explanatory variable; Dotted line: regression model with age as categorical variable]. For centenarians, the observed mean total WML score was 1.77 units (95% CI: -3.27 to -0.27, P = 0.02) lower than the predicted mean score but the corresponding difference for mean GCA score was not statistically significant.



Conclusion
Atrophy and WML burden increase with age linearly. However, centenarian's mean WML scores were lower than expected from a linear trend, partially supporting the proposed hypothesis and the notion that biological aging mechanisms may be inherently different in centenarians.

Detection of Crossed Cerebellar Diaschisis in Patients with Acute Cerebral Infarction by CT Perfusion Using 320-Detector Row CT

Kinoshita, T.·Kinoshita, F.·Umetsu, A.
Research Institute of Brain and Blood Vessels-Akita Akita, JAPAN.

Purpose
Crossed cerebellar diaschisis (CCD) is characterized by a reduction in blood flow and oxidative metabolism in the cerebellar hemisphere contralateral to a supratentorial lesion. Crossed cerebellar diaschisis consistently results from circuit inactivation, such as cerebral infarction. Whole brain CT perfusion analysis using 320-detector row CT permits the identification of remote effect perfusion abnormalities. The purpose of this study was to assess the detection of CCD after acute middle cerebral artery (MCA) infarction using 320-detector row CT.
Materials & Methods
Consecutive 24 patients with unilateral MCA infarction in less than six hours from the onset of symptoms were

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

included. We excluded patients with abnormalities in the posterior fossa on unenhanced CT. CT perfusion study was performed using a 320-detector row CT. Image acquisition was performed as a dynamic contrast material-enhanced scan covering the entire brain. Perfusion maps were generated using CTP analysis software. CT perfusion color maps including cerebral blood flow (CBF) and cerebral blood volume (CBV) of the whole brain were obtained. The degree of CCD was measured on one axial cut representing the highest cerebellar asymmetry. Asymmetry index (AI) was calculated as a difference in the value between unaffected and affected cerebellar hemisphere divided by the value in the unaffected cerebellar hemisphere. Patients with AI more than 0.1 and those with AI equal to 0.1 or less than 0.1 were classified as CCD-positive and CCD-negative, respectively.

Results

Complete coverage of the posterior fossa was acquired in CT perfusion study in all patients. A total of 17 of 24 patients were identified to demonstrate asymmetrical cerebellar blood flow. In the remaining seven patients, CCD was negative at both CBF and CBV maps. Among the 17 CCD-positive patients at CBF maps, AI was 0.151 ± 0.034. Asymmetrical cerebellar blood volume was demonstrated in 10 patients. Among the 10 CCD-positive patients at CBV maps, AI was 0.154 ± 0.036.

Conclusion

Our results suggest that both CBF and CBV maps can evaluate CCD induced by acute MCA infarction. Cerebral blood flow maps are more sensitive than CBV maps for the detection of CCD. CT perfusion using 320-detector row CT is helpful in identifying CCD.

MR-Based Oxygen Extraction Fraction Using Spatial Independent Component Analysis of Breath-Hold PARSE Acquisitions

Cantrell, C. G.·Menon, R. G.·Vakil, P.·Johnathan, S.·Carroll, T. J.
Northwestern University
Chicago, IL.

Purpose

Cerebral oxygen extraction fraction (OEF) has been shown to be an independent predictor of stroke risk. Increased hemispheric OEF was linked to poor long-term outcomes. We have developed a means of quantifying OEF with MRI using PARSE. Observation of OEF alteration under mild physiologic stress induced by breath-holding reflects cerebrovascular reserve which may provide complimentary information on collateralization, and correlate with favorable outcome to revascularization therapy. We present an analysis of breath-hold MR OEF images using spatial independent component analysis (sICA). Traditionally, ICA analysis is performed in the time domain and component selection is motivated by anatomical landmarking and often manual selection, and the associated biases. We present here a sICA analysis of raw free-induction decay signals, which is completely independent of the normal bias associated with anatomical landmarking.

Materials & Methods

PARSE acquisitions acquired a 2D k-space volume using a well described rosette trajectory in 65 ms. By acquiring 20 PARSE datasets (1/5 seconds) and inducing a short 15 second breathhold we are able to observe frequency shifts (δω) resulting from increased deoxyhemoglobin in the draining veins of the head, similar to BOLD contrast. These 4-10 Hz shifts are denoised using sICA with spatial coordinates defined as the length along the PARSE readout and temporal domain being the 20 time points separated by ΔT=5 s. Spatial ICA uses blind-source separation to extract time courses, which correspond to bulk signal enhancement associated with the breath hold. Only the time courses that showed an enhancement of greater than 20% during breath hold were used to reconstruct the denoised free-induction decay signal; allowing us to create a signal containing only the dynamic components affected by the induced stress.

Results

Figure 1 shows a comparison between 20 consecutive MR OEF images created before and after sICA analysis. Though little can be deduced from the time course created before denoising, the sICA images clearly show a frontal shift in OEF during the period of induced stress followed by a return to the baseline after the stress is removed.

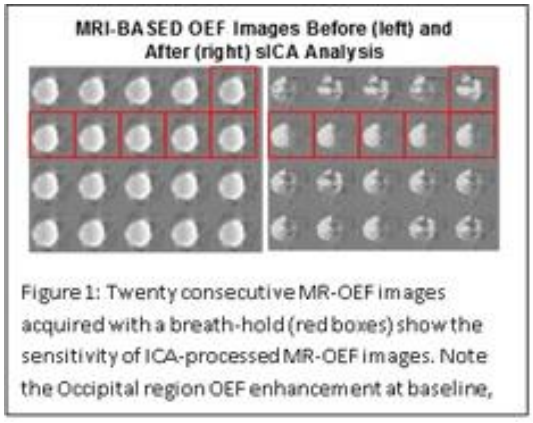

Figure 1: Twenty consecutive MR-OEF images acquired with a breath-hold (red boxes) show the sensitivity of ICA-processed MR-OEF images. Note the Occipital region OEF enhancement at baseline,

Conclusion

We have found that MR PARSE has high sensitivity to frequency shifts induced by transient alterations in deoxyhemoglobin. The use of ICA to extract and quantify cerebrovascular reactivity represents a new simple, noncontrast approach to stratifying patients toward therapies to prevent stroke.

Comparison of CT and MR Imaging ASPECTS Score in Acute Ischemic Stroke

Nguyen, T.·Culbertson, C. J.·Lau, H.·Masoud, H.·Romero, R. J.·Norbash, A. M.·Mian, A.
Boston Medical Center
Boston, MA.

Purpose
Acute ischemic stroke (AIS) patients with small area of infarction by imaging, but severe clinical deficits are potential candidates for endovascular treatment. However, brain CT may not be as accurate as MRI in determining the area of core infarction. We aimed to compare brain CT and MRI-defined area of core infarct in patients who were candidates for acute stroke intervention, based on calculation of ASPECTS scores.
Materials & Methods
Patients with AIS between August 2007 to July 2012 were reviewed retrospectively. Inclusion criteria were AIS with NIHSS $\geq$ 8 and brain CT/MRI performed within four hours of symptom onset. A neuroradiologist (AM) and vascular neurologist (TN) independently rated 71 CT and MRI ASPECTS scores on two separate occasions. Discrepancy was defined as frequency of mismatch of ASPECTS score dichotomized as <7 versus $\geq$7.
Results
Eight hundred sixty-six AIS patients presented during the study period. Five hundred twenty-one were excluded due to NIHSS <8. Two hundred sixty-seven patients did not have brain imaging within four hours, and seven were excluded due to infarctions in multiple cerebral arterial territories, yielding 71 patients eligible for the study. Of the 71 patients [39 women, mean age (+/- SD) 69 years $\pm$ 4 years] mean NIHSS was 15 $\pm$ 1. A large vessel occlusion (LVO) was present in 52%. Interval between CT and MRI was 90 minutes (n = 25 patients), three hours (n = 61 patients), and four hours (n = 71). Inter-rater observer agreement for ASPECTS score $\geq$ 7 and <7 showed good reliability for CT (k = 0.62) and MRI (k = 0.67). CT MRI discrepancy was associated with presence of LVO ($p<0.003$), but not associated with age, time delay between imaging studies, or time from symptom onset. Among patients with LVO, concordant frequency for good CT and MRI ASPECTS score ($\geq$7) was 56% for the neuroradiologist rater, and 51% for the neurologist rater.
Conclusion
In a subset of patients with acute ischemic stroke, discrepancy between CT and MRI-based ASPECTS score was seen in nearly half of the cases, and more frequent in the presence of large vessel occlusion.

Pooled Assessment of Computed Tomography Interpretation in the STRokE DOC Telestroke Network: Agreement between Spoke Radiologist, Hub Vascular Neurologist, and Central Read

Spokoyny, I.[1]·Raman, R.[1]·Ernstrom, K.[1]·Demaerschalk, B. M.[2]·Lyden, P. D.[3]·Hemmen, T. M.[1]·Guzik, A. K.[1]·Chen, J. Y.[1,4]·Meyer, B. C.[1]
[1]University of California San Diego, San Diego, CA, [2]Mayo Clinic, Phoenix, AZ, [3]Cedars Sinai Medical Center, Los Angeles, CA, [4]San Diego VA Medical Center, San Diego, CA.

Purpose
The American Stroke Association guidelines emphasize the need for high-quality studies assessing agreement of radiologists and nonradiologists engaged in emergency telestroke decision-making. The objective of this pooled analysis is to determine the level of agreement between central read and each of two groups (spoke hospital radiologists and hub hospital vascular neurologists/tele-strokologists), in interpreting brain CT scans of patients presenting to telestroke hospitals with acute stroke.
Materials & Methods
The Stroke Team Remote Evaluation Using a Digital Observation Camera (STRokE DOC and STRokE DOC-AZ TIME) trials were prospective, randomized, outcome-blinded trials comparing audiovisual telemedicine with teleradiology stroke evaluations to telephone-only consultations. These two trials assessed eligibility for IV rt-PA and correctness of decision-making for two hubs and six spokes. In each trial, the subjects' CT scans were interpreted by the hub tele-strokologist in the telemedicine arm, and by the spoke radiologist in the telephone arm. In this analysis, a central read was performed for each trial by adjudicating committees blinded to treatment arm and outcome. The data were pooled and results reported for the entire population. Baseline characteristics were compared between hub sites. Kappa statistics and exact percent agreement rates were used to assess interobserver agreement for acute-stroke-related radiographic issues such as contraindication to rt-PA, presence of ICH, SAH, SDH, tumor, hyperdense artery, acute stroke and normal scan.
Results
Two hundred sixty-one subjects who underwent assignment to telemedicine or telephone and had CT reads completed were analyzed. The overall agreement for presence of radiologic contraindications to thrombolysis was excellent (95.4%, κ = 0.74, 95%CI 0.59-0.88) and was slightly higher for hub tele-strokologist (96.2%, κ=0.81, 95%CI 0.64-0.97) than for spoke radiologist (94.7%, κ=.64, 95%CI 0.39-0.88) when each was compared to central read. When excluding patients in whom the degree of early ischemic changes was the reason for potential radiographic contraindication to rt-PA, the agreement was even stronger (98.3%), with 100% tele-strokologist agreement with central read. For the rt-PA treated subset

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

(N=65), overall agreement was 98.5%, and tele-strokologist agreement with central read again reached 100%. Secondary outcomes included agreement on presence of: normal scan (74.6%, 77.1%), acute stroke (74.6%, 77.9%), intracerebral hemorrhage (99.2%, 98.5%), subarachnoid hemorrhage (98.5%, 96.9%), subdural hematoma (100%, 100%), tumor (100%, 97.7%), and hyperdense artery (93.8%, 88.5%) for hub tele-strokologist and spoke radiologist respectively, versus central read.
Conclusion
In the context of a combined telestroke network designed to assess patients with acute stroke syndromes, this pooled analysis found that both tele-strokologists and spoke radiologists had excellent central agreement in identifying radiologic contraindication to rt-PA treatment. The agreement was slightly higher for tele-strokologists. This effect also was seen in the rt-PA treated subset. When excluding those CT scans with more significant degree of early ischemic changes (where rt-PA treatment is potentially controversial even amongst experts), the agreement between tele-strokologists and central read was perfect. These pooled findings demonstrate, in a larger sample size, that tele-strokologists are effectively able to interpret brain CT scans for the purpose of determining appropriateness of rt-PA administration in the setting of acute stroke.

Regionally Specific Cortical Thickness Differences in Acute Stroke

Young, B. M.·Nair, V. A.·La, C.·Gupta, J.·Dabbs, K.·Reiter, P.·Nadkarni, T.·Chacon, M.·Jensen, M. B.·Sattin, J.·Prabhakaran, V.
University of Wisconsin Madison
Madison, WI.

Purpose
Cortical thickness changes after stroke are not well documented with little known about associations between cortical thickness and behavioral performance in the acute stage. Given the relationship between cortical thickness and cognitive performance in healthy aging and disease populations (e.g., multiple sclerosis), we examined if a similar relationship exists in acute stroke.
Materials & Methods
Twenty patients with acute ischemic stroke were scanned within seven days of stroke onset on a General Electric 3T MRI scanner. High-resolution whole brain 3D T1-weighted BRAVO FSPGR 1mm isotropic images were collected and then processed with Freesurfer version 5.1.0. Eleven acute stroke patients' (average age = 63 years, seven M, seven cortical stroke) data were further analyzed after inspection for correct cortical surface reconstruction. Age-matched healthy controls (n = 15, average age = 57 years, six M) were scanned with the same parameters. We looked for differences in the correlation between cortical thickness and letter fluency performance, controlling for age. Letter fluency (word generation) measures were collected outside the scanner and corrected for age and education.
Results
There was a significant difference in the correlation between cortical thickness and age ($p<0.01$, uncorrected), with patients showing more thinning in the rostral middle frontal region. Analyses investigating cortical thickness-verbal fluency correlations identified the left inferior temporal region as correlated with performance with significant differences ($p<.003$, uncorrected) between patients (average thickness = 2.6 mm) and normals (= 2.9 mm). Cortical thinning was associated with poorer performance and also seen in patients in the right insular ($p<.003$, uncorrected) regions.
Conclusion
Cortical thinning changes that have occurred over chronic time periods have been associated with cognitive performance in other disease populations. These results suggest that regional cortical thinning changes can be seen even in the acute time period after a stroke and may be predictors of cognitive performance.

KEYWORDS: Cortical thickness, Acute stroke

Value of the 3D Arterial Spin Labeling MR Imaging for Evaluating the Cerebral Perfusion in Patients with Cerebrovascular Stenosis: A Comparative Study with 123I-Iodoamphetamine Single Photon Emission CT

Furukawa, M.·Iida, E.·Matsunaga, N.
Yamaguchi University
Ube, JAPAN.

Purpose
Arterial spin labeling (ASL) MR imaging is an emerging technique for noninvasive measurement of cerebral perfusion. 3D-gradient and spin-echo (GRASE) ASL can produce higher signal-to-noise ratio perfusion images with a high spatial resolution compared with 2D-multislice echo-planar imaging. The purpose of this study is to investigate the value of 3D ASL MR imaging for cerebral blood flow (CBF) assessment in patients with cerebrovascular stenosis.
Materials & Methods
Forty-three patients with unilateral or bilateral cerebrovascular stenosis underwent CBF evaluation by 3D ASL and 123I-iodoamphetamine (IMP) SPECT within a mean interval of four days (range: 0-30 days). All patients had no history of vascular surgery such as CEA or CAS, and did not have a major cortical infarction in the internal carotid artery (ICA) territory on conventional MR imaging. 3D-GRASE ASL was performed on a 3T MR unit with following parameters ((FOV 256 mm, matrix 64 x 64, 32 slices, TR/TE/TI 5,000/16/1,800 msec, FA 180 degree). Quantitative CBF and cerebrovascular reserve (CVR)

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

measurement by 123I-IMP-SPECT with a dual table autoradiography method was used as a standard reference. Side-by-side difference on 3D ASL MR imaging was evaluated visually by two radiologists, and those were compared with the SPECT findings for the MCA territory.
Results
Among total 43 patients, 26 patients had unilateral ICA or middle cerebral artery (MCA) stenosis, and the remaining 17 patients had bilateral stenosis on MR angiography. On rest SPECT scans, 20 patients showed >10% CBF difference between bilateral MCA territory, and 29 patients showed >5% CBF difference. On 3D ASL, 36 patients showed visual CBF difference between bilateral MCA territory. When a cut-off value of 10% was used on 123I-IMP-SPECT, the sensitivity, specificity, and diagnostic accuracy of 3D ASL were 90%, 21.7%, and 53.5%, respectively. When a cut-off value of 5% was used, the sensitivity, specificity, and diagnostic accuracy of 3D ASL were 86.2%, 21.4%, and 65.1%, respectively. Among 23 patients whose CBF difference was less than 10% on rest 123I-IMP-SPECT, 18 patients showed a side-by-side difference on 3D ASL, and 10 patients in those 18 patients (55.6%) showed >10% CBF difference on acetazolamide challenge 123I-IMP-SPECT.
Conclusion
Although 3D ASL MR imaging showed a low specificity, that might include the potentials for predicting the CVR. Three-dimensional ASL MR imaging is clinically applicable, especially as a noninvasive screening examination.

Uniform Extent and Degree of Cerebral Ischemia after Middle Cererbral Artery Occlusion in Rats: Use of Prospective 4.7T Diffusion MR Imaging

Yi, K.[1]·Cha, S.[1]·Lee, S.[1]·Lee, C.[2]·Lee, S.[3]
[1]Chungbuk National University Hospital, Cheongju, KOREA, REPUBLIC OF, [2]Korea Basic Science Institute, Cheonwon, KOREA, REPUBLIC OF, [3]Korea Research Institute of Bioscience and Biotechnology, Cheongwon, KOREA, REPUBLIC OF.

Purpose
For the translational research to evaluate therapeutic potential of any agent, there should be rat models with cerebral ischemia/infarction of very similar characteristics. And yet previous reports revealed middle cerebral artery occlusion (MCAO) models in rats presented very diverse results of cerebral infarction with the use of either sutures or macrospheres. This experimental study was to produce brain infarctions with uniform extent and level of ischemic damage after MCAO in rats.
Materials & Methods
A total of 19 rats were subject to left MCAO using the suture technique. Immediately after occlusion, the animals were transferred into an MRI scanner (4.7T) and diffusion-weighted imaging (DWI) of axial and coronal planes was repeated every 10 minutes to postocclusion 125 minutes (11 times). Every first MR imaging was started 15 minutes after stroke onset. Immediately after each DWI, the apparent diffusion coefficient (ADC) values were determined in the ischemic lesions and compared to the unaffected contralateral hemisphere. Successful MCAO was defined when the whole left MCA territory showed ADC abnormality on the first postocclusion DWI at 15 minutes.
Results
Territorial infarction was induced successfully in nine rats (9/19, 47.4%), and MCAOs in 10 rats were classified as failure. On initial postocclusion MR imaging at 15 minutes, the ADC values of the affected lesions were significantly lower than those of contralateral hemispheres (mean relative ADC value=0.77 ± 0.06), and remained stable in seven rats; however in two rats the ADC values decreased and reached lowest plateau in 45 and 55 minutes, respectively. Thus seven out of 19 MCAO cases had brain infarctions with very similar MR characteristics of lesion extent and temporal evolution of ADC abnormality.

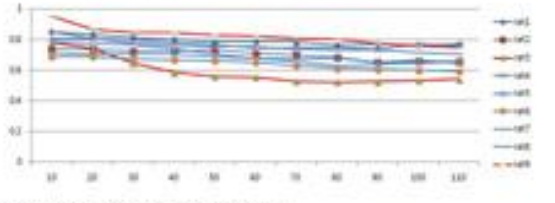

Fig 1. Temporal changes of relative ADC values.
In the ischemic lesions after left MCAO in nine cases, initially defined as successful, relative ADC values of the two showed different pattern of temporal evolution (red line) comparing to the those of the remaining seven (blue line).

Conclusion
Applying prospective diffusion MRI and judging the success of modeling very early on after MCAO, we could exclude any inhomogeneity of brain infarctions and produce uniform extent and level of ischemic damage in rats. This technique would make it possible to obtain homogenous group of murine stroke models for the translational research.

Institution of Dedicated Acute Stroke Protocol Helped in Achieving Target Door-to-CT Time and Thereby Faster Delivery of Thrombolytic Therapy

Strathearn, L.·Simpkin, W.·Phillips, S.·Shankar, J.
QE II Hospital
Halifax, NS, CANADA.

Purpose
Benefit of thrombolytic therapy for acute ischemic stroke is time dependent - earlier the better. Outcome of thrombolytic therapy depends on size of baseline infarct.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Optimal outcomes can be accomplished by rapid assessment of salvagable brain - penumbra and early treatment. Institution of proper Acute Stroke Protocol (ASP) helps expedite the whole process of imaging and therapy. We designed an Acute Stroke Protocol to facilitate this in eligible patients. The target Door-to-CT time was kept at 25 minutes. We assessed Door-to-CT time in our institution and its effect on patient's management and compared this before and after the institution of the Acute Stroke Protocol.
Materials & Methods
In November 2011, a group of health professionals designed an algorithm to standardize and expedite early imaging and management of patients who access Emergency Health Service for suspected acute ischemic stroke. Imaging paradigm included plain CT head, CT perfusion and CT angiogram of head as opposed to only plain CT head before Acute Stroke Protocol. A series of training lectures were organized for CT technologists and radiology residents on Acute Stroke Protocol imaging protocol. A database was prospectively collected to track outcomes. The Acute Stroke Protocol was launched on April 1, 2012. Door-to-CT and Door-to-Needle time were assessed as parameter for smooth and successful functioning of our Acute Stroke Protocol. Two sample t tests and ANOVA are used to compare these parameters before and after the institution of the Acute Stroke Protocol. p value less than 0.05 was considered significant.
Results
In first quartile of operation, 16 patients received thrombolytic therapy within significantly shorter Door-to-Needle time (p = 0.005; median-75 minutes) after arrival in the Emergency Department. Mean Door-to-CT time (24 minutes) was significantly shorter (p = 0.013) than that in previous nine months before ASP.
Conclusion
In Acute Stroke Protocol, added imaging provided better assessment of penumbra within significantly shorter Door-to-CT time. Proper education and awareness for technologists was critical in exceeding our goal of 25 minutes in the very first quartile. This resulted in better patient care. Regular auditing is important in smooth functioning of Acute Stroke Protocol.

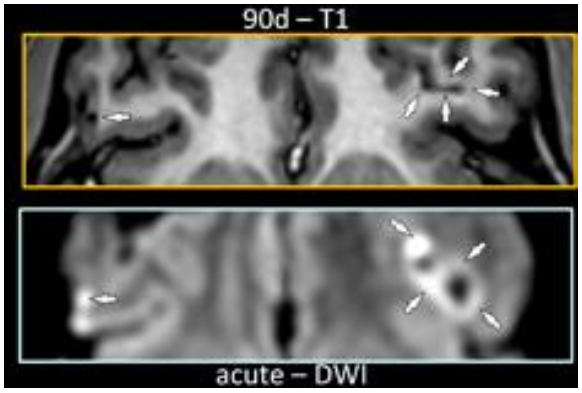
Post-Traumatic Focal Cortical Encephalomalacia Predicted by Focal Cortical Diffusion Abnormalities on Acute MR Imaging

Butman, J. A.[1]·Pham, D. L.[2]·Magrath, E.[2]·Latour, L. L.[3]
[1]The Clinical Center of the NIH, Bethesda, MD, [2]Center for Neuroscience and Regenerative Medicine, Bethesda, MD, [3]National Institute of Neurological Disorders and Stroke, Bethesda, MD.

Purpose
To demonstrate that post-traumatic focal cortical encephalomalacia (FCE) identified on MRI 1-3 m following mild to moderate TBI is preceded by anatomically correlated sites of focal cortical diffusion abnormality (FCDA) on acute MRI obtained within 48 hours of the TBI.
Materials & Methods
Patients (n = 38) with head injury presenting to the Trauma/ED were enrolled in the Center for Neuroscience and Regenerative Medicine Traumatic Head Injury Neurioimaging Classification (THINC) study. MR imaging was obtained within 48 hours of injury and at 1-3 month followup. MR imaging included a 3D T1 IR SPGR (~ 1 mm isotropic), and isotropic trace diffusion-weighted images (isoDWI), computed from 15 direction b=1000 DTI obtained at 3.5 mm slice thickness. First, follow-up 3D T1 images were reviewed to identify focal cortical encephalomalacia (FCE). Next, the acute isoDWI were evaluated for sites of hyperintensity involving the cortical gray matter. Finally, the cases of discordance between the two interpretations were reviewed with all imaging data available to understand the basis for the discordance.
Results
A total of 18 sites of FCE were identified on the follow-up 3D T1 in five patients. Focal cortical encephalomalacia was characterized by complete loss of the ribbon of cortical gray matter such that white matter was “exposed” to CSF at 17/18 sites. One site demonstrated cortical thinning. In the five patients with FCE, the acute MRI demonstrated corresponding sites of FCDA(Figure). In two patients, FCDA was present acutely, but no FCE was identified on the follow-up MRI, even in retrospect. No patients with FCE on the follow-up scan had a normal acute isoDWI. In 24 patients, no FCE or FCDA was identified. Thus, FCE was highly associated with FCDA (P=0.00012, Fisher’s exact test).

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Conclusion
Much attention has been directed towards the white matter injuries that result from TBI as well as to global/quantitative measures of atrophy. Here we identify focal cortical gray matter encephalomalacia as a relatively common consequence of mild to moderate TBI. In most cases, the presence of FCDA developed into sites of FCE, whereas no FCE developed when FCDA was initially absent. In a manner analogous to the evolution of ischemic stroke, FCDA represents cytotoxic edema which can be identified readily by acute diffusion-weighted MRI, and, as in stroke, evolves to encephalomalacia. Thus, FCDA may represent gray matter "at risk" and represent a salvageable target for therapeutic intervention, motivating the use of MRI in the acute TBI setting.

Cervical Arterial Dissection: Presentation, Treatment and Outcome over a 5-Year Period at a Level I Trauma Center

Bagga, S.·Pastel, D. A.
Dartmouth Hitchcock Medical Center
Lebanon, NH, NH.

Purpose
Arterial dissections of the extracranial carotid and vertebral arteries occurs when a small tear forms in the innermost lining of the arterial wall. Blood enters the space between the inner and outer layers of the vessel, causing stenosis, complete occlusion or pseudoaneurym formation. Dissections, which are either traumatic or spontaneous in origin, are recognized as an underdiagnosed but serious cause of morbidity. With the increasing use of noninvasive imaging, including magnetic resonance and computed tomography angiography, the diagnosis of vascular dissection has increased in frequency. The combined incidence of both vertebral artery dissection (VAD) and carotid artery dissection (CAD) is estimated to be 2.6 per 100,000. Among all extracranial cervical artery dissections, CAD is 3-5 times more common than VAD.The incidence of carotid artery dissection as a result of blunt injuries (mainly high-speed motor vehicle accidents) ranges from less than 1% to 3%.The goal of identifying arterial dissections is to prevent cerebral infarctions. Management options include observation, medical therapy and endovascular intervention. Challenges remain, as no clear cut evidence-based guidelines exist about treatment and followup of these patients. The purpose of this retrospective study is to better understand the presentation, treatment and outcome in patients diagnosed with arterial neck dissections at a level I trauma center over a five-year period.
Materials & Methods
The RIS database will searched using keyword "Dissection" on all CTAs and MRAs performed for trauma between January 2006 and January 2011. Followup for all patients will be at least one year. The following data information will be collected through the electronic medical record system: location and severity of dissection (six), clinical or imaging evidence of for acute infarctions, findings on subsequent vascular neck imaging studies, and any medical or invasive treatments received for the vascular injury. The data will be de-identified as it is collected and a unique, encrypted study ID will be assigned to each case. Subgroup analysis of the treated vs. nontreated groups will be performed.
Results
Neuroimaging is helping in early diagnosis and treatment of cervical arterial dissections.
Conclusion
Our study will report the presentation, management, and outcome of patients with cervical arterial dissections and possibly identify features and treatments that predict favorable outcome.

High-Resolution MR Characteristics of Reversible Cerebral Vasoconstriction Syndrome

Obusez, E. C.·Cerejo, R.·Hajj-ali, R.·Hui, F.·Jones, S.
Cleveland Clinic Foundation
Cleveland, OH.

Purpose
High-resolution 3T MR imaging and MR angiography (HRMR) is an emerging tool for evaluating intracranial arterial disease. Diagnostic imaging considerations for reversible cerebral vasoconstriction syndrome (RCVS) traditionally include imaging of cerebral vessels with catheter angiography, CT or MR angiography, which focus on the arterial lumen. Other work demonstrates the advantage of HRMR in providing additional information about the arterial wall. However, followup of RCVS with HRMR has not been studied. The aim of this study was to determine HRMR vessel wall characteristics of RCVS during followup.

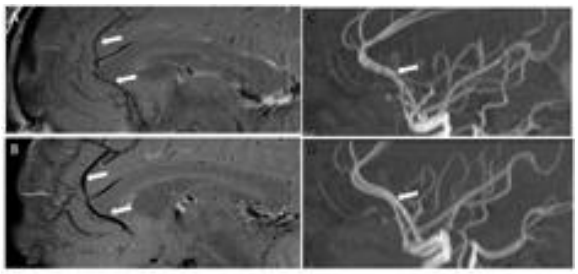
Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

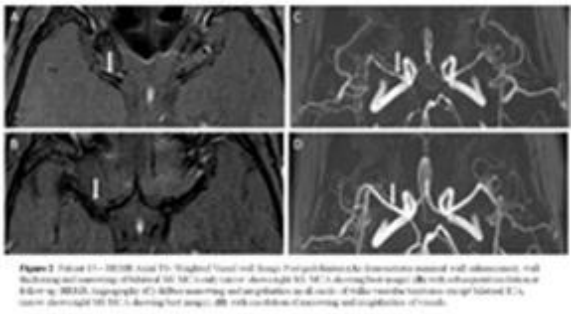
Materials & Methods

All patients at our institution with a diagnosis of RCVS that underwent HRMR were identified and retrospectively studied. High-resolution vessel wall imaging protocol included black-blood contrast-enhanced T1-weighted sequence with fat suppression and time-of-flight MRA of the circle of Willis. Clinical and demographic data and vessel wall characteristics including enhancement, wall thickening, and lumen narrowing, were collected.

Results

Thirteen patients with a mean age of 44.2 years were diagnosed with RCVS and underwent HRMR. Vessel wall findings during initial imaging included four patients with mild uniform wall thickening and enhancement, six patients with nonenhancing uniform wall thickening, two patients with no abnormality and one patient with only narrowing. All patients had clinical followup. Nine patients had follow-up imaging with median follow-up imaging period of two months of which eight showed improved imaging findings.





Conclusion

HRMR shows that uniform vessel wall thickening and luminal narrowing without or with mild enhancement are characteristics of RCVS.

Table: Follow-Up HRMR Vessel Wall Imaging Characteristics

		1st HRMR (MRI and MRA)					2nd HRMR (MRI and MRA)

Evaluation of Gadobenate Dimeglumine for Contrast-Enhanced MR Angiography

Pirovano, G.[1]·Kirchin, M.[2]·Parker, J. R.[1]
[1]Bracco Diagnostics Inc., Monroe, NJ, [2]Bracco Imaging, Milan, ITALY.

Purpose

Gadobenate dimeglumine is a higher relaxivity paramagnetic MR contrast agent currently approved in 48 countries for MRI of the brain and spine at an iv dose of 0.1 mmol/kg bodyweight and in certain countries for liver imaging at a dose of 0.05-0.1 mmol/kg. In the United States, this agent also is approved for magnetic resonance angiography (CE MRA) in adult patients with known or suspected renal or aorto-ilio-femoral occlusive vascular disease at a dose of 0.1 mmol/kg. As part of the registration of this agent with the US FDA, we identified and summarized published clinical studies on the use of this agent for contrast-enhanced magnetic resonance angiography (CE MRA).

Materials & Methods

We performed a Medline search using the terms “Multihance OR gadobenate dimeglumine or BOPTA” AND “magnetic resonance angiography or MRA”. Initially 168 citations were identified. After review to eliminate abstracts, animal studies, reviews, technical reports, and papers without original data, 96 original clinical publications were identified. These 96 papers were tabulated, evaluated and summarized.

Results

Publications reported on dosing of gadobenate dimeglumine, scanning optimization, comparisons with unenhanced MRA or carotid DSA, and comparisons with other gadolinium agents. In addition to the supraaortic arteries, represented by 21 published studies, all other major vascular territories were represented in the literature (peripheral = 22, abdominal = 17, thoracic or pulmonary = 9, whole body MRA = 8, coronary = 7, liver = 4, upper extremities = 4, multiple territories = 4). Most

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

neuroradiology studies used a dose of 0.1 mmol/kg bodyweight, although higher doses were sometimes reported in coronary, whole body, or peripheral MRA studies. Twenty-two studies reported comparative data. Most were intra-individual crossover studies in which each patient received gadobenate dimeglumine and another gadolinium agent in two separate exams. The comparators were gadopentetate dimeglumine (nine studies), gadofosveset (four studies), gadobutrol (three studies), gadoterate meglumine (three studies), and gadodiamide (two studies). In one study gadobenate dimeglumine was compared to both gadopentetate dimeglumine and gadobutrol. Typically, comparative studies reported better enhancement with gadobenate dimeglumine versus the comparator agent, despite the fact that in several studies a higher dose of comparator agent was given. No differences in safety were evident in any of the published papers with the other gadolinium agents.
Conclusion
Published clinical studies support the safe and effective use of gadobenate dimeglumine at a dose of 0.1 mmol/kg for CE MRA of supra-aortic vessels as well as a number of "below the heart" applications. Comparative trials suggest gadobenate dimeglumine may be administered at a lower dose that conventional ECF agents for CE MRA as a result of its higher relaxivity.

Aqueduct of Sylvius: 3T MR Imaging Morphology and Morphometry with Neuroendoscopic Relevance

Matys, T.[1]·Horsburgh, A.[1]·Kirollos, R. W.[1]·Antoun, N.[1]·Massoud, T. F.[2]
[1]Addenbrooke's Hospital, Cambridge, UNITED KINGDOM, [2]University of Cambridge, Cambridge, UNITED KINGDOM.

Purpose
Neuroendoscopic aqueductoplasty with optional stent placement is a therapeutic consideration for hydrocephalus due to a membranous or short segment stenosis of the aqueduct of Sylvius (AqSylv), as well as for decompression of an isolated fourth ventricle. The procedure can be performed through a transfrontal approach passing through foramen of Monro and the third ventricle, or a suboccipital trans-foramen magnum fourth ventricular approach. The few studies to date investigating the normal dimensions and contour of the AqSylv, which would be highly relevant to the above procedures, have been performed on cadavers or fresh-frozen specimens prone to shrinkage errors and distortion of normal anatomy. The aim of this study was to obtain precise in vivo morphometry of the normal AqSylv using high-resolution 3T MR images.
Materials & Methods
We retrospectively analyzed magnified midsagittal T1-weighted 3T MR images of 100 patients with normal brain imaging findings, aged 13-83 years (45 men and 55 women). We measured widths of the AqSylv pars anterior, ampulla, pars posterior, narrowest point, and its length. We recorded angulation of AqSylv relative to the intercommissural AC-PC line, angulation between the caudad and rostral part of the AqSylv, and its angulation relative to the fourth ventricle. We statistically determined age- and sex-related changes in AqSylv morphometry.
Results
Mean morphometric parameters of the AqSylv were as follows: width of the pars anterior 1.1 mm, ampulla 1.2 mm, pars posterior 1.4 mm, length 14.1 mm, narrowest point 0.9 mm. The entry into the AqSylv from the third ventricle was at a mean 26° angle to the AC-PC line. AqSylv then followed a gentle curve concave ventrally so that its caudad part was at a mean 32° angle to the rostral segment. The caudad segment was at a mean 18° angle to the forth ventricular floor. Diameters of the ampulla and pars posterior were slightly larger in males, but the other measurements were comparable between sexes. The widths generally correlated positively, and length correlated negatively with Evans' index (a surrogate marker for ventricular volume) and age; therefore, with increasing age and enlargement of the ventricular system, the AqSylv widens and shortens. However, AqSylv maintained its angles with age. There was a negative correlation between the AqSylv widths and length (apart from width of pars posterior), so that wider aqueducts also were shorter, and tended to be more curved. There was a

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

strong negative correlation between the rostral-caudad angle of AqSylv and angles of entry from the third or fourth ventricle, so that a steeper entry into the AqSylv from either ventricle is associated with less curvature along its course.

Conclusion

We present the first normative MRI dimensions of AqSylv obtained in vivo which, importantly, are at variance with published cadaveric morphometrics. We also present age- and sex-related changes in AqSylv size and curvature, and internal correlations between morphometric size parameters. Reported data are valuable in guiding neuroendoscopic management of hydrocephalus and aqueductal stenosis. Awareness of these normal morphometrics also is highly useful when stent placement is an option during aqueductoplasty.

Foramina of Monro: A New Look at 3D Spatial Configuration Based on Multiplanar 3T MR Imaging Morphometry Relevant to Neuroendoscopy

Matys, T.[1]·Horsburgh, A.[1]·Kirollos, R. W.[1]·Antoun, N.[1]·Massoud, T. F.[2]
[1]Addenbrooke's Hospital, Cambridge, UNITED KINGDOM, [2]University of Cambridge, Cambridge, UNITED KINGDOM.

Purpose

Connections between lateral and third ventricles have been confusingly characterized as either one or two foramina of Monro (FoM), and described as either Y-shaped, or T-shaped. This inconsistency is perpetuated on routine neuroimaging because standard orthogonal MRI projections do not match true anatomical spatial configurations of FoM, thus depicting them in a foreshortened or distorted manner. Knowledge of the precise 3D configuration of FoM has important implications for neuroendoscopic practice of traversing FoM (e.g., when creating third ventriculostomy). We therefore studied normal 3T MRI morphometry of FoM to establish detailed differences in shape and size on standard orthogonal imaging planes versus more representative features on 3D imaging in their true anatomical spatial orientation.

Materials & Methods

We first retrospectively reviewed standard 2D coronal T1-weighted images in 100 normal patients obtained on 3T MRI, and measured FoM minimal width, angle between the right and left FoM, their separation (fornix width), and length. We established the angle at which coronal images were acquired in relation to the intercommissural (AC-PC) line. We then repeated measurements on retrospective 3D FSPGR datasets from 50 separate patients (see Table). Measurements on these images were performed twice, in the plane replicating the standard coronal 2D plane, and also in the true anatomical plane of FoM obtained by 3D image manipulation of the coronal plane along a transverse line traversing FoM.

Results

Two-dimensional coronal images were acquired at 81±6° relative to AC-PC line; for morphometric data see Table. There was high concordance between 2D and 3D morphometrics in the plane replicating the standard coronal plane (set at 81°). The true anatomical plane of FoM was found at 31°±8° relative to AC-PC line. The minimal width of the FoM (2.4±0.5 mm) in this plane was significantly less than that apparent on standard coronal images (2.9±0.8 mm), and the angle between the two FoMs was larger (74±7° vs. 61±7°) owing to greater curvature of the thalamus forming the postero-infero-lateral wall of FoM. Interestingly, the mean length of FoM in its anatomical plane equaled its mean width (and in 61% of patients was actually larger), suggesting that in many instances the interventricular connections could perhaps be described as short "canals" rather than "foramina".

	2D coronal	3D coronal	3D anatomical
Age (years)	47 ± 16 (13-83)	48 ± 24 (19-82)	48 ± 24 (19-82)
Evans index	0.23 ± 0.04 (0.12-0.29)	0.23 ± 0.03 (0.19-0.29)	0.23 ± 0.03 (0.19-0.29)
Plane angle vs AC-PC (deg)	81 ± 6 (65-100)	81 (set)	31 ± 8 (20-39)
FoM minimal width (mm)	2.9 ± 0.6 (1.3-5.6)	2.9 ± 0.8 (1.6-4.8)	2.4 ± 0.5 * (1.2-4.0)
FoM length (mm)	2.3 ± 0.5 (1.0-3.7)	2.4 ± 0.5 (1.7-3.9)	2.4 ± 0.5 (1.6-4.0)
Fornix width (mm)	3.1 ± 0.7 (1.7-3.6)	2.8 ± 0.6 (1.9-4.2)	3.0 ± 0.9 (1.9-4.3)
FoM angle (deg)	58 ± 8 (36-84)	61 ± 7 (43-71)	74 ± 7 * (60-84)

Table: Patients' characteristics and morphometrics of FoM [mean ± SD (range)]. * p<0.001 vs. 3D coronal.

Conclusion

We provide the first detailed normal MRI morphometrics for FoM and show that: 1) their true size and orientation differ from those perceived on standard coronal images; 2) the right and left FoMs are clearly separate with V-shaped orientation; 3) each FoM is angled about 30°, 60°, and 35° to the axial (AC-PC line), coronal, and sagittal planes respectively; and 4) FoMs often have a 3D spatial configuration resembling short canals. Planning of neuroendoscopic procedures should ideally rely on 3D datasets and not standard 2D images.

Engraftment of Human Mesenchymal Stem Cells in a Rat Photothrombotic Cerebral Infarction Model: Comparison of Intra-Arterial and Intravenous Infusion Using MR Imaging and Pathologic Analysis

Byun, J.[1]·Kwak, B.[1]·Kim, J.[1]·Jung, J.[1]·Ha, B.[1]·Park, S.[1]·Shim, J.[1]·Kim, H.[2]
[1]Chung-Ang University Hospital, Seoul, KOREA, REPUBLIC OF, [2]Samsung Medical Center, Seoul, KOREA, REPUBLIC OF.

Purpose
To evaluate that administration routes affect the early stage migration of transplanted human bone marrow-derived mesenchymal stem cells (hBM-MSCs) in acute brain infarction.
Materials & Methods
Male Sprague-Dawley rats (n = 40) were subjected to photothrombotic infarction. Three days after photothrombotic infarction, rats were randomly allocated to one of four experimental groups (IA group: n = 12, IV group: n = 12, superparamagnetic iron oxide (SPIO) group: n = 8, control group: n = 8). All groups were subdivided into 1-, 6-, 24-, and 48-hour groups according to time point of sacrifice. MR images of rat brain were obtained prior to and at 1, 6, 24, and 48 hours postimplantation. After final MRI, rats were sacrificed and grafted cells were analyzed in brain and lung specimen.
Results
Grafted cells appeared as dark signal intensity regions at the infarction. In IA group, dark signals in infarction were more prominent compared with IV group. On Prussian blue staining, IA administration showed substantially increased migration and a large number of transplanted hBMMSCs in the target brain than IV administration.
Conclusion
IA transplantation results in superior delivery and sustained presence of hBM-MSCs in 48-hour group (five days after brain infarction) compared to IV transplantation.

Signal Intensity of Normal Facial Nerves on Post-Contrast T1-Weighted Images at 3T: Comparison of 2D and 3D Pulse Sequences

Haneda, J.[1]·Ishikawa, K.[2]·Okamoto, K.[3]·Sato, T.[1]
[1]Nagaoka Chuo General Hospital, Nagaoka, JAPAN, [2]Niigata University, Niigata, JAPAN, [3]Brain Research Institute Niigata University, Niigata, JAPAN.

Purpose
Magnetic resonance imaging (MRI) is an important tool for investigating diseases affecting facial nerves. Recently, 3T MRI has become common in our daily clinical practice and proper sequences must be selected. Gradient echo-based 3D T1WIs commonly are used and have less partial volume effect with thinner slices than 2D T1WI. However, gradient echo-based 3D T1WIs show susceptibility artifacts due to mastoid pneumatization, which may impede visualization of the facial nerves. We visually compared the signal intensity of normal facial nerves on 3D T1WI with that on conventional 2D T1WI.
Materials & Methods
We retrospectively reviewed 124 normal facial nerves of 62 patients, including 32 patients(21 men, 11 women; mean age, 52.72 years) with postcontrast 3D T1WI and 30 patients(12 men, 18 women; mean age, 50.03 years) with postcontrast 2D T1WI obtained at our hospital from 2009 to 2012. Cases with clinical facial palsy, cerebello-pontine angle tumor, and a past history of intracranial surgery or radiation therapy were excluded in this study. MR imaging was performed on a 3T imager(Magnetom Verio, Siemens) with a 32-channel head coil. Spin-echo T1WI(slice thickness, 3mm; slice gap, 0mm) and fast low angle shot(FLASH) (slice thickness, 1mm; slice gap, 0mm) were used for 2D and 3D T1WI, respectively. Two radiologists evaluated the signal intensity of the facial nerves in agreement using a 4-scale visual score as follows: 1, hypointense to temporal gray matter; 2, isointense to temporal gray matter; 3, isointense to temporal white matter; 4, hyperintense to temporal white matter in the same plane. Visual scores were examined by two radiologists in the five facial nerve segments as follows: the intrameatal segment (Im), labyrinthine segment (Lb), geniculate ganglion (GG), horizontal segment (Hz) and vertical segment (Vt). We compared the visual scores in each segment on 3D T1WI with those on 2D T1WI via relative to an identified distribution (RIDIT) analysis.
Results
Visual scales in each segment on 2D T1WI and 3D T1WI are shown in Table 1. The scores in the Im, Lb, and GG on 3D-T1WI were significantly higher than those on 2D T1WI (P<0.01 for each segment), whereas the scores in the Hz on 3D T1WI were significantly lower than those on 2D T1WI (P<0.01). There were no significant differences between the scores in the Vt on 3D T1WI and 2D T1WI. Image quality was adequate for diagnosis.
Table 1. Visual scale results on 2D T1WI and 3D T1WI for each normal facial nerve segment

	Im		Lb		GG		Hz		Vt	
scale	2D	3D	2D	3D	2D	3D	2D	3D	2D	3D
1	0	0	6	1	8	0	5	53	1	0
2	12	0	30	0	0	3	6	9	0	0
3	44	20	23	39	18	7	37	2	2	0
4	4	44	1	24	34	54	12	0	57	64

Conclusion
The signal intensity of the facial nerve was higher on Gd-enhanced 3D T1WI compared to that on Gd-enhanced 2D T1WI in the Im, Lb, and GG segment, but the intensity of

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

that in the Hz segment was higher on 2D T1WI than that on 3D T1WI.

Subfrontal Neuroendoscopic Approach to the Anterior Wall of the Third Ventricle: An Applied 3T MR Imaging Morphometric Study

Matys, T.[1]·Horsburgh, A.[1]·Kirollos, R. W.[1]·Antoun, N.[1]·Massoud, T. F.[2]
[1]Addenbrooke's Hospital, Cambridge, UNITED KINGDOM, [2]University of Cambridge, Cambridge, UNITED KINGDOM.

Purpose
Detailed neuroimaging analysis can be critical for accurate characterization of regional anatomy of the anterior third ventricle, an area of substantial neurosurgical importance. The lamina terminalis (LT), the main structure in the anterior third ventricular wall, can provide an access window for removal of intraventricular tumors, and may be fenestrated during treatment of aneurysmal subarachnoid hemorrhage to prevent ensuing hydrocephalus. More recently, neuroendoscopic opening of the LT via the subfrontal supraorbital approach has been suggested as an advantageous alternative to conventional third ventricular floor fenestration in internal shunting of obstructive hydrocephalus. The anatomy of this anterior third ventricle region has been studied previously on cadavers; this however requires organ fixation and is potentially prone to shrinkage errors. In this study we use high-resolution 3T MRI to obtain more accurate in vivo morphometric measurements of the anterior third ventricular structures of relevance to subfrontal neuroendoscopy.
Materials & Methods
We retrospectively analyzed magnified midsagittal T1-weighted 3T MR images of 50 patients (25 men and 25 women) with normal brain imaging findings, with a mean age of 49 years (range 19-82 years). We measured the following: distances from the frontal pole to the recommended site of fenestration of LT in its inferior third (FP-LT) and to the genu of the corpus callosum (FP-CC), length of LT (LLT), width and depth of the optic recess (ORW and ORD), width and height of the anterior commissure (ACW and ACH), distances from the optic chiasm to the anterior commissure (OC-AC), mammillary bodies (OC-MB) and posterior commissure (OC-PC), and distance between the LT and mammillary bodies (LT-MB). We statistically determined potential correlations between morphometric categories, and age- and sex-related changes in these parameters using Pearson's correlation.
Results
Morphometrics for the various distances are shown in the Table. There were no significant age- or sex-related changes in these measurements. Except for the obvious correlation between LLT and OC-AC (r=0.661, p<0.001), there was only a weak positive correlation between LLT and FP-CC (Pearson's r = 0.601, p<0.01), but not with any of the other measured parameters. The flow voids of the anterior cerebral/anterior communicating artery complex were invariably seen adjacent to the optic chiasm and lower third of the LT. However, components of this complex and their spatial relationships were not unraveled with any confidence on these standard midsagittal images alone.

Parameter	Mean ± SD (mm)	Min-Max (mm)
FP-LT	58.4 ± 4.4	49.8-67.7
FP-CC	35.8 ± 4.7	27.1-45.8
LLT	11.1 ± 1.5	7.8-14.1
ORW	2.9 ± 0.7	1.7-4.3
ORD	3.3 ± 0.9	1.4-4.8
ACW	2.7 ± 0.5	1.7-3.9
ACH	2.9 ± 0.6	1.6-4.0
OC-AC	8.9 ± 1.0	6.9-11.4
OC-MB	7.4 ± 1.1	5.4-9.3
OC-PC	27.7 ± 1.7	24.4-31.5
LT-MB	10.7 ± 1.1	8.4-12.8

Conclusion
We provide the first detailed in vivo morphometric analysis of the anterior third ventricular region, including the distance of the LT to the frontal poles. These baseline data are relevant and useful for accurate MRI planning of neuroendoscopic and neurosurgical procedures in this region.

P-77

Extraoccular Muscle Morphometrics Relative to Anthropometric Features: Evaluation of Potentially Novel MR Imaging Indices for Assessing Graves' Ophthalmopathy

Wing, L.[1]·Matys, T.[1]·Horsburgh, A.[1]·Antoun, N.[1]·Massoud, T. F.[2]
[1]Addenbrooke's Hospital, Cambridge, UNITED KINGDOM, [2]University of Cambridge, Cambridge, UNITED KINGDOM.

Purpose
Thyroid orbitopathy is the most common extathyroidal manifestation of Grave's disease. MRI is useful for studying edematous swelling and fibroblast proliferation within thickened extraoccular muscles (EOMs: IR, MR, SR, LR) that form part of the Graves' ophthalmopathy (GO) spectrum. Amongst several MRI parameters, cross-sectional areas of EOMs, used as valid surrogates for EOM volumes, have been regarded as useful simple variables for diagnosis and monitoring the course of GO treatment. It was shown

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

previously that normative morphometrics of the EOMs poorly correlate with age and sex alone, but no prior studies have factored in the potential variation in dimensions of normal and dysythyroid EOMs with patient anthropometric features (AFs). In this feasibility study we initially obtained detailed morphometrics of EOMs in normal and GO patients. We then tested the hypothesis that correlation with several patient AFs would result in more refined imaging indices for GO than possible without factoring in individual patient variations in dimensions of orbits and heads.

Materials & Methods

We retrospectively evaluated 102 standard multiplanar MRI studies of the orbits and brain (i.e., 204 orbits), 52 in patients with GO and 50 with normal findings. An observer blinded to clinical data and using electronic calipers manually traced and measured cross-sectional area at maximum belly thickness for each rectus muscle on coronal T2WIs. We then recorded seven AFs on each study on axial and coronal images: interzygomatic distance, biparietal distance, fronto-occipital distance, orbital width, orbital depth, greatest orbital height, and greatest horizontal ocular diameter, bilaterally when required. We statistically correlated rectus muscle areas and AFs using unpaired t-test and Pearson's correlation coefficient (significance set at p-value <0.05).

Results

The GO group (M:F=13:39) had a mean age 57.8 years; the control group (M:F=22:28) had a mean age 46.6 years. Age and sex did not statistically influence muscle size or AFs. There was no significant difference between AFs of patients in GO and control groups. Mean cross-sectional areas of rectus muscles in the GO group were: IR=55.3mm^2, MR=43.0mm^2, SR=40.2mm^2, and LR=25.9mm^2. Mean cross-sectional areas of rectus muscles in the control group were IR=25.1mm^2, MR=27.0mm^2, SR=22.5mm^2, and LR=17.3mm^2. All rectus muscles were significantly larger in the GO group compared to control group (P<0.0001). There was no significant correlation between each AF and the combined rectus muscle area in either group. Therefore, combined rectus muscle cross-sectional area was 1.79-fold greater in the GO group, and when this was divided by each AF, the ratios similarly ranged from 1.54- to 1.82-fold higher in the GO group compared to the controls.

Conclusion

This is the first study investigating variation in sizes of the EOMs with AFs. In adults, the size of EOMs, whether in normal patients or in those affected by GO, did not statistically correlate with the AFs, as similarly established previously for other independent factors such as age and sex. Potentially new indices derived in this study for characterizing rectus muscle size relative to AFs in patients with GO did not confer any advantage over measuring muscle morphometrics alone.

Accuracy of Coronal Contrast-Enhanced Fat-Suppressed FLAIR in Detecting Acute Optic Neuritis and Its Sequela

Iyer, V. R.·McKinney, A. M.·Rykken, J. B.
University of Minnesota
Minneapolis, MN.

Purpose

Optic neuritis (ON), remains a clinical diagnosis, in which brain/orbital MRI is primarily utilized to detect brain lesions or to exclude other orbital pathology. Axial FLAIR images have been found to have higher specificity but lower sensitivity than contrast-enhanced T1-weighted images (T1WI), the current imaging standard, in detecting acute optic neuritis (ON). By using newer FLAIR techniques, detection of acute ON or its sequela, may be improved. The purpose of this study is to determine the accuracy of coronal contrast-enhanced fat-suppressed FLAIR (CE-FS-FLAIR) images in detecting ON.

Materials & Methods

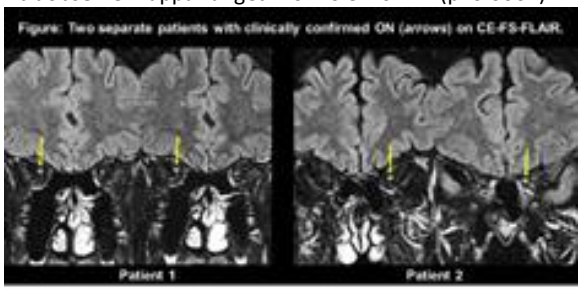
Internal review board approval was obtained. The clinical data and MRI examinations of 44 patients who underwent 1.5T brain MRI to rule out or evaluate demyelinating disease, which included a CE-FS-FLAIR sequence, were reviewed retrospectively. Each patient underwent 3mm coronal CE-FS-FLAIR as part of a new "Multiple Sclerosis brain" protocol at our institution over a two-year period. Two staff neuroradiologists independently evaluated the CE-FS-FLAIR sequence, recording "+", "-", or "+/-" (indeterminate) for abnormality of each of the 44 patients' optic nerve (for a total of 88 nerves); these images were reviewed twice by each reviewer at different sittings. These results were correlated with the clinical history of ON in each optic nerve.

Results

There were 15 controls without demyelinating disease or ON, 26 patients suffering a demyelinating disease (10 of

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

whom suffered ON), and three patients with ON but no demyelinating disease. Thus, 31 patients did not have any history of ON, while 13 patients were clinically positive for ON, affecting 19 of the study's 88 optic nerves. Between reviewers, the sensitivity ranged from 74-100%, specificity from 75-93%, and the overall accuracy 80-91%. The PPV was 52.8-73.7%; the NPV was 91.4-100%. The reviewers called "+/-" (indeterminate) in 5-8/88 optic nerves, typically when the fat suppression was compromised near the orbital apex. Interobserver kappa was 0.59 ($p<0.0001$). Intraobserver kappa ranged from 0.54-0.741 ($p<0.0001$).



Conclusion
Coronal CE-FS-FLAIR images are relatively accurate in determining ON, with a particularly high NPV. This sequence could be an adjunct to postcontrast, fat-suppressed T1WI in evaluating ON patients with suspected demyelinating disease. However, it would be optimal for future studies to directly compare CE-FS-FLAIR to T1WI, and to compare both sequences to the clinical data, both in patients suffering demyelinating disease as well as in controls.

MR Imaging of Fasciocutaneous and Myocutaneous Flap Reconstruction following Orbital Exenteration

Sedrak, P.[1]·Lee, P. S.[1]·Guha-Thakurta, N.[2]·Chang, E. I.[2]·Ginsberg, L. E.[2]·Esmaeli, B.[2]·Debnam, J. M.[2]
[1]The University of Texas at Houston, Houston, TX, [2]The University of Texas M. D. Anderson Cancer Center, Houston, TX.

Purpose
Complex free flap reconstruction may be performed following orbital exenteration for the treatment of tumors involving the orbit. The purpose of this study was to review the MR imaging findings of fasciocutaneous and myocutaneous flap reconstructions in this patient population.
Materials & Methods
The patient demographics and MR imaging findings of 28 patients who underwent fasciocutaneous or myocutaneous flap reconstruction following orbital exenteration were reviewed retrospectively. The soft tissue or muscular component of the flaps was assessed for enhancement pattern, T2 signal intensity, and size of the flap on initial postoperative and follow-up imaging.
Results
Twelve fasciocutaneous flaps were placed in 12 patients (6 men and 6 women), age range 5-75 years (median 50 years) and 16 myocutaneous flaps were placed in 16 patients (10 men and 6 women), age range 16-78 years (median 48.5 years). The type of orbital flap reconstruction included anterolateral thigh (ALT) (n = 13), radial forearm (n = 7), rectus abdominis (n = 5), deep inferior epigastric perforator (DIEP) (n = 1), serratus anterior (n = 1), and latissimus dorsi (n = 1). The soft tissue component of the fasciocutaneous flaps enhanced in 11 of the 12 cases and was either homogeneous (n = 5) or patchy (n = 6). The enhancement decreased over time in 5 of 10 flaps on followup. Eleven of 12 fasciocutaneous flaps were T2 hyperintense, and nine of 10 flaps that were assessed on follow-up studies decreased in size over time. The enhancement of the muscular component of the myocutaneous flaps was either homogeneous (n = 5), patchy (n = 5), linear (n = 4), or none (n = 2); this decreased over time in six flaps. On T2, the flaps were hyperintense (n = 15) or isointense (n = 1). Three of the 16 flaps decreased in size over time.
Conclusion
The soft tissue and muscular components of fasciocutaneous and myocutaneous orbital flaps are usually T2 hyperintense and demonstrate at least some degree of enhancement after surgery. This enhancement may persist or decrease over time. The soft tissue associated with fasciocutaneous flaps on initial imaging is likely to retract secondary to resolution of postoperative changes such as edema. Neuroradiologists, surgeons and oncologists involved in the care of patients following orbital exenteration with flap reconstruction should become familiar with the imaging findings of these complex flap reconstructions at baseline and on follow-up evaluations.

CT and MR Imaging Patterns of Chordoma and Chondrosarcoma of the Skull Base and Spine before and after Treatment with Proton Beam Radiation

Wycliffe, N. D.·Holness, S.·Suarez, K.·Oyoyo, U.·Loredo, L.·Kido, D.
Loma Linda University Medical Center
Loma Linda, CA.

Purpose
The purpose of this study was to identify CT and MR imaging patterns, frequency of location and the effect of location on the success rate of surgical resection and proton beam radiation treatment for chordoma and chondrosarcoma of the skull base and spine.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Materials & Methods
This study is IRB and HIPPA compliant. This is a retrospective review of all the available CT and MR imaging of cases of chordoma and chondrosarcoma treated at our Proton Beam Radiation Treatment Facility at Loma Linda University Medical Center from January 1, 1992 to June 30, 2011. CT and MR of 424 cases of chordoma and 190 cases of chondrosarcoma were reviewed by two medical students and one CAQ certified neuroradiologist. Tumor location, preoperative, postoperative and post-treatment size of the tumor, presence of calcification in CT, T2 brightness in MRI and contrast enhancement pattern were recorded. Tumor type, location, initial tumor size, postoperative and post-treatment tumor size were correlated to survival data during the study period.
Results
Patient population included 255 males and 169 females with chordoma (age 2-85 years, mean 48.2 years) and 108 males and 82 females with chondrosarcoma (age 8-83 years, mean 45.5 years). During the study period alive:dead:lost to follow-up numbers for chordoma were 216:173:35 and chondrosarcoma 114:52:24. Chordoma had higher prevalence in skull base (SB) 36.76%, cranio-cervical junction (CCJ) 19.6%, cervical spine (CS)16.18% and sacro-coccygeal spine (SCS)16.67% than thoracic (TS) 3.92% and lumbar spine (LS) 6.86%. Chondrosarcoma had higher prevalence in skull base 65.22% and thoracic spine 21.74% than cranio-cervical junction 3.26%, cervical spine 3.26%, lumbar spine 2.17% and sacro-coccygeal spine 4.35%. Significant imaging features: for chordoma were, midline 67.66%, heterogeneous T2 hyper intensity 69.7%, no clacification70.6%, heterogeneous contrast enhancement 96%, and for chondrosarcoma were, off midline 80.2%, calcification 59.74%, contrast enhancement 98.5% (16.6% homogeneous). Death rates were higher with chordoma compared to chondrosarcoma in SB (31% vs.15.4%), CCJ(16.7% vs.7/7%), CS(31% vs.7.7%) and LS(14.3% vs.0%) and death rate was higher for Chondrosarcoma compared to Chordoma in TS(69.2% vs.7.1%). Positive correlation was seen with higher preoperative, post operative and post treatment tumor volume in both CT and MRI and death during the study period compared to those who were alive. Patients in the alive category showed increased reduction of tumor volume in the postoperative and post-treatment scan compared to those who died, for chordoma in SB, CCJ, and CS and in postoperative scan for chondrosarcoma in SB and TS. For chordoma, mean postoperative tumor resection volumes were higher in SB and CS compared to CCJ. Post-treatment tumor volume was difficult to assess in the spine for metallic hardware related artifacts.
Conclusion
Imaging characteristics overlap between chordoma and chondrosarcoma in the skull base and spine; however location, calcification and enhancement pattern are helpful in differentiating them. Higher reduction of tumor volume in postoperative scans show positive correlation with increased reduction of tumor volume in postproton beam radiation treatment scans and longer survival. Postsurgical tumor volume reduction was proportionately lower in CCJ compared to SB and CS in our study.

P-81

Head and Neck Imaging of Chronic Recurrent Multifocal Osteomyelitis

Sargar, K.·Kao, S.·Sato, Y.·Ferguson, P.·Singh, A.
University of Iowa Hospitals
Iowa City, IA.

Purpose
1. To demonstrate various imaging features of chronic recurrent multifocal osteomyelitis (CRMO) in head and neck region. 2. To discuss key imaging features to differentiate CRMO from other differential diagnoses such as infection and neoplasms.
Materials & Methods
Chronic recurrent multifocal osteomyelitis is noninfectious osteomyelitis seen in pediatric population. Most common sites of involvement are metaphysis of long bones, clavicle, mandible, vertebrae and pelvis. Typical imaging pattern of involvement in clavicles and mandible is very helpful for the diagnosis of this entity. Though extremity involvement is common in CRMO, involvement of clavicles and mandible is important differentiating point between CRMO and infection. We are demonstrating radiographic, MRI, CT and nuclear scan imaging features of two prototype sites of CRMO (i.e., clavicles and mandibles). There are two phases of CRMO - active and reparative. Imaging appearance can also be helpful to suggest the phase of disease. Lack of abscess, fistula sequestrum and significant soft tissue involvement and aggressive periosteal reaction are key features to differentiate CRMO from infectious osteomyelitis and neoplasms.
Results
Though CRMO is diagnosis of exclusion, radiologists can suggest diagnosis based on imaging appearance. It is necessary to differentiate CRMO from infections and neoplasms as treatment approach and prognosis is entirely different.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Conclusion
CRMO is noninfectious osteomyelitis in pediatric population with typical involvement of clavicles and mandibles in head and neck region. Various key features on imaging of head and neck region are helpful to differentiate chronic recurrent multifocal osteomyelitis from infection and neoplasms. Differentiation of CRMO from these entities is essential in view of treatment and prognostication.

Cervical Lymph Node Metastasis from Papillary Thyroid Carcinoma: Spectrum of Ultrasonographic Findings

Kumar, S.[1]·Edeiken-Monroe, B. S.[2]·Debnam, J. M.[2]
[1]Baylor College of Medicine, Houston, TX, [2]The University of Texas M. D. Anderson Cancer Center, Houston, TX.

Purpose
Knowledge of the presence of cervical lymph node metastasis in papillary thyroid carcinoma is imperative for appropriate management. The purpose of this study was to evaluate the ultrasonographic (US) appearance of metastatic cervical adenopathy in the setting of papillary thyroid carcinoma (PTC).
Materials & Methods
The clinical data, imaging studies, and US-guided biopsy results from lymph node metastasis in patients with PTC were reviewed retrospectively. Inclusion criteria included an US of the soft tissues of the neck and accompanying US-guided fine needle aspiration (FNA) biopsy documenting metastatic cervical adenopathy. The indication for US imaging, appearance of the metastatic lymph nodes including degree of vascular flow and the presence calcification, and the treatment were reviewed.
Results
Cervical lymph node metastasis is associated with primary and recurrent PTC. Lymph nodes of concern are detected during clinical examination, US examination for thyroid nodules, and during evaluation of abnormal lymph nodes incidentally detected on alternate imaging modalities and routine surveillance following thyroidectomy. The metastatic lymph nodes are hypoechoic with distortion or absence of the normal central fatty echogenic hilum. Disorganized vascular flow, punctate calcification and a cystic component may be present raising concern for metastasis. Reactive lymph nodes cannot be distinguished from metastatic adenopathy based on US characteristics and thus, US-guided FNA is required for diagnosis. Surgical resection often is performed on documented pathologic lymph nodes in the soft tissues of the neck.
Conclusion
Cervical nodal metastases from PTC should be suspected in the presence of alteration or absence of the central echogenic hilum, distortion of the normal hilar vascularity, calcification and cystic change. An US-guided FNA is necessary to document metastasis and to facilitate presurgical planning.

Bump on the Forehead: The Differential Diagnosis of Pott's Puffy Tumor

Espinoza, F. V.·Castillo, M.
University of North Carolina
Chapel Hill, NC.

Purpose
The classic description of Pott's puffy tumor is that of a patient presenting with a bump on the forehead due to chronic osteomyelitis of the frontal bones due to underlying frontal sinus infection. This presentation is not unique to this condition and imaging becomes essential for finding a specific etiology. Illustrative cases are presented to demonstrate the range of conditions that present with forehead bumps. We provide a differential diagnosis, and discuss their complications.
Materials & Methods
Examples of diverse conditions presenting as forehead lumps from our teaching files (2002-2012) using both MRI and CT were chosen. Each entity was reviewed and a differential diagnosis generated. Complications from these entities are addressed.
Results
A review of the case files has shown that many categories

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

of disease including infection (tubercular, pyogenic), traumatic, tumor, inflammatory (mucocele, polyposis) and vascular as well as developmental anomalies (encephaloceles, dermoids) can present as a bump on the forehead. Diagnostic imaging provides the necessary information to differentiate among these and triage the patient to the correct treatment. Imaging is also helpful in the evaluation of complications arising from these entities.
Conclusion
Patients presenting with Pott's puffy tumor or a forehead bump should undergo CT and possibly MRI to determine the nature of the lesion and choose the appropriate treatment. Evaluation of the underlying bone and frontal sinus is indispensable as many entities arising in them present with bump on the forehead.

KEYWORDS: Abscess, Masses, Pott's puffy tumor

Usefulness of High-Resolution Three-Dimensional Diffusion-Weighted Imaging of Middle Ear Cholesteatoma: Compared to Single-Shot Echo-Planar Diffusion-Weighted Imaging

Yamashita, K.[1]·Yoshiura, T.[1]·Hiwatashi, A.[1]·Obara, M.[2]·Togao, O.[1]·Matsumoto, N.[1]·Kikuchi, K.[1]·Honda, H.[1]
[1]Kyushu University, Fukuoka, JAPAN, [2]Philips Electronics Japan, Tokyo, JAPAN.

Purpose
To prospectively evaluate the usefulness of a newly developed high-resolution three-dimensional diffusion-weighted imaging method, turbo field-echo with diffusion-sensitized driven-equilibrium (DSDE TFE) in diagnosing middle-ear cholesteatoma by comparing it to conventional single-shot echo-planar diffusion-weighted imaging (SS EP DWI).
Materials & Methods
Institutional review board approval and informed consent from all participants were obtained. We studied 30 patients with preoperatively suspected acquired cholesteatoma. Each patient underwent an MR examination including both SS EP DWI and DSDE TFE using a 3.0 T MR scanner. Images of the 30 patients (60 temporal bones including 30 with and 30 without cholesteatoma) were reviewed by two independent neuroradiologists. The confidence level for the presence of cholesteatoma was graded on a scale of 0-2 (0 = none, 1 = equivocal, 2 = definite). Interobserver agreement as well as sensitivity, specificity, and accuracy for detection were assessed for the two reviewers.
Results
Excellent interobserver agreement was shown for DSDE TFE ($\kappa = 0.821$) whereas fair agreement was obtained for SS EP DWI ($\kappa = 0.416$). Turbo field-echo with diffusion-sensitized driven-equilibrium was associated with significantly higher sensitivity (83.3 %) and accuracy (90.0 %) compared to SS EP DWI (sensitivity = 35.0 %, accuracy = 66.7 %; $p<0.05$). No significant difference was found in specificity (96.7 % for DSDE TFE, 98.3% for SS EP DWI).
Conclusion
With increased spatial resolution and reduced susceptibility artifacts, DSDE TFE improves the accuracy in diagnosing acquired middle ear cholesteatomas compared to SS EP DWI.

KEYWORDS: Cholesteatoma, Diffusion-weighted imaging, 3D

Usefulness of Contrast-Enhanced 3D T1 VISTA for Diagnosis of Facial Neuritis: Compared with Contrast-Enhanced T1 Turbo Spin-Echo Imaging

Ryu, C.[1]·Choi, W.[1]·Jahng, G.[2]·Lee, K.[1]
[1]Kyung Hee University Hospital, Seoul, KOREA, REPUBLIC OF, [2]Kyung Hee University Hospital at Gangdong, Seoul, KOREA, REPUBLIC OF.

Purpose
Three-dimensional reformatted images are promising technique. It offers improved anatomical accuracy with minimal flow artifact and thinner sections without gaps between slices when compared with conventional 2D imaging. The purpose of this study was to evaluate the usefulness of the contrast-enhanced 3D T1-weighted VISTA fat-suppression (CE T1 VISTA) sequence when compared to contrast-enhanced T1-weighted turbo spin-echo images (CE T1 TSE) sequence in patients with facial neuritis.
Materials & Methods
The study enrolled 32 consecutive patients (21 females, mean age: 52.4 years ± 13.6, 25 right lesions) who underwent internal auditory canal (IAC) MR imaging for Bell's palsy. Internal auditory canal MR scanning including CE T1 VISTA and CE T1 TSE and was performed in all patients by use of 3T scanner. Scan order of CE T1 VISTA and CE T1 TSE were performed randomly. Contrast-enhanced T1 VISTA was performed with the following parameters: TR, 350 ms; TE, 19.51 ms; matrix, 360 x 299; field of view, 113 x 180; section thickness, 1 mm; total scan time, 3 min 4 sec. Parameters of CE T1 TSE are as follow: TR, 568.82 ms; TE, 11.00 ms; matrix, 256 x 205; field of view, 180 x 200; section thickness, 2 mm; total scan time, 3 min 36 sec. The signal intensity was measured from three segments (canalicular, labyrinthine, and anterior genu) of the facial nerve by drawing ROI along the affected side and normal side in each segment. We compared quantitative lesion-to-normal contrast ratio of two MR sequences with paired t-test.
Results
In all three segments, the lesion-to-normal contrast ratios on CE T1 VISTA (canalicular: 2.22 ; labyrinthine: 2.02 ; anterior genu: 1.99) were greater than those on CE T1 TSE (canalicular: 2.17 ; labyrinthine: 1.72 ; anterior genu: 1.68). Labyrinthine and anterior genu segment were significantly

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

higher lesion-to-normal contrast ratios on CE T1 VISTA SPAIR in patients with facial neuritis (labyrinthine: P= 0.030; anterior genu: P = 0.004).
Conclusion
Contrast-enhanced T1 VISTA was significantly superior to CE T1 TSE regarding image contrast between lesion and normal facial nerve. By using CE T1 VISTA image, diagnostic performance of facial neuritis can be improved.

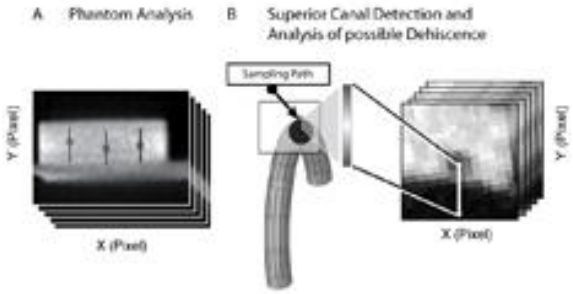
Novel Method of 3D Image Analysis of High-Resolution Cone-Beam CT and Multislice CT for the Detection of Semicircular Canal Dehiscence

Eibenberger, K.[1,2,3]·Carey, J. P.[2]·Ehtiati, T.[4]·Trevino, C.[2,5]·Haslwanter, T.[1]
[1]University of Applied Sciences Upper Austria, Linz, AUSTRIA, [2]Johns Hopkins University School of Medicine, Baltimore, MD, [3]Johannes Kepler University, Linz, AUSTRIA, [4]Siemens Corporation, Baltimore, MD, [5]Escuela de Medicina Ignacio A. Santos, Monterrey, MEXICO.

Purpose
In semicircular canal dehiscence (SCD), multislice CT (MSCT) scans tend to overestimate the size of dehiscence and skew the ascertainment toward dehiscence when thin bone may remain; therefore we present an objective method to detect inhomogenities in temporal bones, based on comparison of radiodensity variance in regions of interest (ROIs).
Materials & Methods
We simulated the problem of detecting a dehiscence in the superior canal (SC) by building a bone cement phantom containing holes(0.4-0.1mm). In addition, a cadaveric head specimen was used to create an anatomical model for a "borderline" SCD: a middle fossa craniotomy was performed and the SC was drilled to the point of translucency. Tomographic scans were acquired on MSCT(Toshiba Aquilion64, step-mode, 0.5mm collimation, 135kVp, 250mA) and cone-beam CT (CBCT) with high-resolution secondary reconstructions (HR CBCT, Siemens Artis zee C-Arm-syngo HR-Dyna CT, 89kVp, 140mA, 20s scan time, 1x1 binning prototype). Variances of radiodensity in bone cement ROI scans containing a hole were compared with variances in regions without holes(Figure A). This technique was applied to detect the artificial dehiscence on the cadaveric head: we collected radiodensities from a row of 30 voxels along a path from the lumen of the SC orthogonally out toward the middle cranial fossa. This linear ROI was compared with a spherical ROI covering only the lumen of the SC(Figure B). Variance of radiodensity in each ROI was compared with the Fligner-Killeen test. Dehiscence(absence of bone) was rejected if the variances were not different (p≥0.05).
Results
Holes in bone cement and intact bone over the SC was detected by comparing the homogeneity of variance. HR CBCT, CBCT and MSCT detected a hole in bone cement<0.1mm (p=0.0001 for 0.1mm, HR CBCT). For thin bone over the cadaveric SC, the method rejected the existence of dehiscence with p=0.6922 with HR CBCT.



Conclusion
We have shown that with CT an approach comparing radiodensity variance in ROIs is capable of detecting a 0.1mm hole in dense, homogeneous bone. If the variance in radiodensity along a path from the center of the canal to the outside exceeds the variance found inside the lumen, then it is likely that some bone remains over the canal, and dehiscence can be rejected. Moreover, this method can be used to objectively compare the spatial resolution of different CT scanners for the problem of SCD. Further clinical evaluation is required to assess the results of this method for correct diagnosis of SCD.

320-Row Multidetector CT Angiography and Digital Subtraction Angiography in the Evaluation of Cerebral Vasospasm after Subarachnoid Hemorrhage

Hebert, J.·Roncarolo, F.·Tampieri, D.·Cortes, M. D. P.
Montreal Neurological Institute
Montreal, QC, CANADA.

Purpose
To determine if 320-row multidetector CT angiography is a reliable technique to assess cerebral vasospasm following subarachnoid hemorrhage by comparing it with the gold-standard DSA.
Materials & Methods
Diameters of 54 arteries were measured retrospectively on both CTA and DSA in eight patients who were diagnosed with cerebral vasospasm following an aneurysmal subarachnoid hemorrhage. Digital subtraction angiography was performed within 24 hours following CTA. Statistical analysis was performed to determine the correlation between the arterial diameters measured by both techniques.
Results
The quantitative approach used in this study to determine the correlation between 320-row MDCT angiography and DSA showed excellent interobserver reliability. There was however no statistically significant correlations between arterial diameters taken on CTA and DSA. CT angiogrqaphy tended to show smaller arterial diameters in the anterior circulation of the circle of Willis when compared with DSA.
Conclusion
The results of this study suggest that 320-row multidetector CT angiography may overestimate the degree of vasospasm in the anterior circulation. The method used by this study, which is unique in that it adopted a quantitative approach, proved to be reliable as suggested by the good interobserver reliability and should be repeated with a greater sample size.

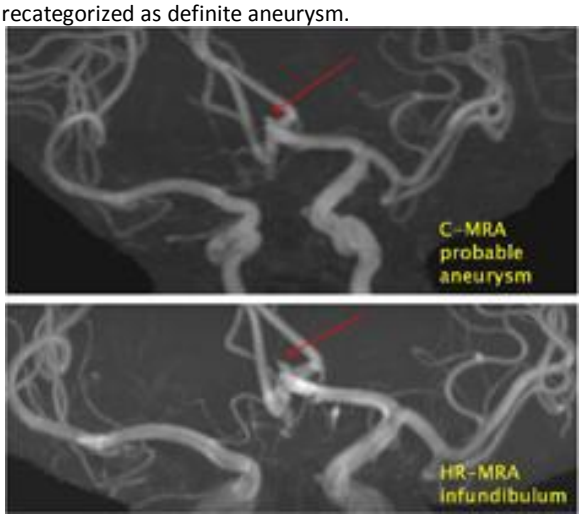
Detection of True Aneurysm Using High-Resolution Time-of-Flight MR Angiography at 3.0T: Correlation with Standard Digital Subtraction Angiography

Lee, A.·Sohn, C.·Han, M.·Yoon, T.·Kang, H.·Jung, S.·Yoo, I.·Kim, S.
Seoul National University Hospital
Seoul, KOREA, REPUBLIC OF.

Purpose
1. To evaluate accuracy of 3T high-resolution MRA in detecting aneurysm compared with conventional MRA. 2. To prove potential diagnostic advantage of high-resolution MRA using correlation with DSA.
Materials & Methods
Thirty-two patients with 43 possible aneurysms on conventional MRA underwent 3T high-resolution MRA and DSA. The protocols of high-resolution MRA were following: TR 29.0, TE 4.6, matrix 512 x 512, FOV 20 cm, and thickness 0.5 mm with 8-channel head coil. Two blinded neuroradiologists reviewed conventional MRA and high-resolution MRA in the detection of aneurysms, independently. For each possible aneurysm, readers recorded the location and their level of confidence with a three point scale (0:no, 1:suspicious, and 2:definite aneurysm). Two dimensional or VR DSA were obtained and used as the standard of reference. The accuracy was calculated in addition to the sensitivity and specificity of high-resolution MRA compared to conventional MRA. In particular, cases with advantage of detection on high-resolution MRA were evaluated in detail.
Results
Digital subtraction angiography revealed 35 aneurysms in 25 patients and no aneurysm or ID in eight cases in seven patients. Multiple aneurysms were 12 cases in eight patients. On high-resolution MRA, reviewers exactly detected 40, 37 cases, superior to conventional MRA (29, 32 cases). On the lesion-based evaluation, accuracy, sensitivity, and specificity of were 89.5%, 91.5, and 81.3% on high-resolution MRA and 72.1%, 81.5%, and 31.3% on conventional MRA, respectively. Each three and five suspicious aneurysm on conventional MRA were recategorized as definite aneurysm.



Conclusion
High-resolution MRA had a high accuracy, sensitivity and specificity for the detection of intracranial aneurysms, comparing conventional MRA. In equivocal aneurysm on conventional MRA, high-resolution MRA can be a useful tool and replace DSA.

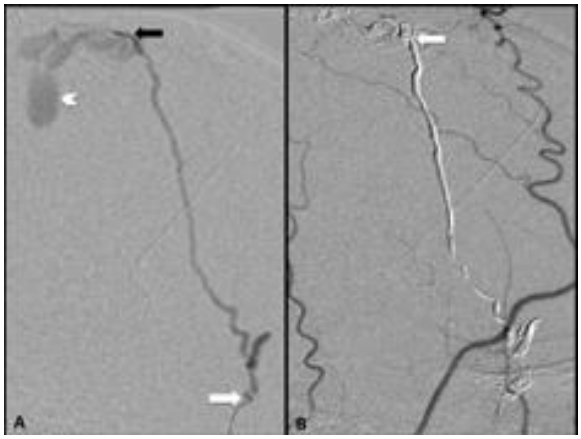
Onyx Embolization of Dural Arteriovenous Fistulas Using a New Dual Arterial Pedicle Catheterization Technique

Miller, T. R.·Gandhi, D.·Jindal, G.
University of Maryland
Baltimore, MD.

Purpose
Embolization of dural arteriovenous fistulas with Onyx (eV3, inc.) has proven to be safe and effective. However, when a microcatheter cannot be navigated distally in the arterial pedicle due to either small vessel size or proximal tortuosity, the standard "plug-and-push" technique of Onyx embolization can be challenging. In these instances, formation of an occlusive plug of Onyx around the microcatheter tip prior to forward flow of the liquid embolic agent is essential to achieving subsequent distal penetration and lesion closure. We present a new technique for forming this crucial plug of Onyx utilizing a second microcatheter navigated alongside the first.
Materials & Methods
A series of cases consisting of four patients with dural arteriovenous fistulas was collected at our institution and one other, all of which had small, and/or, tortuous arterial feeders that prevented distal navigation of the microcatheter to a position close to the fistula. All patients were male, age over 50, who presented over a two-year period. Clinical presentations included pulsatile tinnitus (two) and hemorrhagic stroke (two). All patients had undergone prior fistula treatment using standard Onyx embolization technique, without complete fistula closure. Using the dual arterial pedicle catheterization technique, two microcatheters were navigated into the arterial pedicle of interest. Onyx 34 then was injected via the proximal microcatheter, forming an occlusive plug around the more distal catheter. Fistula embolization then proceeded by injection of Onyx 18 via the distal microcatheter.
Results
Fistula location varied, with one located parasagittally near the vertex, while the remaining lesions were in the posterior fossa. Arterial supply was primarily from external carotid artery branches; two patients also had supply from vertebral artery dural branches. Three fistula had associated cortical venous reflux. In three patients, the dual arterial pedicle catheterization technique resulted in complete obliteration of the fistula. In the fourth patient, the technique resulted in good penetration of the lesion, but there was residual mild arteriovenous shunting from other feeders that has required subsequent treatment.



Conclusion
Our experience demonstrates the utility of using a second microcatheter to form an occlusive Onyx plug proximally in an arterial pedicle prior to dural fistula embolization. This technique appears well suited when working in small, and/or tortuous arterial pedicles. This technique also may prove advantageous in embolization of cerebral arteriovenous malformations under similar circumstances. Further experience is necessary to fully assess the technique's potential for enhancing Onyx embolization of vascular malformations.

Strategy of Endovasucular Treatment for Dural Arteriovenous Fistulas of Cavernous Sinus Using 320-Row Area-Detector Computed Tomography

Kiura, Y.·Okazaki, T.·Sakamoto, S.·Matsushige, T.·Shinagawa, K.·Ichinose, N.·Kurisu, K.
Hiroshima University
Hiroshima, JAPAN.

Purpose
In transvenous embolization (TVE) for cavernous sinus dural arteriovenous fistula (CSdAVF), the main access route to lesion is the inferior petrosal sinus (IPS). However, the IPS often is occluded. In such cases, it is important to know substitute access routes before treatment. As a new imaging modality, 320-row area detector computed tomography (320ADCT) offers a short scan time and superior spatial resolution compared to conventional CT. The aim of this study is to examine an utility of 320ADCT and treatment strategies on CSdAVF.
Materials & Methods
Since July 2010, 320ADCT was obtained in five patients with CSdAVF treated with endovascular treatment. We performed 320ADCT preoperatively and divided results into arterial phase, late arterial phase and venous phase. We then judged the relationships between draining veins

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

and the normal venous system.
Results
Imaging results allowed us to grasp the lengths of the occluded portion of the IPS and the confluence of the IPS and internal jugular vein, helping us to open up the occluded IPS.
Conclusion
Use of 320ADCT angiography helped diagnose CSdAVF and facilitated successful treatment planning.

Spontaneous Thrombosis without Associated Hemorrhage Revealing a Brain Arteriovenous Malformation: A Rare Presentation

Clarençon, F.[1]·Cao, C.[2]·Sourour, N.[1]·Di Maria, F.[1]·Nouet, A.[1]·Reina, V.[1]·Cornu, P.[1]·Chiras, J.[1]
[1]Pitié-Salpêtrière Hospital, Paris, FRANCE, [2]University Hospital of Dijon, Dijon, FRANCE.

Purpose
To detail a rare presentation of brain arteriovenous malformation (bAVM): the thrombosis of the draining vein without subsequent hemorrhage, and to review the literature on this rare occurrence.
Materials & Methods
Brain arteriovenous malformations are serious vascular malformations that may be responsible for intracranial bleeding. One of the main pathomechanism that can lead to bAVM rupture is thrombosis of the main draining vein. Exceptionally, thrombosis of the venous drainage may occur without subsequent hemorrhage and be revealed by headache or neurologic deficit related to venous congestion. The recognition of such “prerupture” stage is of tremendous importance to plan treatment in emergency. A 31-year-old male was attended in our department for severe headache associated with right hemiparesis and slight aphasia. Brain CT scan and MRI showed abnormal vascular network with a huge cortical venous thrombosis. Perivenous edema also was observed. No intracranial hemorrhage was depicted however. The diagnosis of spontaneous thrombosis of the draining vein in a parietal AVM was considered. The DSA confirmed the diagnosis. Endovascular treatment with NBCA injection allowed for a 2/3 exclusion of the nidus volume.
Results
The patient fully recovered from his neurologic deficits. An additional Gamma-knife radiosurgery is planned.
Conclusion
Spontaneous thrombosis of the draining vein may occur without any hemorrhage and reveal bAVM. Neurosurgeons as well as interventional neuroradiologists should be aware of this rare bAVM presentation in order to treat in emergency the malformation before bleeding.

Endovascular Salvage of Intra-Operative Iatrogenic Complications Involving the Internal Carotid Artery Related to Surgery of the Sellar and Parasellar Regions

Griauzde, J.·Chaudhary, N.·Pandey, A. S.·Sullivan, S. E.·McKean, E. L.·Gemmete, J. J.
University of Michigan Health System
Ann Arbor, MI.

Purpose
To present our experience with acute endovascular management of intra-operative complications involving the internal carotid artery (ICA) related to surgery of the sellar and parasellar regions.
Materials & Methods
We retrospectively reviewed the clinical and operative records, imaging, and postoperative course of patients with intra-operative iatrogenic ICA injury related to surgery involving the sellar and parasellar regions. We subsequently reviewed prior reports of similar complications and their management.
Results
In total, four patient cases with iatrogenic operative injury to the ICA were identified. There were three males and one female. The average age was 52 years. Two patients had a pituitary macroadenoma, one had a complex recurrent planum meningioma, and one had a chondrosarcoma with suprasellar extension. In all four cases the tumor was either compressing or surrounding the affected ICA. Two patients had undergone previous operations and had altered anatomy and extensive calcification. Three of the cases presented with acute obvious carotid bleeding in the surgical field and one presented with loss of pulse of the ICA. Three patients underwent emergent placement of Jostent Graftmaster stents (Abbott Vascular; Santa Clara, CA) for repair of their ICA injury. The first patient required subsequent additional stent placement for improved stent to vessel wall apposition and had residual intermittent unilateral blurred vision. A second patient was at his neurologic baseline at followup. A third patient failed stent placement and required ICA sacrifice because of persistent hemorrhage. This patient passed away six days after the procedure. The final patient experienced an intra-operative ICA stroke. This patient was treated with suction thrombectomy using a Penumbra device (Penumbra Inc; Alameda, CA), intra-arterial tissue plasminogen activator (tPA) and ReoPro (Eli Lilly; Indianapolis, IN) followed by Wingspan stent placement (Stryker Neurovascular; Freemont, CA) for persistent vessel narrowing caused by intraluminal tumor invasion or thrombus. The patient’s course was further complicated by intraprocedural in-stent thrombosis, requiring subsequent balloon angioplasty and additional administrations of tPA and ReoPro. The patient needed subsequent emergent craniotomy for subdural and

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

epidural hematomas. At followup, the patient had mild cognitive deficits and difficulty with writing, but was otherwise at his neurologic base line. His craniotomy bone flap has been replaced.

Conclusion

Intra-operative vascular injury involving the ICA from surgery of the sellar and parasellar regions is uncommon, but when it occurs, management must be immediate and definitive to maximize patient survival and minimize morbidity. Endovascular therapies including covered stent placement, suction thrombectomy, and intra-arterial thrombolysis with adjuvant ReoPro have been reported. Our experience supports the viability of these therapies in the acute management of intra-operative ICA injury.

KEYWORDS: Internal carotid artery, Iatrogenic, acute management

P-93

Utility of Temporary Balloon Occlusion Testing in Prediction of Outcomes following Permanent Parent Vessel Sacrifice

Whisenant, J. T.·Derdeyn, C. P.·Cross, D. T.·Moran, C. J.
Mallinckrodt Institute of Radiology
St. Louis, MO.

Purpose

To review the utility of the temporary balloon occlusion (TBO) test as it pertains to prediction of patient outcomes following permanent parent vessel occlusion. Patients often undergo TBO testing as part of the diagnostic workup prior to permanent parent vessel sacrifice. We perform a three-part test that includes intraprocedural neurologic assessment, neuroangiographic evaluation of the adequacy of collateral flow, and 99m-Tc-Bicisate administration during temporary balloon occlusion. Pending the TBO test results, parent vessel occlusion may be performed; and this patient population is at risk for post-parent vessel sacrifice ischemic complications, such as TIA, stroke, and death.

Materials & Methods

Data were reviewed retrospectively from all patients who underwent ICA TBO from March 2002 to December 2011. Patients then were subdivided into those that underwent permanent ICA occlusion and those that did not. Data from those that underwent permanent ICA occlusion were collected over the succeeding six months for the occurrence of three primary outcomes: transient ischemic attack (TIA), ischemic stroke (CVA), and death. In the subgroup of patients with a CVA following the parent vessel occlusion, additional data were collected in the following areas: 1) type of parent vessel sacrifice (open v. endovascular), 2) timing of symptom onset (procedural, early postop, late postop), and 3) type/location of infarct. Based on these factors, a mechanism of the event was postulated (thromboembolic v. hemodynamic).

Results

One hundred fifty ICA TBOs were performed between March 2002 and December 2011. Thirty-six went on to have permanent endovascular or surgical ICA occlusion. In the group that had parent vessel sacrifice, there were the following outcomes: five TIAs (13.9%), six CVAs (16.7%), and three deaths (7.3% - all due to underlying malignancy). Of the nine patients with ischemic complications (i.e., TIA or CVA) after the parent vessel sacrifice, eight had SPECT performed and all eight were normal or had “fixed” defects, seven had angiography performed and six of the seven were interpreted as normal, and all nine had clinical neurologic assessment performed and all nine passed. Of the six patients with CVA, four are postulated to be hemodynamic in etiology, one is postulated to be thromboembolic in etiology, and one is of indeterminate etiology (hemodynamic or thromboembolic).

Timing and Type of Ischemic Stroke Following Parent Vessel Sacrifice

Age	TBO Angio	SPECT	TBO Neuro Exam	Method of Sacrifice	Time Onset of CVA	Mechanism of CVA	Symptoms
78	Not Done	Pass	Pass	Endovascular	early post-op (hours/days)	Hemodynamic/Embolic - single centrum semiovale by CT	Mild RUE weakness
44	Pass	Pass	Pass	Open Surgical	early post-op (hours/days)	Hemodynamic	Mild weakness - complete recovery at later follow up
51	Pass	Not Done	Pass	Endovascular	early post-op (hours/days)	Hemodynamic - Centrum Semiovale	L hemiplegia, R facial droop
64	Fail	Pass	Pass	Open Surgical	early post-op (hours/days)	Hemodynamic - Centrum Semiovale	LUE weakness persistent at f/up 4 months later
86	Pass	Pass	Pass	Endovascular	late post-op (weeks/months)	Thromboembolic - stump	LUE/LLE weakness and L sided neglect
73	Not Done	Pass	Pass	Endovascular	early post-op (hours/days)	Hemodynamic	R hemiplegia, R facial weakness, aphasia

Conclusion

The rate of ischemic stroke following ICA sacrifice in patients who have “passed” TBO testing is higher than expected. The majority of ischemic strokes affected the deep white matter of the centrum semiovale and occurred in the early or late postop period supporting a hemodynamic etiology. The SPECT and angiographic testing appears to be more effective in assessing cortical flow than assessing flow to the deep white matter.

Conscious Sedation versus General Anesthesia: A Comparison of Outcomes for Acute Ischemic Stroke Patients Receiving Endovascular Treatment

Chao, R.·Vachhani, J.·Talkad, A.·Meagher, S.
University of Illinois College of Medicine at Peoria
Peoria, IL.

Purpose

Endovascular treatment of acute ischemic stroke has two options for sedation: general anesthesia (GA) and conscious sedation (CS). General anesthesia immobilizes the patient and allows greater control over the patient’s vitals and pain, while CS is faster and allows neurologic evaluation during the procedure. There are few studies comparing patient outcomes for the use of CS versus GA. The purpose of this study is to compare the clinical outcomes between the two methods of sedation. We

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

hypothesize that there will be no difference in patient outcomes between the two groups.
Materials & Methods
Medical records from a cohort of adult patients who have undergone digital subtraction angiogram (DSA) after acute ischemic stroke since 2009 were examined retrospectively for the type of sedation used and clinical outcomes as measured by National Institutes of Health Stroke Scale (NIHSS) score and a modified Rankin Scale Score (mRS). National Institutes of Health Stroke Scale and mRS scores were collected at admission and at 90-day followup. Other data collected include use of intravenous tissue plasminogen activator (tPA), length of hospital stay, and discharge disposition. Types of intervention include the use of intra-arterial tPA, mechanical thrombectomy, angioplasty, and stent placement. Patients below 18 years of age and those with incomplete documentation were excluded from the study.
Results
Between January 2009 and January 2012, 123 patients underwent DSA for ischemic stroke and met inclusion criteria. Of these patients, 56 received GA and 67 received CS. The GA cohort had a mean admit NIHSS score of 17.68 ± 7.11 and admit mRS of 4.34 ± 0.64. At 90-day followup, the NIHSS score was 3.29 ± 3.43 and mRS 1.86 ± 1.12. The CS cohort had mean admit NIHSS score of 15.56 ± 6.91 and mean mRS of 4.18 ± 0.90. At 90-day followup, the NIHSS score was 3.70 ± 4.74 and mean mRS of 1.71 ± 1.48. There was no statistically significant difference between the GA and CS groups at admission or 90 days.
Conclusion
There was no appreciable difference in outcomes in patients who had GA versus CS while undergoing DSA after ischemic stroke as measured by NIHSS scores and mRS.

Use of Solitaire Retrieval Device in Wake-Up Strokes: Saint Luke's Neuroscience Institute Experience

Akhtar, N.[1]·Holloway, W.[1]·Martin, C.[1]·Rymer, M.[1]·Akhtar, E.[1]·Chakravarthy, V.[2]
[1]Saint Luke's Neuroscience Institute, Kansas City, MO, [2]University of Missouri-Kansas City School of Medicine, Kansas City, MO.

Purpose
Wake-up strokes at Saint Luke's Neuroscience Institute present unique therapeutic challenge and most of them were denied any interventional treatment due to unknown time of onset. We started intervention on wake-up strokes after incorporation of CT perfusion in our stroke treatment algorithm in 2009. The presenting noncontrast CT of the head had to be normal or show changes of ischemia in less than one third of vascular territory. The CT perfusion should be favorable with preserved blood volume and relative preservation of cerebral blood flow. The presenting NIHSS score should be significant as well.
Materials & Methods
Since approval of Solitaire retrieval device by the Federal Drug Administration in the United States we had treated 31 patients since March 2012 with Solitaire device with adjunct intravenous TPA (i/v TPA), intra-arterial TPA (i/a TPA). Out of these 31 patients, nine patients were wake-up strokes involving the anterior circulation. Three patients with wake-up vertebra-basilar strokes were excluded. The average age was 72.6 years (range 39-92 years). There were six males and three females. The average presenting NIHS score was 16.1 (range from 8 to 25). The location of clot was seven in the middle cerebral artery M1/M2, one with T occlusion and one with ICA occlusion. In all cases the Solitaire device was utilized with no i/v or i/a TPA. One patient needed ICA stenting for acute carotid occlusion. Average fluoroscopy time was 21.47 minutes (range 10-47 minutes). Average total procedure time was 73.66 minutes (range 41-180 minutes). Number of passes were nine passes in one patient, four passes in one patient, two passes in one patient and one pass in six patients. The postprocedure TICI score was 2b in one patient and 3 in eight patients. One patient had intracranial hemorrhage (PH2). This patient expired. There was no embolization in uninvolved territories. The average NIHSS score at discharge was 5.44 (range 0-20), excluding two patients who expired. Thirty day Modified Rankin Score (MRS) was two patients expired, five in one patient, and two in three patients, and one in three patients. This shows favorable outcome of Modified Rankin Score of 0-2 in six patients.
Conclusion
In conclusion, wake-up strokes are a challenging group of patients which can be treated if carefully selected. High technical success rate is possible after availability of mechanical retrieval devices like the Solitaire device and adjunct treatment with TPA is not needed in these patients decreasing the risk of complications.

Arrested Pneumatization of Sphenoid Sinus in Children

Penta, M.[1]·Koral, K.[1,2]
[1]University of Texas Southwestern Medical Center, Dallas, TX, [2]Children's Medical Center, Dallas, TX.

Purpose
Arrested sphenoid sinus pneumatization is a relatively common benign developmental variant in children that may occasionally be confused with significant skull base pathology when unrecognized. The purpose of this study is to review the imaging findings of arrested pneumatization of the sphenoid sinus as seen on MRI and describe the frequency of arrested sphenoid sinus pneumatization in children.
Materials & Methods
Institutional review board approval was obtained for this retrospective study. Brain MR examinations of 316 consecutive patients performed in 2012 were reviewed. Patients with presumed abnormalities of bone marrow, skull base surgery, and history of chemotherapy or radiation therapy and examinations without a coronal T2-weighted sequence were excluded. There were 101 patients (58 male) included in the study. The mean age was 8.41 years (0.67-17.37). Presence of arrested sphenoid sinus pneumatization, described as a focus of increased signal with hypointense corticated margins on coronal T2-weighted spin-echo images, was recorded by a pediatric neuroradiologist. When present, the greatest orthogonal dimensions of the arrested sphenoid sinus pneumatization were noted.
Results
Arrested sphenoid sinus pneumatization was present in 16 (15.8%) of the patients. When present, the mean area of the arrested sphenoid pneumatization was 132 mm2 (SD = 219, min-max = 6-798).

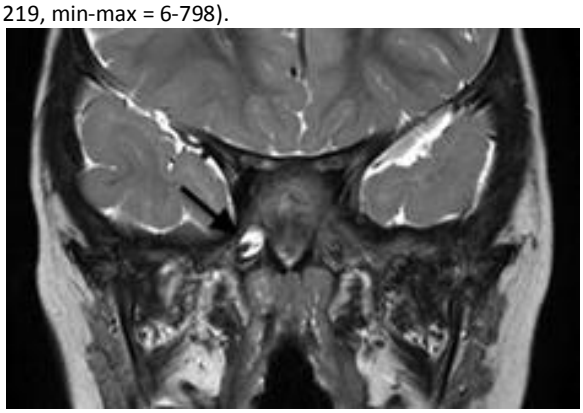

Figure: Coronal T2-weighted image of two-year-old male shows a 8.0 x 4.9 mm delineated T2 hyperintense focus in the right sphenoid body.
Conclusion
Regions of corticated T2 prolongation are seen relatively frequently on normal pediatric brain MR examinations and can be attributed to arrested sphenoid sinus pneumatization. Recognition of this benign developmental variant is important in avoiding unnecessary anxiety, further imaging, and procedures, especially in children with known malignancies.

MR-Guided Laser Ablation of Nonlesional, Nonmesial Temporal Lobe Epileptic Foci in Patients with Medically Refractory Seizures Utilizing Magnetoencephalographic Localization and Surface Electroencephalogram Recording

Ghassemi, A.·Ciricillo, S.·Krishnan, A.·Chez, M.
Sutter Neuroscience Institute
Sacramento, CA.

Purpose
Medically refractory epilepsy affects approximately 300,000 patients in the United States. Early surgery reduces long-term impact and comorbidities, improving quality of life. Fear of an open craniotomy combined with more extratemporal foci in pediatric cases may delay surgical options. Often, as in our series, electroencephalogram (EEG) tracing localization does not correlate with any obvious 3T MRI lesion. We present a less invasive technique, combining EEG, magnetic source imaging (MSI) and functional MR imaging (fMRI) combined with BrainLab localization to enable minimally invasive MRI-guided stereotactic laser ablation (SLA) of epileptogenic foci.
Materials & Methods
Eight medically refractory epilepsy patients (seven to 20 years, median age 12.2 years, Table 1), were evaluated with video EEG, fMRI, MSI and PET and 3T MRI. Six

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

patients had cognitive and behavioral issues making craniotomy for intracranial electrode localization difficult. Three had focal interictal dipole localization that were in regions where traditional surgical intervention would have caused potential collateral damage. Focal abnormalities on EEG were correlated with MSI and PET scan data (Table 1). All underwent SLA (Visualase, Inc.) with frameless navigation (BrainLab, Inc). All had intraoperative EEG monitoring via MR compatible plastic electrodes (Ives) placed over cranial surface above ablated region.

Results

The patients showed resolution (n=7) or diminished number (n=1) of pre-ablation spikes on intraprocedure EEG taken immediately postablation. They were all discharged on postsurgery day one (n=6) or 2 (n=2). To date, the three patients with frontal seizures remained seizure free, off medications, and two have a normal EEG. The dominant posterior temporal patient is seizure free, and the two occipital patients with multiple probes had seizure resolution and EEG normalization. No new visual, cognitive, or motor deficits occurred.

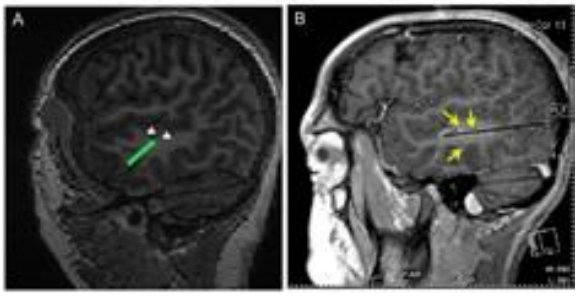

Table 1. Patient Characteristics

Patient #	Age	Sex	MEG Dipole Location	PET Activity	Cognitive Deficit
1	11	M	Left Frontal	N/A	Autism
2	9	M	Right Frontal	N/A	Autism ADHD
3	19	F	Right Middle Temporal Gyrus	N/A	Cognitive Delay Noonan Variant
4	14	F	Right Frontal	N/A	ADHD
5	11	F	Left Inferior Cingulate	Left Inferior Parietal	LD ADHD
6	7	F	N/A	Left Occipital Temporal	Autism Cognitive Delay
7	12	M	Right Occipital Temporal	N/A	Cognitive Delay Autism
8	20	F	Left Superior Temporal	N/A	None

Conclusion

SLA can be an alternative surgical treatment for refractory epilepsy and may allow earlier intervention in temporal or nontemporal cortex foci. Coordinating MSI, fMRI, and surface EEG allows patients to avoid open craniotomy or invasive intracranial EEG electrode placement. Intraoperative laser probe localization via Brainlab guidance permitted accurate ablation of targeted epileptogenic cortex. Surface EEG activity pre- and post-SLA confirmed a decrease in epileptiform discharges.

Abnormal White Matter Microstructure of Posterior Cerebral Tracts Correlates with Sensory Dysfunction, Impaired Multisensory Integration and Inattention in Children with Sensory Processing Disorders

Owen, J. P.·Marco, E.·Fourie, E.·Desai, S.·Harris, J.·Hill, S.·Mukherjee, P.
University of California San Francisco
San Francisco, CA.

Purpose

Sensory processing disorders (SPD) affect 5-16% of school-aged children and cause long-term deficits in intellectual and social development. Current theories of SPD implicate primary sensory cortical areas and higher-order multisensory integration (MSI) cortical regions. The role of white matter in SPD has not been investigated previously. We hypothesize that reduced microstructural integrity of white matter fibers in primary sensory tracts and/or in tracts projecting to multimodal association areas may result in impaired sensory processing, MSI, and motor planning and the inability to suppress distracting stimuli.

Materials & Methods

3T DTI was acquired in 16 boys with SPD and 24 age-, gender-, handedness- and IQ-matched typically developing controls (TDC). All subjects were ages 8-11 years with a full-scale IQ > 70. Auditory, tactile, visual, multisensory, and inattention scores for all subjects were collected using the Sensory Profile, a parent questionnaire. DTI was performed at 2.2 mm isotropic voxel resolution with 64 encoding directions at b=2000 s/mm2. FSL was used to calculate fractional anisotropy (FA), mean diffusivity (MD) and radial diffusivity (RD). Nonparametric permutation testing from tract-based spatial statistics(TBSS) was used to detect significant group differences in the white matter of the whole brain and to detect regions where DTI parameters were significantly correlated with behavioral variables ($p<0.05$, corrected for multiple voxel-wise comparisons).

Results

Significant decreases in FA as well as increases in MD and RD were found in areas of cerebral white matter in the SPD cohort relative to TDC, primarily in posterior white matter tracts including the splenium and posterior body of the corpus callosum, the bilateral posterior corona radiata and the bilateral posterior thalamic radiations, including

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

the optic radiations. Significant positive correlations were observed between FA of specific frontal and posterior cerebral tracts and the auditory, multisensory, and inattention scores (r=0.51-0.78; p<0.001). (See Figure 1 for a representative example.) Conversely, negative correlations were detected between RD and the multisensory and inattention scores (r=0.61-0.71; p<0.001).

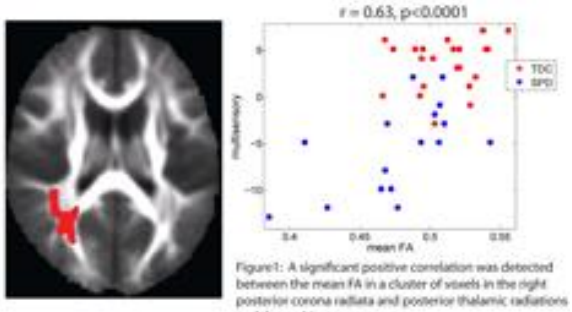

Figure1: A significant positive correlation was detected between the mean FA in a cluster of voxels in the right posterior corona radiata and posterior thalamic radiations and the multisensory score.

Conclusion

We demonstrate reduced white matter microstructural integrity in SPD patients and that DTI microstructural parameters in posterior tracts correlate strongly with sensory dysfunction and abnormal MSI, while left frontal tract integrity correlates specifically with a measure of inattention. These findings suggest abnormal white matter as a biological basis for SPD and help to distinguish SPD from overlapping clinical conditions such as autism and ADHD. Using brain-behavior correlations, we hope to move towards a more individualized understanding and treatment of children with sensory processing differences.

Maturation of the Brain Stem and Cerebellar White Matter Tracts from the Neonatal Period to Adolescence: A Diffusion Tensor Imaging Study

Poretti, A.·Meoded, A.·Yoshida, S.·Huisman, T. A. G.
The Johns Hopkins Medical School
Baltimore, MD.

Purpose

Diffusion tensor imaging (DTI) allows to study the normal development of white matter tracts. Several studies focused on the supratentorial white matter tracts. Almost no data are available about the temporal changes of DTI scalars for the infratentorial white matter tracts during the progressing myelination. We evaluated the quantitative changes of fractional anisotropy (FA) and mean (MD), axial (AD), and radial (RD) diffusivity within the brain stem and cerebellar white matter tracts from the neonatal period to adolescence.

Materials & Methods

We selected 96 subjects (47 females, 49 males, age three days to 17.9 years) with normal brain anatomy and absence of neurologic disorders. Single-shot spin-echo, echo-planar axial DTI sequences were acquired on a 1.5T MR scanner. Balanced pairs of diffusion gradients were applied along 20 orthogonal directions. Atlas-based analysis with parcellation of the brain in 130 regions was performed using MRI Studio software. The following infratentorial white matter tracts were evaluated: corticospinal tract, medial lemniscus, and superior, middle, and inferior cerebellar peduncles.

Results

For all white matter tracts, an increase of FA and decrease of MD, RD, and less pronounced, AD values were seen over time. For all white matter tracts, changes in DTI parameters were higher for the youngest subjects (younger than 12 months of age). Additionally, changes in DTI parameters, particularly MD, RD and AD, differed depending on the studied white matter tracts and were higher for the corticospinal tracts and middle cerebellar peduncles compared to medial lemnisci and superior and inferior cerebellar peduncles.

Conclusion

The changes in DTI parameters correlate well with the normal myelination and developmental processes. The most pronounced changes were seen in white matter tracts that myelinate later. We report on normative values for pediatric DTI parameters of the infratentorial white matter tracts using atlas-based analysis.

Longitudinal Comparison of Diffusion Tensor Imaging Values in Neonates with Hypoxic Ischemic Encephalopathy Undergoing Hypothermia Treatment

Lee, P. N.·Tymofiyeva, O.·Glass, H.·Bonifacio, S.·Ferriero, D.·Barkovich, J.·Xu, D.
University of California San Francisco
San Francisco, CA.

Purpose

Diffusion tensor imaging (DTI) is a valuable tool for studying brain development in infants with hypoxic ischemic encephalopathy (HIE). Low apparent diffusion coefficient (ADC) values due to injury can be detected before abnormalities are seen on conventional anatomical MR imaging, these have prognostic value in neonates with HIE. We studied neonates with HIE by evaluating the DTI values at approximately four days of life and at six months and correlated these to outcome status at six months. A longitudinal comparison then was performed to determine changes over time across outcome groups.

Materials & Methods

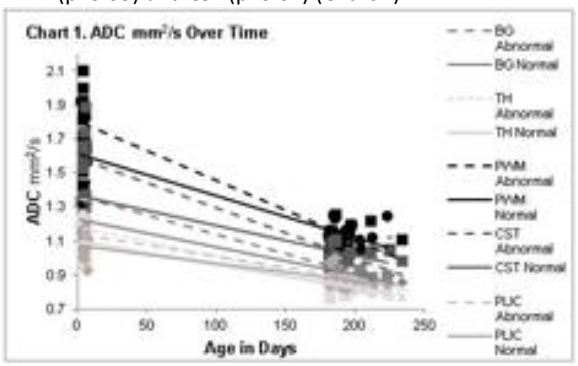
Comprehensive MRI exams with DTI were performed at approximately four days and again at six months of life for 36 newborns with HIE who underwent hypothermia

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

treatment. All subjects were examined by a pediatric neurologist at six months of age and were neurologically evaluated using a Neuromotor Scoring (NMS) system validated at our institution. Thirty-six percent of the patients had abnormal neurologic outcome with a NMS≥2. A basal ganglia (BG), thalamus (TH), parietal white matter (PWM), cortical spinal tract (CST), and posterior limb of the internal capsule (PLIC) regions of interest (ROI) were drawn bilaterally on the ADC maps. Left and right ROIs were statistically similar and were combined for analysis. The difference between the late and early scans was used for the longitudinal comparison. Linear regression with age correction was performed.

Results

Infants with abnormal outcome had higher ADC values in all regions, with significant differences in the PWM (p=0.03) and CST (p=0.01) regions at the neonatal scan. At six months, significantly higher ADC in the abnormal group was found only in the PLIC (p=0.05). The abnormal cohort showed a significantly steeper change over time in the PWM (p=0.03) and CST (p=0.01) (Chart 1).



Conclusion

Apparent diffusion coefficient values in subjects with abnormal outcome approached those of subjects with normal outcome by the six month time point, though elevated ADC was still seen in the PLIC on the six month scan. It is interesting to note that prior studies with uncooled neonates showed reduced diffusion in regions of injury, while the current study showed increased diffusion; the reason for the increased diffusivity after cooling is being investigated. Given that hypothermia provides incomplete neuroprotection, this technique may be useful in choosing which subjects will benefit from additional neuroprotective therapies.

Diffusion Tensor Imaging in Hypoxic Ischemic Encephalopathy Treated with Therapeutic Hypotheremia

Niogi, S. N.·Rosenbaum, D.·Perlman, J.·Heier, L.·Kovanlikaya, A.
Weill Cornell Medical College
New York, NY.

Purpose

Perinatal hypoxic-ischemic encephalopathy causes significant disability in newborns and accounts for about 25% of children with cerebral palsy. As of yet, there is no reliable biomarker to predict which of these infants will have poor outcome. Diffusion tensor imaging (DTI) is more sensitive to white matter changes than conventional clinical MRI and can possibly detect subtle variations in white matter in these infants which may better assess severity. In the current study, we use DTI to evaluate white matter integrity in a priori selected regions to predict clinical outcome.

Materials & Methods

Subjects included 19 infants that were imaged between six and nine days of age. Subjects underwent therapeutic hypothermia and were examined at 18-24 months to assess clinical outcome. Subjects were divided into good outcome (neurologic normal) or poor outcome (death or motor/cognitive abnormalities). Subjects were scored with the Bayley Scale of Infant Development. Diffusion tensor imaging was performed using a 1.5T MRI GE scanner using a 33 gradient direction sequence. A semi-automated region of interest (ROI) approach, the Reproducible Objective Quantification Scheme (ROQS) was adopted to test 12 specific tracts selected in an a priori fashion based on prior studies. As a post-hoc test, 3D tractograms of these pathways also were created using home-grown software adopting a streamlined technique. Fractional anisotropy (FA) for the ROIs and tractograms of these tracts were correlated with the Bayley score and FA from subjects in good and poor outcome groups was compared using 2-tailed nonparametric statistics.

Results

White matter integrity measured by FA of the anterior limb of the internal capsule (ALIC) bilaterally, the left posterior limb of the internal capsule (PLIC), and forceps major (FM) bilaterally predict clinical outcome from both 2D ROI and tractogram measurements (statistics from 2D ROIs: right ALIC $p = 0.012$, left ALIC $p = 0.014$, left PLIC $p = 0.035$, right FM $p = 0.009$, left FM $p = 0.002$). The FM tract bilaterally also correlated with Bayley Scores of development (right FM $r = 0.62$, $p = 0.016$, left FM $r = 0.70$, $p = 0.009$). Conventional clinical MRI and other clinical measures cannot adequately predict outcome in infants that have suffered hypoxic-ischemic encephalopathy. However, DTI is sensitive to subtle microstructural changes overlooked by conventional imaging. As shown in this study, variations in white matter integrity in specific pathways (the ALIC, PLIC, and FM) can predict clinical

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

outcome after treatment with therapeutic hypothermia.
Conclusion
Diffusion tensor imaging detects subtle variations in white matter and can be performed to possibly predict outcome following therapeutic hypothermia in infants suffering from hypoxic-ischemic encephalopathy, one of the predominate causes of cerebral palsy.

KEYWORDS: Pediatric brain, DTI

MR Imaging and Spectroscopy Findings in Perinatal Hypoxic-Ischemic Injury following Whole Body Cooling

Kitamura, G.·Bartnik-Olson, B. L.·Merritt, T. A.·Peverini, R.·Kido, D.·Wycliffe, N.·Oyoyo, U.
Loma Linda University
Loma Linda, CA.

Purpose
To determine whether neonates with perinatal hypoxic-ischemic injury (HII) who underwent whole body cooling demonstrated fewer imaging abnormalities when compared to noncooled neonates.
Materials & Methods
A retrospective chart review revealed 39 neonates with HII who underwent 72 hours of whole body cooling (HII/HT+) and 20 neonates with HII who did not undergo whole body cooling (HII/HT-). Inclusion and exclusion criteria for whole body cooling were similar to those in the literature. Magnetic resonance spectroscopy (MRS), magnetic resonance imaging (MRI), and susceptibility-weighted imaging (SWI) data were acquired between 0-20 days after birth. In addition, nine healthy neonates imaged within the same time frame were included in the study as a control group. MR spectroscopy values analyzed included N-acetyl aspartate (NAA), creatine (Cr), choline (Cho), myo-inositol (Ins), and lactate (lac) in the mid-occipital gray matter (OGM), basal ganglia (BG) and thalami (TH). MR imaigng findings were assessed using the previously validated Barkovich scores evaluating T1, T2, proton density (PD), and diffusion-weighted imaging (DWI) findings in the basal ganglia (BG), watershed region (W) and combined basal ganglia-watershed region (BGW). Susceptibility-weighted imaging findings were analyzed using a 7-point ordinal scale evaluating the prominence of cerebral deep medullary veins (POV). Neurologic outcome at discharge was evaluated with the previously validated outcome-predicting encephalopathy score. A *p*-value less than 0.05 was considered to be statistically significant.
Results
There was no significant difference in demographic or discharge variables among the control, HII/HT+, and HII/HT- groups, except with the Miller encephalopathy score, which was higher in the HII/HT- group. Compared to the HII/HT- group, fewer neonates in the HII/HT+ group had lactate detected in the OGM and TH. N-acetyl aspartate level in the OGM and NAA/Cho ratio in the TH also were higher in the HII/HT+ group when compared to the HII/HT- group. The HII/HT+ group demonstrated lower MRI Barkovich scores compared to the HII/HT- group. The HII/HT- group demonstrated a higher number of patients with abnormal POV values when compared to the HII/HT+ group.
Conclusion
Neonates with hypoxic-ischemic injury undergoing whole body cooling demonstrated differences in MRI, MRS, and SWI imaging findings when compared to neonates with hypoxic-ischemic injury who did not undergo whole body cooling. These findings may represent the alteration in cerebral metabolism that occurs with whole body cooling, and may be utilized in the workup of neonates with hypoxic-ischemic injury.

P-103

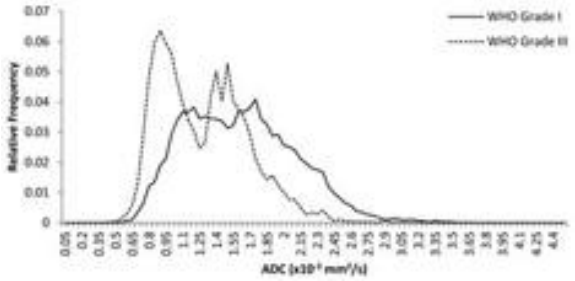
Institutional Choroid Plexus Tumor Apparent Diffusion Coefficient Histogram Analysis and Comparison of Tumor Grade Values

Kamer, A. P.·Cardinal, J.·Ho, C.
Indiana University School of Medicine
Indianapolis, IN.

Purpose
To evaluate the utility of diffusion-weighted imaging (DWI) in discriminating choroid plexus tumor grade using quantitative analysis with whole-tumor ADC histograms.
Materials & Methods
This study was granted exemption status by our Institutional Review Board. MR imaging data were collected retrospectively for choroid plexus tumors at our institution that had a tissue diagnosis and preoperative DWI. Whole-tumor regions of interest were hand drawn on the apparent diffusion coefficient (ADC) maps for each tumor, and the ADC value was automatically extracted for each included voxel using an in-house MATLAB script. Individual whole-tumor ADC and WHO grade group summation ADC histograms were generated. Statistical metrics were calculated for each tumor including average, standard deviation, skew, kurtosis, and several percentiles. The metrics for the two tumor grades were compared with each other using unpaired, two-tailed Student *t*-test to evaluate for statistically significant differences or trends.
Results
Seventeen WHO grade I (mean age, 5.4 years; range, 2 months - 42 years) and three WHO grade III (mean age, 6 months; range, 3 months -1 year) choroid plexus tumors were included. Mean ADC values for WHO III tumors (1.26 x 10-3 mm2/s) tended to be lower than those for WHO I tumors (1.59 x 10-3 mm2/s), but without statistical significance (P = 0.21). Percentile measures and peak location also tended lower in WHO III tumors, but without statistical significance. Skew and kurtosis, measures of asymmetry and peakedness respectively, revealed no clear

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

trends (P=0.32 and P=0.57, respectively). Nearly all individual tumor histograms demonstrated a single dominant peak, while the normalized WHO grade group summation histograms demonstrated bimodal distributions. Individual tumors tended to have relatively low variance in ADC values compared to higher variance in ADC values grouped by tumor grade.



Conclusion
Assessment is limited given only three WHO grade III choroid plexus tumors; however, our results suggest that DWI and quantitative analysis of whole tumor ADC distribution is not clinically useful for discriminating choroid plexus tumor grade. Different ADC peaks for two populations of WHO grade I tumors suggests the presence of two separate subsets of papillomas. Additional research may further clarify these findings.

P-104

Primary Brain Tumors in the First Year of Life: What Is Rare and What Is Common?

Decarie, J.·Bernier Turmel, F.
Hopital Ste-Justine
Montreal, QC, CANADA.

Purpose
The purpose of this study is to present a retrospective analysis of primary brain tumor types in children less than one year old treated at a large tertiary care pediatric center. Our goal was to determine the number, the histologic distribution, and the location of primary brain tumors in the first year of life and compare our results with data previously reported.
Materials & Methods
A retrospective study was made of primary brain tumor patients presenting in the first year of life at Saint-Justine Hospital between 2002 and 2012. Nineteen cases were identified through the Pediatric Oncology Service registry. The following data were compiled for each case: Age of patient at time of diagnosis, dimensions of tumor, location and histologic type.
Results
In our study, supratentorial tumors were the most frequent location (74%) and astrocytomas, predominantly benign, represented 52% of all tumors, data in agreement with the literature. Teratoma, suprasellar/thalamic astrocytoma, atypical teratoid rhabdoid tumor, ependymoma, choroid plexus tumor and craniopharyngioma are the most commonly reported types in the literature. However, 42% of our cases are not considered as typical tumor for this age group and 26% of our cases fall in the group of rare tumors. Our series suggests that the spectrum of histologic types is wider than previously reported and that some histologic types considered before as rarities should be included in the differential diagnosis of primary brain tumor for this age group.
Table 1: Histologic types distribution

Histological types	No. of patients (%)
Pilocytic Astrocytoma (WHO grade I)	7 (37)
Pilomyxoid Astrocytoma (WHO grade II)	1 (5)
Anaplastic Astrocytoma (WHO grade III)	2 (11)
Choroid Plexus Papilloma (WHO grade I)	1 (5)
Atypical Choroid Plexus Papilloma (WHO grade II)	1 (5)
Choroid Plexus Carcinoma (WHO grade III)	1 (5)
Medulloblastoma	1 (5)
Pineoblastoma	1 (5)
Pituitary Blastoma	1 (5)
Atypical Teratoid /Rhabdoid Tumor	1 (5)
Desmoplastic Neuroepithelial Tumors	2 (11)

Conclusion
Our study suggests that the spectrum of histologic types of primary brain tumors encountered during the first year of life should be expanded to include types previously reported as rare or very rare as 42% of our cases belonged to that group.

KEYWORDS: Pediatric brain tumors, Epidemiology

Radiation Dose Reduction and Protocol Optimization for Pediatric Head CT in Evaluation of Ventricular Size

Gabriel, S.·Eckel, L. J.·Wood, C. P.·Thielen, K. R.·DeLone, D. R.·Krecke, K. N.·Luetmer, P. H.·Bruesewitz, M. R.·McCollough, C. H.·Kofler, J. M.·Yu, L.
Mayo Clinic
Rochester, MN.

Purpose
Radiation dose is an important concern for public health, especially for pediatric patients. In recent times, rapid MR has been promoted as an alternative to CT for evaluation of ventricular size in patients with treated, long-term hydrocephalus. However, MR is not routinely available during off hours or at all institutions. Given this and the sizable number of pediatric patients with treated, long-term hydrocephalus who often need status evaluation of their ventricular size, additional radiation reduction in CT was investigated as a viable imaging alternative. The objective of this work was to determine the minimum radiation dose that still adequately evaluates ventricular size in this pediatric population.
Materials & Methods
Raw data from clinical pediatric head CTs performed on a 128-slice CT scanner (Definition Flash, Siemens Healthcare) was collected and transferred to an external workstation. The exams included five heads on pediatric patients, ranging in age from six months to 14 years. Using a validated noise insertion tool developed at our institute, three different noise levels were inserted into each raw dataset, resulting in unique datasets simulating 50%, 25%, and 10% of the original dose level. Each dataset was reconstructed using both original filtered-back projection (FBP) and sinogram affirmative iterative reconstruction (SAFIRE) methods. For each case, each dose level and reconstruction method, both soft tissue and bone kernel images were produced. Eighty different images were generated (five patients x four dose levels x two reconstruction methods x two kernels) and then independently evaluated by experienced neuroradiologists who were blinded to the dose and reconstruction method. The radiologists indicated which of the 80 images provided acceptable image quality, thereby allowing the lowest acceptable dose to be determined.
Results
Both the soft-tissue and bone reconstruction images reduced to 10% of the original dose were deemed clinically acceptable to the group of neuroradiologists. No perceptible difference between reconstruction methods was detected. Based on the results from reconstruction, the average CTDIvol for patients was reduced by 90% from 26.6 mGy ± 12.1 mGy to approximately 2.7 mGy. Using the conversion factor for a five-year-old patient, the dose was effectively reduced to 0.16 mSv, roughly equivalent to that of a chest radiograph.
Conclusion
A novel noise insertion tool to simulate reduced-dose exams from existing patient exams was validated. Dose reductions of 90% were realized while maintaining acceptable image quality to answer the specific clinical question of ventricular size. At such reduced CT doses, long patient term patient radiation exposure is significantly reduced, workflow efficiency is improved (including avoiding patient transport to a facility with a MRI scanner) and exposures to MRI safety risks reduced utilizing CT as a reasonable alternative to emergent MRI.

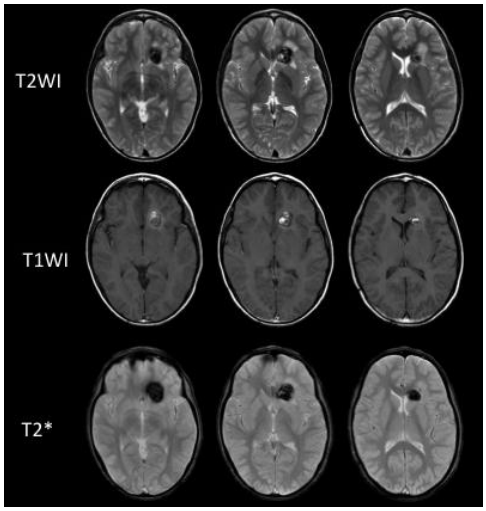
P-105a

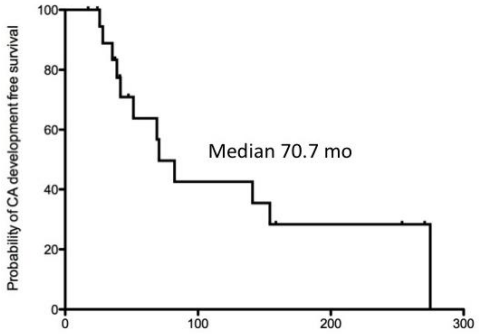
Usefulness of T2 Star/Susceptibility-Weighted Imaging for Detection of Cavernous Angioma after Cranial Irradiation for Treatment of Embryonal Tumors

Yamasaki, F.·Watanabe, Y.·Takayasu, T.·Nosaka, R.·Akiyama, Y.·Saito, T.·Sugiyama, K.·Kurisu, K.
Hiroshima University Hospital
Hiroshima, JAPAN.

Purpose
The incidence of cavernous angiomas after cranial irradiation is unclear as is the role of T2*- or susceptibility-weighted imaging in their diagnosis. We investigated the incidence of cavernous angioma after cranial irradiation using T2*- or susceptibility-weighted imaging.
Materials & Methods
Between 1990 and 2011, 34 patients with embryonal tumors (22 medulloblastomas, six primitive neuroectodermal tumors, six pineoblastomas) were treated at our institution; 31 received cranio-spinal irradiation. All underwent surveillance MRI studies at least once a year. The diagnosis of cavernous angioma was based solely on MRI results. None of the patients underwent surgery for cavernous angioma and none of the lesions were confirmed histologically.
Results
At the time of the last surveillance studied 20 patients were alive and disease-free. Among them, 12 had developed cavernous angiomas after cranial irradiation, in nine patients there were multiple cavernous angiomas. Three patients developed symptomatic lesions (headache/diplopia/abducens palsy); their cavernous angiomas were classified as Zabramski type 3 or 4.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.





Conclusion
We attribute the higher incidence of cavernous angioma after cranial irradiation in our studies - rather than earlier studies - to our use of T2*- or susceptibility-weighted imaging. Based on our experience we recommend that T2*- or susceptibility-weighted imaging be included in follow-up studies of patients treated by cranial irradiation.

Survey into the Prevalence of Radiation-Induced Lens Injury (Cataracts) in Interventional Neuroradiologists

Djoukhadar, I. A.[1]·Jeeva, I.[2]·Chang, B.[2]·Patankar, T.[1]·Goddard, A.[1]
[1]Leeds Radiology Academy, Leeds, UNITED KINGDOM,
[2]Leeds Teaching Hospitals, Leeds, UNITED KINGDOM.

Purpose
Observational study to assess the prevalence of radiation-induced cataract in neurointerventionists.
Materials & Methods
All delegates present at a national neuroradiology conference (Leeds, UK) were invited for a vision check and dilated pupil examination to assess for the presence of cataracts. Examination was performed by a slit lamp and the Lens Opacity Classification System (LOCS-III) was used to assess disease severity. All neurointerventionists with at least two years or a minimum of 50 procedures experience were invited to take part. Exclusion criteria included ocular comorbidities and allergy to Tropicamide or Phenylephrine.
Results
A total of 15 participants took part with age range of 32 - 59 years and male to female ratio of 13:2. Nine doctors were compliant with eye protective goggles. Seven of 15 participants had a cataract that was considered more than the age-matched control. However, only two had visually significant cataracts. This group did not need surgery as vision improved with the use of glasses. The prevalence of cataracts in the goggles-compliant group was three of nine and for the noncompliant group four of six.
Conclusion
This small-scale study shed some light on the prevalence of “radio-cataract” among interventional

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

neuroradiologists. Further study with a larger number of participants would be useful in determining the true disease incidence.

Lessons Learned from Restructuring MR Imaging Patient Scheduling: A Quality Improvement Project

Ametlli, V.·Wessman, B.·Stickney, K.·Hartzog, J.·Davis, M.·Scarpace, L.·Bower, L.·Faulkner, M.·Remer, S.·Jain, R.
Henry Ford Health System
Detroit, MI.

Purpose
Scheduling a magnetic resonance imaging (MRI) study requires a lot of preparation before an appointment slot can be given to a patient. The one-year transformation from paper to electronic ordering of imaging exams and development of an electronic protocol application at our institution greatly improved processing quality but did not remove barriers to provide patients with same-day MRI appointments. Difficulties in scheduling same-day appointments resulted from varying time for appointments depending on the study and availability of MRI equipment, prior insurance authorization check, proper patient screening and backlog of appointments to schedule. A Lean process improvement team was assembled with the purpose of improving the turnaround time for scheduling an MRI from an average of 4.8 days to same day through process redesign, maximizing resources and elimination of waste. The purpose of this presentation will be to describe this process in detail, discuss the hurdles we faced and our results.
Materials & Methods
A team comprised of key process stakeholders from customer service representatives, technologists, specialty clinic nurses, neuroradiologists, project facilitators, computer analysts and MRI leadership used the PDCA cycle and Lean tools as the foundation to guide the continuous improvement journey. The team mapped current state process and with patient involvement identified opportunities for improvements. Development of key process measures along with baseline data collection guided direction and prioritization of efforts. Five subgroups were formed and met on a weekly basis during the six-month project period to implement action plans. Leveraging home-grown electronic systems assisted in timely data analysis and implementation of electronic changes. On-going communication to team members and staff assisted in ownership and engagement in solving problems.
Results
Through redesigning scheduling process, revision of MRI sequencing protocols, standardizing scheduling blocks, automating exam timing, decreasing radiologist time to protocol order (days to hours), development of service standards and optimization of pre-authorization process, the improvement team was able to streamline steps to schedule the appointment and reduce turnaround time for scheduling from 4.8 days to same day. The improvements benefited patients and especially clinics such as Neurosurgery, who were dependent on the patient completing their study in a timely manner to assist with treatment plan. Process efficiency gains resulted in reducing financial cost by 3 FTEs, a cost saving of $120,000/year.
Conclusion
The commitment from leadership in supporting establishment of a multidisciplinary team combined with using a structured problem-solving methodology allowed the team to produce results that exceeded the area benchmark of 72 hours for an MRI appointment. The combined innovative changes provided financial savings but most importantly the project team spread a culture of problem-solving and improvement in the department. To ensure changes are sustained over time, key process owners are tracking and taking action as needed. The efficiency gains in standardization of exam timings are being spread across the Health System as it prepares to roll-out a new Electronic Medical Record system. Readers will gain an understanding of how to apply Lean methodology to develop a patient-centered scheduling model.

Quality Efforts Centered on Mitigating Clinical Impact of an Unusual MR Imaging Artifact

Watson, R. E.[1]·Welker, K. M.[1]·Wood, C. P.[1]·Miller, G. M.[1]·Prescott, S. L.[1]·Kollasch, P. D.[2]
[1]Mayo Clinic, Rochester, MN, [2]Siemens Healthcare, Malvern, PA.

Purpose
To describe a clinical scenario in which a coordinated effort including neuroradiologists, quality office personnel at the departmental and institutional level, medical physicists, and vendor applications specialists quickly mitigated the potential clinical impact of a previously unrecognized artifact in MRI. These efforts identified that the artifact was produced when a new abdomen-optimized flow compensation technique on T1 3D turbo spin-echo with variable flip angle (T1 SPACE) images was used in the brain. The artifact manifested by subtle pseudoenhancing "lesions" in patients with concomitant T2 signal hyperintensities in the brain. A culture of safety focus facilitated rapid and thorough addressing of the issue.
Materials & Methods
A new flow-compensation method utilized in abdominal imaging to reduce signal from blood flow in the liver on T2 STIR imaging was applied to gadolinium-enhanced T1

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

SPACE images of the brain to decrease dural venous sinus pulsation artifact. Preliminary studies in volunteers demonstrated decreased pulsation artifact and no apparent image degradation. This technique then was implemented clinically for contrast-enhanced brain studies. After approximately six weeks of use the possibility of subtle pseudo-enhancement was recognized. This prompted a medical physics, vendor applications specialist, and quality office investigation of the 108 contrast-enhanced clinical brain exams during this period that included the new post-gadolinium T1 SPACE flow compensation technique. 26 neuroradiologists reviewed these cases to assess for potential spurious conclusions that may have been a result of this artifact. When needed, the electronic medical record was reviewed and referring clinicians contacted.

Results

The inclusion of the new flow compensation technique on contrast-enhanced T1 SPACE images produced variable subtle pseudo ring enhancement about the periphery of T2 hyperintense foci. This included around areas of presumed leukoaraiosis, demyelinating plaques and other lesions. In one case, there were ring-enhancing pseudolesions surrounding sites of T2 hyperintensity in both cerebral hemispheres which resulted in a differential diagnosis of parasitic, infectious, embolic, or neoplastic etiologies. This prompted additional clinical investigation and body CT, MR, and US studies, spine MRI, as well as a lumbar puncture. In another case, despite the presence of pseudo enhancement about some lesions, there were other lesions with presumed true enhancement and clinical management was not altered. The first patient described above returned for additional imaging including T1 SPACE sequences performed with and without the new flow compensation, and both before and after intravenous gadolinium contrast administration. This demonstrated that the T1 hyperintensity about T2 hyperintense foci was present and unchanged both before and after IV gadolinium administration, confirming that this was due to artifact. Quality office personnel at both the departmental and institutional level closely monitored the analysis through its completion.

Conclusion

This clinical scenario illustrates the value to patient safety of coordinated collaborative work between radiologists, medical physicists, quality experts, along with vendor support specialists to quickly problem-solve a previously unknown imaging artifact and the extent of its clinical impact.

Efficacy of CT-Guided Blood Patch for Treatment for Intracranial Hypotension: Our Experience

Chai, B. B.·Huang, R. Y.
Brigham and Women's Hospital
Boston, MA.

Purpose

Blood patch is the mainstay treatment for spontaneous intracranial hypotension (SIH). Although targeted blood patch has been shown to have greater efficacy compared to blinded blood patch, a significant number of patients presenting with SIH have an unknown leak site despite imaging workup. We retrospectively evaluated 24 patients with SIH in our institution from 2009-2012 who have had a negative total spine CT myelography and evaluated the success rate of symptom improvement and symptom recurrence following lumbar blood patch alone, upper thoracic spine blood patch alone, or successive lumbar blood patch and upper thoracic blood patch.

Can Radiofrequency Kyphoplasty Improve the Pulmonary Function?

Pflugmacher, R.·Bornemann, R.·Jansen, T. R.·Kabir, K.·Wirtz, D. C.
Universitätsklinikum Bonn
Bonn, GERMANY.

Purpose

Vertebral compression fractures not only reduce the activities of daily living (ADL) because of pain, they also cause respiratory dysfunction. This study investigates the

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

impact of radiofrequency kyphoplasty treatment not only on the reduction of back pain and the restoration of vertebral body height, but also on pulmonary function.
Materials & Methods
Twelve patients (six male; mean age 67.6 ± 10.4 years) with vertebral compression fractures at the lumbar spine L1 (n = 7) or L2 (n = 5) were treated by radiofrequency kyphoplasty. The Oswestry Disability Index (ODI) and back pain, assessed by the visual analog scale (VAS; 10 cm), were evaluated by each patient one day before the procedure and 30 days after the procedure. The vertebral body height at anterior, medial and posterior aspect was measured one day before the procedure, one day after the procedure and 30 days after the procedure. For evaluation of pulmonary function a spirometer was used to determine the one-second forced expiratory volume (FEV1) and the peak expiratory flow (PEF), one day before the procedure, one day after the procedure and 30 days after the procedure.
Results
The treatment of vertebral compression fractures via radiofrequency kyphoplasty led to significant reduction of back pain (VAS) 30 days after treatment compared with one day before, 77.6 ± 14,4 (mean ± standard deviation) and 17.2 ± 27,1, respectively. The ODI decreased significantly from 74.7 ± 13.6% one day before the procedure to 21.0 ± 16.2% 30 days after the procedure. There was considerable restoration of vertebral body height one day after the procedure with mean values of 2.8 mm, 3.7 mm and 0.3 mm at the anterior, medial and posterior aspect, respectively. Vertebral body height decreased minimally 30 days after the procedure; however there still was notable restoration in comparison to one day before the procedure by 1.0 mm at the anterior, 1.8 mm at the medial and 0.0 mm at the posterior aspect. There was minimal improvement of pulmonary function as early as one day after the procedure and significant values were obtained 30 days after the procedure ($p<0.01$). The improvement of FEV1 one day after the procedure compared with one day before was 0.1 l/s and 30 days after the procedure compared with one day before 0.4 l/s. The PEF improved one day after the procedure compared with one day before by 50.6 l/min and 30 days after the procedure compared with one day before by 75.2 l/min.
Conclusion
The treatment of vertebral compression fractures at the lumbar spine by radiofrequency kyphoplasty, not only restored the vertebral body height, reduced pain or improved ODI, but also improved pulmonary function significantly.

Is There an Association between Abnormal MR Imaging Signal Intensity of the Nerves around the Elbow Joint and Professional Baseball Pitching?

Thawait, S. K.[1]·Farahani, S. J.[2]·Thawait, G. K.[2]·Demehri, S.[2]·Chhabra, A.[2]
[1]Bridgeport Hospital, Bridgeport, CT, [2]Johns Hopkins Hospital, Baltimore, MD.

Purpose
Repetitive micro-trauma due to frequent throwing results in increased susceptibility to peripheral nerve injury in professional baseball pitchers. The purpose of this study is to evaluate the association between abnormal T2 hyperintensity of the peripheral nerves around the elbow joint and professional baseball pitching.
Materials & Methods
Axial fat-saturated T2W images were reviewed retrospectively for presence of abnormal T2 hyperintensity of the radial, median and ulnar nerve around the elbow joint, which was defined as similar or higher signal intensity than the adjacent vessels. Following the blinded review of MR images, the frequency of abnormal T2 hyperintensity of the nerve was calculated in professional pitchers and nonpitchers. A univariate model was designed to examine the probability of significant difference in these two groups. To adjust for the effect of confounding factors and not normality of data distribution, a multivariate regression model was used.
Results
Out of 96 MRI examinations reviewed, 74 were found to be satisfactory. Thirty-four subjects (11 F, 23 M; age 49±15 years) were nonpitchers, while 40 subjects (1 F, 39 M; age 24±5.8 years) were professional pitchers. Radial nerve hyperintensity was seen in 2/34 (6%) of the nonpitchers and 9/40 (23%) of the pitchers (p value 0.06). Median nerve hyperintensity was seen in 3/34 (8%) of the nonpitchers and 10/40 (25%) of the pitchers (p value 0.05). Ulnar nerve hyperintensity was seen in 13/34 (38%) of the nonpitchers and 19/40 (47.5%) of the pitchers (p value 0.42). T2 hyperintensity of median and radial nerves were close to being significant. After adjusting the model for age and sex as a confounding factor and not normality of median and redial nerve data distribution, no significant difference between the professional pitchers and nonpitchers in terms of frequency of hyper-intensity of the selected nerves was detected.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

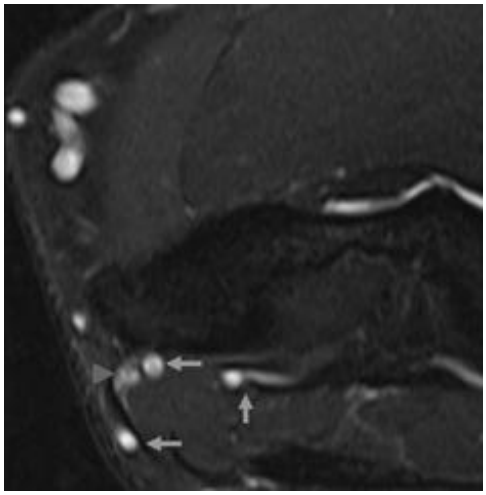

Figure: Axial fat-saturated PD image shows increased signal intensity of ulnar nerve (arrowhead), almost equal to signal intensity of adjacent vessels (arrows) in a professional baseball pitcher.

Conclusion

The results indicate that abnormal T2 hyperintensity of peripheral nerves around the elbow joint is seen commonly in professional pitchers, although the difference was not significant statistically. A larger sample with normal asymptomatic population which will serve as control cases might be helpful in examining the possible association. This finding of hyperintensity of peripheral nerves should be included in the report as early recognition and appropriate therapy may prevent further neurologic damage and permanent irreversible neuropathy.

KEYWORDS: Nerve imaging, Neurography, peripheral nerve MR imaging

P-112

Structure-Function Relationship in Healthy and Myelopathic Spinal Cord: A Combined Diffusion Tensor Imaging and Functional MR Imaging Study

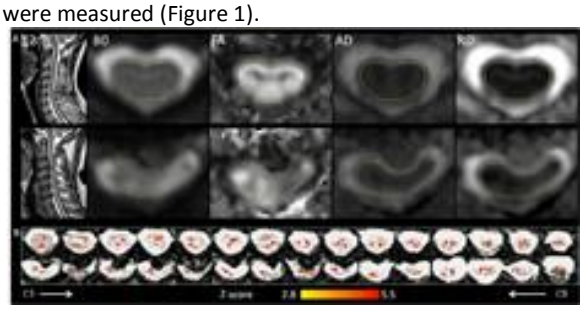
Cui, J.·Li, X.·Luk, D.·Hu, Y.
The University of Hong Kong
Hong Kong, HONG KONG.

Purpose

Currently magnetic resonance imaging (MRI) plays an important role in the diagnosis of cervical spinal cord disorders [e.g., cervical spondylotic myelopathy (CSM)]. The conventional T1- and T2-weighted MRI has provided great benefits in terms of rapid, noninvasive and accurate imaging of cord morphology. However, it is reported that the morphologic and signal change do not necessarily correlate with functional behavior and clinical symptoms. Recently, diffusion tensor imaging (DTI) and blood oxygen level-dependent (BOLD) MR imaging has been developed rapidly to investigate the microstructure and functional behavior of the spinal cord. In this study, we aim to combine the anatomical, functional and diffusion tensor MRI to explore the relationship between function and structure in healthy and myelopathic cervical spinal cord.

Materials & Methods

A total of twenty subjects were recruited with written informed consent, including 14 healthy subjects (age=56±13 years) and six CSM patients (age=67±14 years). Anatomical T2-weighted, diffusion tensor and functional MRI were scanned covering the whole cervical spinal cord from C1 to C7 on a 3T MR system. Cross-sectional area, compression ratio, fractional anisotropy, axial diffusivity, radial diffusivity and BOLD signal change were measured (Figure 1).



Results

The result showed that BOLD signal change in response to somatosensory stimuli was significantly higher in myelopathic cord (7.86±0.95%) compared to healthy cord (5.52±0.21%) ($p<0.01$). Significant differences were detected between healthy and myelopathic cord for: cross-sectional area (Healthy: 81.78±15.59; CSM: 61.35±14.71, $p<0.05$), compression ratio (Healthy: 58.33±13.03%; CSM: 51.51±10.13%, $p<0.05$), fractional anisotropy (Healthy: 0.65±0.07; CSM: 0.53±0.10, $p<0.01$) and radial anisotropy (Healthy: $0.63\pm0.12\times10^{-3}$ mm^2/s; CSM: $1.05\pm0.47\times10^{-3}$ mm^2/s, $p<0.01$). There was no significant difference of axial diffusivity between healthy subjects and CSM patients (Healthy: $1.71\pm0.14\times10^{-3}$ mm^2/s; CSM: $1.73\pm0.13\times10^{-3}$ mm^2/s) ($p>0.05$). BOLD signal change indicated a much stronger correlation with FA value (Healthy: $r=0.4887$, $p=0.0764$; CSM: $r=-0.8938$, $p=0.0163$) and RD value (Healthy: $r=-0.5348$; $p=0.0488$; CSM: $r=0.8239$; $p=0.0438$) compared to that with compression ratio or cross-sectional area.

Conclusion

Our results indicate that diffusion tensor measurement provides a more accurate estimation of spinal cord functional behavior than morphometry. Moreover, greater microstructural damage was significantly and linearly correlated with enhanced activation in myelopathic cord, which implies the functional reorganization in CSM. This study demonstrates a quantitative relationship between the extent of structural integrity and functional response in healthy and myelopathic cord, which might provide a promising method to gain additional insight into the role of structural damage and functional reorganization in the spinal cord diseases.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Retrospective Validation of a Rapid Lumbar Spine MR Protocol for Assessment of Patients with Acute Atraumatic Cord Compression Presenting to the Emergency Room

Boe, D. L.[1]·Farquhar, T.[2]·Greenwood, M.[2]·Herbst, T.[2]·Zimmerman, D.[2]·Bansal, A.[2]
[1]Hartford Hospital, Hartford, CT, [2]Hartford Hospital, Rocky Hill, CT.

Purpose
Nontraumatic acute spinal cord injury (NT/SCI) and cauda equina syndrome are medical emergencies that if not identified and treated early can lead to permanent neurologic deficits. MR imaging is strongly recommended for diagnosis and prognosis of acute spinal cord injury and can be used to direct clinical decision-making; sagittal T2 sequences are of particular diagnostic utility. There are many etiologies of acute NT/SCI, including spinal stenosis, bulky disk herniation, compression from a mass, infection, and vascular compromise. Delay in treatment can result in permanent neurologic deficits. The ideal protocol should be both sufficiently informative, yet not time-consuming to perform or interpret. Utilization of MRI continues to increase, particularly in the ER setting. The purpose of this study is to optimize and retrospectively validate an MRI protocol for acute NT/SCI for the emergency department at Hartford Hospital, a busy tertiary care hospital that triages over 100,000 patients/year in the ED. A rapid protocol could reduce the time to patient treatment, facilitate the clinician's ability to obtain an MRI for more patients in general, as well as for patients who are medically unstable, and decrease overall cost by reducing scan time.
Materials & Methods
Sagittal T1 (noncontrast) and T2 sequences from 30 consecutive MRI examinations of the lumbar spine ordered from the emergency department for NT/SCI were pulled from the Hartford Hospital PACS, without regard to whether the studies initially had been performed with or without contrast. Four radiologists (two experienced neuroradiologists, DLZ and MMG, and two experienced radiologists with subspecialties other than neuroradiology, TF and TH) were blinded to the clinical and demographic information of the subjects as well as the previous interpretation. Their interpretations based on the sagittal T1 and T2 sequences only were compared with the original interpretations (DLB and AB).
Results
The overall accuracy of all readers was extremely high, ranging from 83-90%. There was substantial agreement between readers as well (Cohen's kappa of 0.71 between neuroradiologists and 0.77 between non-neuroradiologists). When noncontrast studies were evaluated separately, performance was significantly better, with accuracy rates ranging from 91-100%. In particular, both neuroradiologists were 100% accurate with all noncontrast exams. Accuracy on studies initially performed with contrast ranged from 74-84%.
Conclusion
A lumbar MRI protocol limited to sagittal T1- and T2-weighted sequences for assessment of acute atraumatic NT/SCI presenting to the ER is a robust technique with high interobserver agreement across radiologists in multiple subspecialties. This protocol can accurately diagnose specific etiologies of acute NT/SCI, especially for exams that are requested without gadolinium contrast. Implementation of this protocol in the ED setting has the potential to reduce the time to treatment for patients, limit patient morbidity and mortality, facilitate a clinician's ability to obtain an MRI for more patients, and decrease overall cost by reducing scan time.

Utility of CT-Guided Bone Biopsy for Vertebral Osteomyelitis

Bauml, J. A.·Bosman, S. A.·Hansra, N.·Saran, N.
University of Illinois at Chicago Medical Center
Chicago, IL.

Purpose
CT-guided bone biopsy has been advocated as a useful tool to aid in the diagnosis and treatment of suspected vertebral osteomyelitis. No large review study providing convincing evidence supporting this practice is available. This single institution retrospective study is aimed at providing concrete data to help guide the discussion and debate over the usefulness of image-guided bone biopsy for vertebral osteomyelitis.
Materials & Methods
Data pertaining to vertebral body bone biopsies performed from January 2003 to March 2011 at the University of Illinois Hospital Chicago was compiled. Antibiotic regimens/treatment plans (prebiopsy) for the patients undergoing biopsy were recorded. Alterations in treatment plan based on the results of these biopsies were analyzed. The study design was that of a retrospective chart review.
Results
Of the 109 total vertebral body biopsies performed during the study period, 72 were performed for clinically or radiologically suspected cases of vertebral osteomyelitis. Fifty of these patients with clinically diagnosed osteomyelitis had negative culture results. Of the patients with negative culture results, the biopsy changed management in one case, but that change was based on unexpected pathology rather than culture results. In seven patients the biopsies never yielded a diagnostic culture. The total number of positive culture results from these 72 biopsies was 15. Two of those patients were lost to

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

followup. Out of the 13 remaining patients, the treatment plan for nine was changed based on the results. Four out of nine were not on prebiopsy antibiotics and were started on tailored therapy. Five out of nine patients' preexisting antibiotic regimens were tailored. Of the 65 specimens that were successfully cultured by microbiology, 15 cultures were positive. This corresponds to a culture positivity rate of 23%. In summary, nine patients who underwent biopsy had their management changed on the basis of the microbiology report. However, the other 57/72 (87.5%) patients who underwent biopsy for culture did not have their treatment changed as a result.

Vertebral biopsies performed by radiology for suspected osteomyelitis 1/2003 to 3/2011

	N	% of total	N Culture result changed treatment	% Treatment changed
Osteo suspected clinically and biopsy ordered	72		9/72	12.5%
Biopsy sample successfully obtained	70	97.2%	9/70	12.9%
Positive Culture	15	23.1%	9/15	60.0%
Negative Culture	50	76.9%	0/50	0.0%
Error in transfer*	4			
Improper preparation**	1			

*Pathology was performed on specimen but the specimen was not received by microbiology
** Specimen sent in formalin and unable to be used for culture

Conclusion
Because (1) image-guided bone biopsies fail to provide an etiologic microorganism in most cases of clinically suspected osteomyelitis-diskitis and (2) in the setting of positive culture results broad-spectrum antibiotics often are continued unchanged, and (3) osteomyelitis is a clinical diagnosis and therefore a negative culture does not allow one to cease antibiotics in suspected cases: bone biopsy may not be a useful tool to guide treatment except in cases in which there is high clinical suspicion of an atypical organism such as tuberculosis.

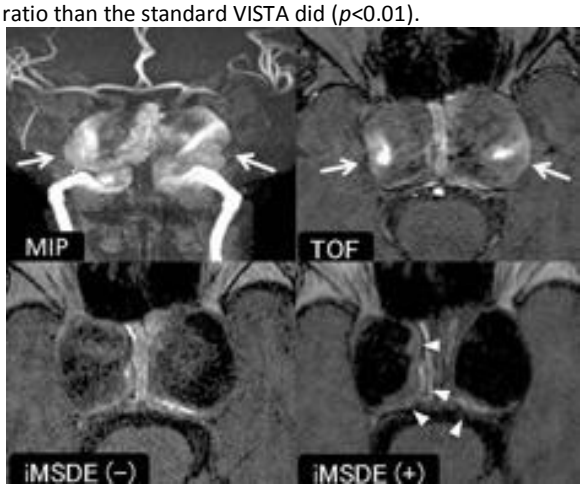
Clinical Assessment of Improved Motion Sensitized Driven Equilibrium Prepared T1-Weighted Black-Blood Imaging for Intracranial Aneurysms

Maeda, M.[1]·Inoue, K.[1]·Umino, M.[1]·Yamahata, T.[1]·Suwa, A.[2]·Sakuma, H.[1]
[1]Mie University School of Medicine, Tsu, JAPAN, [2]Philips Electronics Japan, Tokyo, JAPAN.

Purpose
Thrombotic aneurysm can cause complicating events at the time of the intravascular or surgical treatment. Therefore, the precise detection of thrombus is of value for treatment strategies. Black-blood imaging (BBI) has been proposed for the assessment of vessel wall abnormalities. However, current BBI techniques provide insufficient images because of flow-related artifacts, particularly in intracranial vessels. This study is intended to evaluate the flow suppression capability of improved motion sensitized driven equilibrium (iMSDE) prepared sequence compared with standard BBI in patients with intracranial aneurysms.
Materials & Methods
Thirty-two patients with intracranial aneurysms were studied using 3T (Achieva; Philips Co.). The aneurysm diameter was 13.2 $\pm$ 7.1 mm. Black-blood imaging techniques included the standard 3D T1-weighted fast SE (VISTA) and the iMSDE-prepared VISTA. Visual assessment for flow suppression was performed using a four-point score. Quantitative assessment was achieved using the contrast ratio between the luminal signal within the aneurysm and adjacent brain parenchyma.
Results
Visual assessment showed that the iMSDE-prepared VISTA

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

was significantly higher in scores than the standard VISTA (p<0.01). The signals inside aneurysms, particularly with diameter greater than 9 mm, were suppressed more strongly using iMSDE, indicating that the vessel wall boundary was more clearly visualized and that the thrombus was more definitely depicted if present (Figure). Quantitative assessment revealed that the iMSDE-prepared VISTA provided a significantly better contrast ratio than the standard VISTA did (p<0.01).



Conclusion

The iMSDE-prepared BBI was able to suppress the signal of intracranial aneurysms more strongly than the standard BBI can. Improved motion sensitized driven equilibrium-prepared BBI appeared to be more suitable for detection of thrombus within intracranial aneurysms.

Volume of Interest C-Arm CT Imaging during Endovascular Treatment of Aneurysms: A Comparison of Various Truncation Correction Algorithms

Chintalapani, G.[1]·Chinnadurai, P.[1]·Shaltoni, H.[2]·Morsi, H.[2]·Mawad, M. E.[3]
[1]Siemens Medical Solutions USA Inc., Hoffman Estates, IL, [2]St. Luke's Episcopal Health System, Houston, TX, [3]Baylor College of Medicine, Houston, TX.

Purpose

Volume of interest (VOI) imaging allows additional and repeated C-arm CT acquisitions during the endovascular treatment without significant increase in radiation exposure (70-80% reduction in dose), thus providing real-time 3D information of the device deployment status and vessel wall apposition during the procedure. However, current VOI reconstruction techniques suffer from severe truncation artifacts because of the smaller field of view. Hence, we propose to evaluate three different truncation correction algorithms developed for VOI imaging.

Materials & Methods

Volume of interest images were obtained in 10 patients undergoing endovascular treatment of intracranial aneurysms. 20s-DR DynaCT (Axiom Artis zee, Siemens AG, Forchheim, Germany) images were acquired by iso-centering around the implanted device with the x-ray source collimated on the VOI (approximately 12% size of the full volume). The VOI images were reconstructed using three different offline prototype reconstruction algorithms (Water Cylinder, ATRACT 1D, and ATRACT 2D) that correct for truncation artifacts. The resulting VOI reconstructions were compared to secondary reconstructions from full volume C-arm CT images using image similarity metric, in particular structural similarity index metric (scale of 0-1, with 0 being completely dissimilar images and 1 being exactly similar images).

Results

Qualitative analysis shows that the VOI images are comparable to the secondary reconstructions from a full volume image (Figure 1). Quantitative comparison of image similarity metric between the prototype VOI reconstructions and the ground truth reconstruction (from full head acquisition) show a similarity index of 0.7, 0.72, and 0.74 respectively. Moreover, the similarity metric for high contrast objects such as flow diverters, stents etc. is very close to 1 (Figure 1).

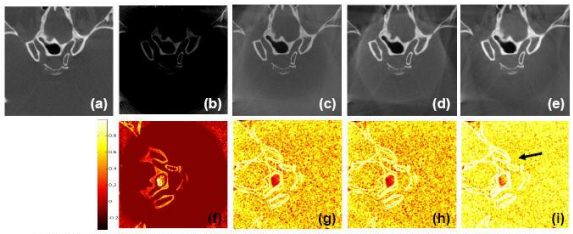

Fig 1. (a) secondary reconstruction from full head scan, (b) standard reconstruction of a VOI acquisition, (c)-(e) prototype reconstructions with truncation correction algorithms for VOI acquisition, (f) structural similarity index between (b) and (a), (g) structural similarity index between (c) and (a), (h) structural similarity index between (d) and (a), and (i) structural similarity index between (e) and (a). Note the high contrast objects such as flow diverter and bones have a similarity index close to 1.

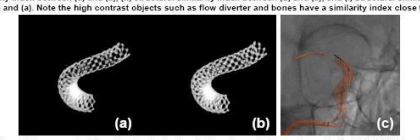

Fig 2. (a) VRT rendering of the segmented flow diverter device from full head acquisition as shown in Fig 1(a), (b) VRT rendering of the segmented flow diverter device from VOI reconstruction with truncation correction as shown in Fig 1(c), (c) An example of segmented flow diverter device overlaid on fluoroscopic images for further image guidance.

Conclusion

All three proposed truncation correction algorithms for VOI imaging perform almost similarly resulting in high quality 3D images of the object of interest (especially high contrast structures like stents, pipeline embolization devices, etc). Volume of interest imaging during endovascular treatment of aneurysms can provide immediate feedback on the device deployment status and the vessel wall apposition. In addition, 3D image of the deployed device can be segmented and overlaid on 2D fluoroscopy for image guidance through the rest of the procedure.

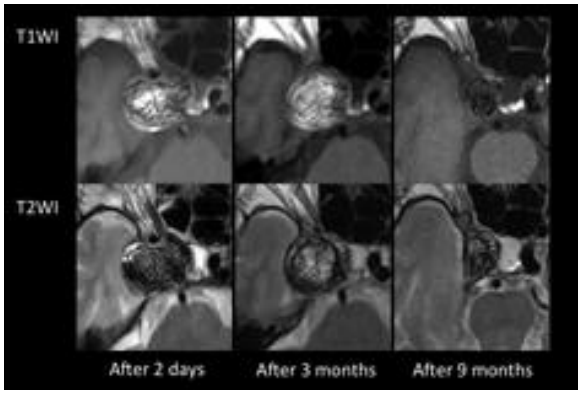
Serial MR Findings of Giant and Large Internal Carotid Aneurysms after Endovascular Parent Artery Occlusion

Morikawa, M.·Enokizono, M.·Koike, H.·Uetani, M.·Hayashi, K.·Horie, N.·Fukuda, S.·Nagata, I.
Nagasaki University
Nagasaki, JAPAN.

Purpose
The aim of this retrospective study was to evaluate the serial MR findings of giant and large internal carotid aneurysms after endovascular parent artery occlusion.
Materials & Methods
Between 2003 and 2011, we treated 12 patients of giant/large internal carotid aneurysm, including 11 unruptured and one ruptured at our institution. Maximum diameter of the aneurysm ranged from 18 to 65 mm (average of 31 mm). Nine of the 12 patients presented with diplopia, one with reduced visual acuity, one with massive nasal bleeding, and remaining one with no symptom. Proximal parent artery occlusion with rough packing of the aneurysm was performed in eight unruptured aneurysms, trapping with rough packing in three unruptured aneurysms and trapping without packing in one ruptured aneurysm. Total 82 MRI/MRA were performed in the follow-up period ranging from14 to 71 months. We evaluated the change of size and signal intensity (SI) of the aneurysms after endovascular treatment.
Results
Reduction of the aneurysm size was observed in 10 of 12 treated aneurysms during follow-up period. The volume of these 10 aneurysms fell to 20-75% of its initial value 8 to 61 months after treatment. In six of the 10 aneurysms, MR was performed within four days after endovascular treatment, and these aneurysms demonstrated high SI on T1-weighted image (T1WI), and low or mixed high/low SI on T2-weighted image (T2WI). As reduction in size of the 10 of 12 aneurysms, high SI areas within the aneurysms on T1WI became iso to low SI, and low or mixed SI on T2WI gave high SI. In remaining two of 12 treated aneurysms, the size of the aneurysms was unchanged or increased up to 15%, and high SI foci on T1WI and low SI foci on T2WI appeared in different region of the aneurysms during follow-up period. Digital subtraction angiography confirmed the recanalization of these two aneurysms.



Conclusion
Signal intensity of aneurysms after parent artery occlusion had demonstrated low SI on T1WI and high SI on T2WI with shrinkage of the aneurysms. Appearance of high SI foci on T1WI and low SI foci on T2WI in the aneurysm after treatment indicates recanalization within the aneurysm.

Evaluating Parenchymal Abnormalities Associated with Developmental Venous Anomalies Identified by Susceptibility-Weighted Imaging at 3T

Umino, M.[1]·Maeda, M.[1]·Matsuura, K.[2]·Sakuma, H.[1]
[1]Mie University School of Medicine, Tsu, JAPAN, [2]Suzuka Kaisei Hospital, Suzuka, JAPAN.

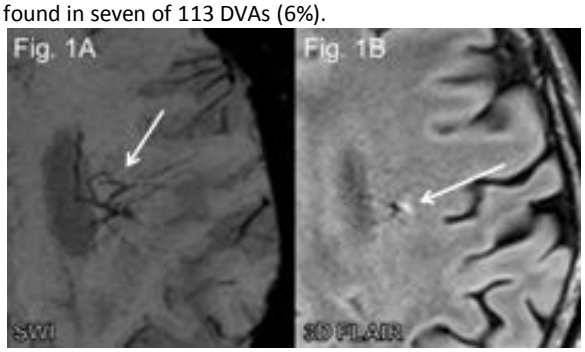
Purpose
Since the introduction of susceptibility weighted imaging (SWI), developmental venous anomaly (DVA) has been more incidentally encountered in clinical practice. Susceptibility-weighted imaging enables better visualization of DVAs without requiring any contrast medium. The parenchyma drained by DVA is generally normal, but a few reports have described associated parenchymal abnormalities near DVA, including high signal lesions of the white matter and hemorrhage and/or cavernous hemangioma. More recently, Santucci et al. reported the prevalence of high signal lesions associated with DVAs as 7.8%. However, no report has described the prevalence of brain parenchymal abnormalities associated with DVAs that were identified using SWI. This study is intended to evaluate the prevalence of brain parenchymal abnormalities associated with DVAs identified using SWI at 3T.
Materials & Methods
During January 2008 - November 2012, all brain MR imaging cases studied with SWI at 3T MR machines were reviewed at our hospital and one branch hospital, among which 124 DVAs were identified by SWI. Of those DVAs, 11 DVAs were excluded because abnormal parenchymal findings associated with DVAs could not be determined as a result of underlying white matter changes such as

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

ischemic leukoaraiosis. Eventually, 113 DVAs in 112 patients (46 male, 66 female, mean age 55.4 years) were enrolled in this study. We investigated the presence or absence of parenchymal high signal intensities on 2D or 3D FLAIR, as well as hemorrhage and/or cavernous hemangioma on SWI associated with DVAs.

Results

Associated high signal lesions were found in 35 of 113 DVAs (30.9%). A mean maximum diameter of high signal lesions was 12.7 ± 8.1 mm (range 2-33 mm), and high signal lesions typically surrounded DVAs. In four of the 35 DVAs, 3D FLAIR showed a small high signal spot along with DVAs (Figure 1). Concomitant hemorrhage and/or cavernous hemangioma possibly related to DVAs were found in 21 out of 113 DVAs (18.5%). High signal lesions and hemorrhage and/or cavernous hemangioma were found in seven of 113 DVAs (6%).



Conclusion

The prevalence of brain parenchymal high signal lesions associated with DVAs might be higher than that reported previously (30.9% vs. 7.8%). Our results suggest that a small high signal spot along with DVAs might be an early finding of associated parenchymal high signal lesions.

Can 3D Time-of-Flight MR Angiography at 3T Replace Digital Subtraction Angiography in the Characterization of Intracranial Dural Arteriovenous Fistulas?

Hirai, T.·Azuma, M.·Kitajima, M.·Shigematsu, Y.·Kai, Y.·Yamashita, Y.
Kumamoto University
Kumamoto, JAPAN.

Purpose

Since the quality and spatial resolution of images acquired by unenhanced three-dimensional (3D) time-of-flight (TOF) MR angiography (MRA) are improved on 3T MR units, it may replace digital subtraction angiography (DSA) for certain diagnostic purposes in patients with intracranial dural arteriovenous fistulas (DAVF). The purpose of this study was to test the hypothesis that unenhanced 3D TOF MRA at 3T yields the similar characterization of intracranial DAVFs as DSA.

Materials & Methods

Twenty-six consecutive patients with intracranial DAVF (13 women, 13 men; aged 35 - 76 years, mean 60 years) underwent 3D TOF MRA at 3.0T and DSA. The parameters for 3D TOF MRA were TR/TE 20 ms/3.5 ms, flip angle 20°, field of view 20 x 20 cm, matrix 512 x 512, slab 5 chunks, voxel size 0.39 x 0.39 x 1.0 mm (reconstructed voxel size 0.25 x 0.25 x 0.5 mm), parallel imaging factor 2, acquisition time 4 min 48 sec. When a lesion was located at the top of the head, another MRA slab was rostrally added using the same parameters. The main arterial feeders, fistula site, and venous drainage pattern were inspected by two independent observers on 3D TOF MRI and by two other independent readers on DSA. According to the Borden's classification, DAVF drainage was recorded as type 1, drainage directly into the dural venous sinus; type 2, drainage into the dural venous sinus with cortical venous reflux; and type 3, drainage directly into subarachnoid veins. Interobserver and intermodality agreements were assessed by *k* statistics.

Results

At DSA, 13 fistulas were located at the cavernous sinus, six at the transverse sigmoid sinus, two at the hypoglossal canal, two at the superior sagittal sinus, and three at other sites. Interobserver agreement was very good for the main arterial feeders (k = 0.83), excellent for the fistula site (k = 0.94), and very good for the venous drainage pattern (k = 0.88). Intermodality agreement was very good for the main arterial feeders (k = 0.89), the fistula site (k = 0.90), and the venous drainage (k = 0.81).

Conclusion

As unenhanced 3D TOF MRA at 3T is a reliable tool for the evaluation of intracranial DAVF, it may replace DSA to some extent in the characterization of intracranial DAVFs.

Target Delineation for Radiosurgery of a Small Brain Arteriovenous Malformation Using High-Resolution Contrast-Enhanced Cone-Beam CT

van der Bom, I. M. J.·Gounis, M. J.·Ding, L.·Kuhn, A.·Goff, D.·Puri, A. S.·Wakhloo, A. K.
University of Massachusetts
Worcester, MA.

Purpose

Radiosurgery has shown to be a very effective treatment option for brain arteriovenous malformations (bAVMs). Currently, the gold standard technique for diagnostic and follow-up imaging is digital subtraction angiography (DSA). Although this modality provides excellent spatial and temporal resolution, radiosurgery planning using DSA can be tedious as it only provides 2D spatial information. Here we propose the use of high-resolution contrast-enhanced

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

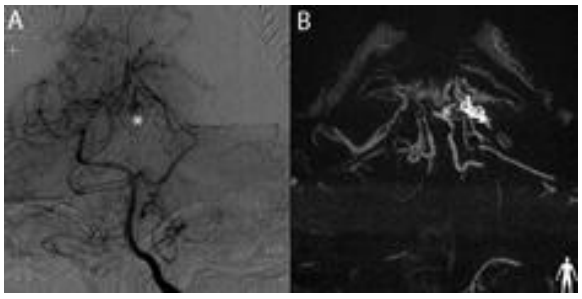
cone-beam computed tomography (VasoCT) data, acquired with an angiographic c-arm system, as a 3D planning dataset.

Materials & Methods

Magnetic resonance imaging (MRI), simulation CT, and VasoCT were acquired of a patient with a micro-bAVM of the superior colliculus prior to radiosurgery treatment. Unlike DSA or VasoCT, MRI or CTA did not show the bAVM. VasoCT imaging was performed with a flat-panel, bi-plane c-arm system (Philips Healthcare) using a reduced detector format of 22 × 22 cm^2 in a non-binned mode. During the acquisition, 20% iodinated contrast agent was administered (2 ml/s for a total of 64 ml) into the right vertebral artery using a 5 Fr catheter. Volumetric data were generated (matrix: 512 × 512 × 512; voxel: 0.13 × 0.13 × 0.13 mm^3) using a reconstruction algorithm which allows for visualization of detailed structures at the cost of lower signal-to-noise. All image data were imported into a treatment planning system (Eclipse, Varian Medical Systems) and co-registered. Target delineation was performed on VasoCT slices by an experienced neuroradiologist and dose planning was performed accordingly. The patient received four radiosurgery treatments of 5 Gy on a Trilogy accelerator.

Results

Ten months after final radiosurgery session, the patient underwent a follow-up imaging by catheter angiography showing a complete obliteration of the bAVM and no untoward effects of the radiation treatment. In Figure A the anterior-posterior DSA is given that demonstrates a 3 mm left superior colliculus/pituitary bAVM (asterix). A maximum intensity projection of 5 mm coronal slab of VasoCT data is given in Figure B, in which the bAVM nidus (asterix), the arterial supply through cerebellar arteries and venous drainage trough left superior collicular vein into the vein of Galen are visible.



Conclusion

High-resolution contrast-enhanced cone-beam CT has shown to be a feasible method for direct target delineation for radiosurgery in 3D. The nidus of the micro-bAVM was readily visible on VasoCT data and acquisition and including the complementary image data was adopted easily into the standard workflow of radiosurgery.

Cognitive Impairment in Nondemented ALS and PLS Patients: A Combined Neuropsychologic, DTI and Morphologic Study

Meoded, A.·Kwan, J. Y.·Peters, T. L.·Huey, E. D.·Danielian, L. E.·Morrissette, A.·Wu, T.·Grafman, J.·Floeter, M. K.
National Institute of Neurological Disorders and Stroke, National Institutes of Health
Bethesda, MD.

Purpose

Many patients with amyotrophic lateral sclerosis (ALS) develop impaired executive function, which requires integrity of fronto-temporal networks, and behavioral impairment, suggestive of dysfunction in limbic networks. Primary lateral sclerosis(PLS) is a rare form of motor neuron disorder in which cognitive function has been less well studied than in ALS. The aims of our study were: 1) to explore correlations between DTI metrics of association and commissural tracts and deficits in performance of particular cognitive tests, 2) to explore correlations between gray matter volumetric changes and deficits in performance of cognitive tests, and 3) to compare DTI metrics in patients with and without cognitive and behavioral changes.

Materials & Methods

Seventeen patients who fulfilled Pringle's criteria for PLS, thirteen patients with probable or definite ALS by revised El Escorial criteria, and seventeen age-matched healthy controls participated in the study. In patients, neuropsychologic testing consisted of the Delis-Kaplan Executive Function Scale (D-KEFS) and Mattis Dementia Rating Scale (DRS). On all subjects, structural MRI and DTI was performed. DTI postprocessing included atlas-based analysis (ABA) using MRI Studio software. With this method we measured the fractional anisotropy (FA), mean (MD), axial (AD), and radial (RD) of selected white matter tracts. Voxel-based morphometry was performed using SPM8 in order to assess differences of gray matter volume. Correlations between diffusion properties of selected association and commissural white matter tracts and cognitive performance were analyzed for the patient group as a whole. This model assessed three components derived from the D-KEFS: Fluency, Sorting, and Trails; the DRS total T-score; and DRS memory T-score. In addition, we compared DTI metrics in patients with and without cognitive (ALSci) and behavioral (ALSbi) changes.

Results

Significant associations were found between the total DRS score and FA in the right cingulum and increased RD of the left inferior fronto-occipital-fasciculus. The DRS memory subscore was associated with increased AD of the left and the right IFO and with FA in the right posterior thalamic radiation. Among the executive function tests, the only significant correlation was between verbal fluency and AD of the superior longitudinal fasciculus. Volumetric analysis demonstrated reduced gray matter volume in ALS patients

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

in the right pre and postcentral gyrus and in PLS patients in the left supplementary motor area, paracentral lobule, mid cingulum, superior frontal, and precentral gyrus, and in the right pre and postcentral and middle frontal gyrus. However, there was no correlation between volume loss in these areas and neuropsychologic measures. Finally, we found higher FA and lower RD in the right cingulum in patients with ALSci ($p = 0.0106$). In patients with ALSbi, higher FA was seen in the left cingulum ($p = 0.0049$) and lower RD in the right cingulum ($p = 0.0087$).
Conclusion
Changes in diffusion metrics in selected white matter tracts were associated with a decline in global and selected cognitive measures. The involvement of long association fibers together with commissural tracts supports the theory of dysfunction of multiple networks and regions, not only the well-known fronto-temporal but also occipital and parietal areas.

Susceptibility-Weighted Imaging Phase Values of the Whole Gray and White Matter in Patients with Multiple Sclerosis and Neuromyelitis Optica: A Comparative Study with Controls

Itagiba, V. G. A.[1]·Lopes-Rueda, F. C.[1]·Doring, T.[1]·Domingues, R. C.[1]·Bahia, P. V.[2]·Leon, S. V. A.[2]·Gasparetto, E. L.[1]
[1]DASA- Diagnósticos da América, Rio de Janeiro, BRAZIL, [2]Universidade Federal do Rio de Janeiro, Rio de Janeiro, BRAZIL.

Purpose
To analyze the phase change on susceptibility-weighted imaging (SWI)-filtered phase images in the whole gray and white matter (WM) of multiple sclerosis (MS) and neuromyelitis optica (NMO) patients compared to healthy controls (HC). First, we sought to create a reliable, reproducible and highly automated framework for structure-specific analysis of SWI-filtered phase images. Second we aim to apply this technique to groups of MS and NMO patients and HC in order to analyze the phase change in the whole gray matter (GM) and WM, of these groups.
Materials & Methods
Sixteen relapsing-remitting multiple sclerosis (RRMS) patients, nine NMO patients and 24 HC were imaged on a 1.5T scanner. A postprocessing method was used to create single automated generated masks for the whole GM and WM. Radian values (RV) were determined for the whole GM and WM of MS and NMO patients and HC.
Results
A significant difference ($p = 0.0182$) was detected between the RV of the GM of MS patients and HC. No significant difference was detected when comparing the RV of the WM of MS patients and HC ($p = 0.1416$). There also was no significant difference of the RV of the GM ($p = 0.6966$) and WM ($p = 0.9282$) when comparing NMO patients and HC, neither when comparing NMO and MS patients GM ($p = 0.5352$) and WM ($p = 0.5222$).
Conclusion
We were able to assess the whole GM and WM of MS and NMO patients and we found a significant difference between the RV of the GM in MS patients compared to HC. The possibility of having a single mask including the whole GM and WM would improve the iron overload detection. Future studies should focus on testing this method with a larger cohort, in order to improve the technique and to demonstrate its utility. Clinical relevance statement: This postprocessing method is fast, easy to execute and provides a wider range of information of the whole brain's phase changes what would improve the iron overload detection.

Cortical Thickness Changes over the Entire Lifespan

Santos, A. C.·Cunha, H. H.·Escorsi-Rosset, S.·Salmon, C. E. G.
University of Sao Paulo
Ribeirao Preto - SP, BRAZIL.

Purpose
After birth a maturation process including myelination and cortical thickness reduction occur at a fast rate, followed by a slow but steady cortical thinning over the entire lifespan. At the end, in the aging brain, a new acceleration occurs in specific regions. While these age-related changes in gray matter volume have been studied extensively, less has been done using newer morphologic indexes, such as cortical thickness and surface area and the studies usually focus on subjects older than 19 years. However, cumulative evidence also indicates that this atrophy is not uniform, and significant heterogeneity of age effects is observed across brain regions. The interpretation of this heterogeneity is complicated by the many variables involved during the entire aging process, mainly the known cellular maturation changes that occur between childhood and adolescence (i.e., myelination, synaptic pruning) which is the cause of most previous research in this area. On the other hand, it is very important to understand how the brain changes as a function of aging. The aim of the present study was to address this problem by testing the consistency of age effects in a unique and general way, from childhood to old age, discussing the interactions between the ages and separating the aging in two moments: maturation and aging itself.
Materials & Methods
Brain imaging data were collected from 143 control subjects (6 - 86 years old); 72 men. All imaging data were

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

acquired using a 8-channel head coil on a 3T Philips Achieva X-Series, including a T1-w MPRAGE sequence with whole brain coverage and isotropic voxel of 1 mm^3. All images were processed using FreeSurfer v5.1.0 (http://surfer.nmr.mgh.harvard.edu/) which performs a reconstruction of the cortical surface and uses some automated approaches to parcel and measure thickness, gray matter volume and surface area. The cortical surface was divided into 74 different areas in each hemisphere. Mean thickness then was extracted for each brain region from each individual subject's brain image in its native space. We separated the whole process in two stages: maturation and aging, and computed the best threshold for each region, allowing identifying when those processes begin, their velocities and the relation to aging. Age effects on all data were analyzed using a Java Software constructed specifically to support and optimize the resolution of this study. The software uses the Apache Commons Mathematics Library to handle the regressions and all statistical operations required and MySQL as the main database. Beside age comparison in specific regions, we analyze sex differences in the age effects.
Results
Our data are in according with previous studies pointing to a different rate of growing and decrease of each single brain region.
Conclusion
Because brain regions have different compositions of neurons in the laminar cortex it is possible to think about different neuronal rate of maturation and senescence which might have importance in the understanding of neuronal death in different degenerative diseases.

Association between Cognitive Decline and Structural Connections in Patients with Mild Cognitive Impairment

Prescott, J. W.·Guidon, A.·Liu, C.·Doraiswamy, P. M.·Petrella, J. R.·The Alzheimer's Disease Neuroimaging Initiative
Duke University Hospital
Durham, NC.

Purpose
The hypothesis of the current study is that the number of structural connections in cortical regions involved in Alzheimer disease (AD) decreases with decreasing cognitive performance, as measured by the mini mental status exam (MMSE) clinical score, in patients with mild cognitive impairment (MCI).
Materials & Methods
1. Subjects included in the analysis were those newly enrolled in the ADNI2 study who were assigned to either the early MCI or late MCI cohorts, and who had baseline DTI scans available. 2. The ADNI2 protocol describes the acquisition protocols in depth. 3. Each subject's baseline SPGR anatomical images were segmented using FreeSurfer "freesurferaparc" parcellation, producing 83 regions of interest. 4. The b0 DTI scans were registered to the anatomical scans using FSL. Fiber tractography then was used to derive structural connectome maps using the Connectome Mapper Toolkit (CMTK). 5. The anatomical parcellation labels then were registered to the connectome map. The strength, or number of structural fibers connected to an anatomical region, and the degree, or number of other cortical regions connected to an anatomical region, then were analyzed in seven anatomical regions, or "nodes", in each brain hemisphere: precuneus, posterior cingulate, parahippocampus, entorhinal, inferior temporal, superior parietal, and superior frontal. These regions were selected because of their known association with AD pathology. A linear regression analysis was performed on the node strength and degree in each anatomical region and MMSE score at baseline.
Results
There were 45 ADNI2 subjects (29 males, 15 females) in the MCI cohorts that had baseline DTI and anatomical SPGR scans available at the time of the analysis. The average age was 71.5 ± 12.3. The average MMSE score was 27.6 ± 1.8. There were significant associations (p less than 0.05) between node strength and MMSE in left posterior cingulate and borderline significant associations (p less than 0.10) in right posterior cingulate, left entorhinal, and left superior parietal regions. There were no significant associations between node degree and MMSE. All regions which demonstrated significant or borderline significant associations had a positive association, such that the node strength decreased as the MMSE score decreased (signifying cognitive decline). In the left and right posterior cingulate regions, patients with high MMSE scores (greater than 28) did have more high strength connectivities (greater than 200) than those with lower MMSE scores (less than 25) - 11:2 in the left and 12:1 in the right. However, the best fit linear regressions did not characterize the data well across the entire MMSE spectrum (R-squared less than 0.10 for all regions).
Conclusion
Although there may be decreases in the structural connections of the posterior cingulate regions that track over the entire range of decreasing cognitive performance in patients with MCI, the largest differences are between patients with high MMSE scores (greater than 28) and those with low MMSE scores (less than 25). This relationship can be analyzed further as more MCI patient data are added to the ADNI2 database, particularly longitudinal scans.

Multimodal MR Imaging of Single versus Multiple Domain Amnestic Mild Cognitive Impairment

Abdel Razek, A.·Tantawy, A.·Elkhateb, M.·Elsayed, M.
Mansoura University Hospital
Mansoura, EGYPT.

Purpose
To differentiate between single domain and multiple domain subtypes of amnestic mild cognitive impairment (MCI) with MR imaging.
Materials & Methods
Prospective study was conducted upon 50 patients with multiple domain (n = 38) and single domain (n = 12) amnestic MCI (65 ± 5 years, 38 male, 12 female). They underwent T1-weighted 3D magnetization prepared rapid gradient echo (MP-RAGE) sequence, diffusion MR weighted imaging with B value of 0, 500 and 1000 s/mm2 and multivoxel MR spectroscopy of the brain with TE of 270 ms. The apparent diffusion coefficient (ADC) value, the volume and metabolic ratios of different regions of the brain of multiple domain and single domain MCI were calculated. Statistical analysis was done.
Results
There was significant difference in the ADC value of the parietal region (P = 0.01), Ch/Cr ratio of the parietal regions (P = 0.02), and volume of the hippocampus (P = 0.03) and amygdale (P = 0.05) between single domain and multiple domain amnestic. The best combination for differentiation was ADC value and Ch/Cr ratio of parietal region. The cutoff value of ADC, Cr/cr ratio and volume were 0.78, 284, 0.83 with areas under the curve of 0.883, 0.893, and 0.821 respectively.
Conclusion
We concluded that the combination of ADC value and Ch/Cr ratio of the parietal region is a promising noninvasive imaging parameter used for differentiating multiple domains from single domain amnestic MCI.

Decoding the Superior Parietal Lobule Connections of the Superior Longitudinal Fasciculus in the Human Brain: A High-Resolution Diffusion Tensor Tractography Study on 3T

Kamali, A.[1,2]·Flanders, A. E.[3]·Hasan, K.[4]
[1]University of Medicine and Dentistry of New Jersey, Camden, NJ, [2]Cooper University Hospital, Camden, NJ, [3]Thomas Jefferson University Hospital, Philadelphia, PA, [4]University of Texas Medical School Houston, Houston, TX.

Purpose
Inferior parietal lobule connections of the language pathways such as the middle longitudinal fasciculus (MdLF) and temporoparietal connections of the superior longitudinal fasciculus (TP SLF) have been described in the literature. Extensive crossing fibers at the corona radiata at the level of the lateral ventricles as well as lack of adequate imaging sensitivity and spatial resolution, so far, impeded depiction of superior parietal lobule connections of the temporoparietal language pathways in prior diffusion tensor imaging studies. This work aimed to explore the acuity and feasibility of visualization of white matter substructure of the human language pathways connecting the temporal lobe with the superior parietal lobule using a high-resolution diffusion tensor imaging technique and deterministic tractography approach.
Materials & Methods
Subjects**:** Five healthy men (age range 24-37 years) were studied and written informed consent was obtained from all subjects. Conventional and DT-MRI Acquisition: Data were acquired using a Philips 3.0T Intera system using a SENSE receive head coil. Diffusion-weighted image (DWI) data were acquired axially using a single-shot multi-slice 2D spin-echo diffusion with the balanced *Icosa21* tensor encoding scheme. The b-factor = 500 sec mm-2, TR/TE = 14460/60 msec, FOV = 256 mm x 256 mm and slice thickness/gap/#slices = 1 mm/0 mm/120. The EPI phase encoding used a SENSE k-space undersampling factor of two, with an effective k-space matrix of 112 x 112 and an image matrix after zero-filling of 256 x 256.
Results
Numerous anatomical details in the brain white matter connectivity have been undetectable or poorly detectable due to discrepancy of scale between the microstructural anatomy and inadequate image resolution and sensitivity used in diffusion tensor imaging. Using higher resolution combined with higher magnetic field reduced the partial volume effects and incoherency within the voxel. This allowed us to trace the superior parietal lobule connections of the temporoparietal pathways and reveal more anatomical details of the temporoparietal language pathways. In our experience these superior parietal lobule connections of the temporoparietal fibers are not traceable using slice thickness ~ 3 mm. This is attributable to mixing of fibers in different orientations within the voxel leading to lack of adequate anisotropy in larger voxel volume which was solved by using thinner slices and smaller voxel volume.
Conclusion
In this report we demonstrate for the first time the feasibility of in vivo tracing the superior parietal lobule connections of the temporoparietal pathways using high-resolution diffusion tensor tractography.

KEYWORDS: 3 T, Diffusion tensor image, high-resolution, superior longitudinal fasciculus

eP-13

Functional and Structural Connectivity Helps to Detect and Understand Alzheimer Disease

Santos, A. C.·Rondinoni, C.·Rolo, J.·Escorsi-Rosset, S.·Salmon, C. E. G.
University of Sao Paulo
Ribeirao Preto - SP, BRAZIL.

Purpose
Previous reports show decreased BOLD signal in the anterior and posterior cingulate regions of the DMN in older participants (Broyd et al., 2009). Although these are core areas in the maintenance of brain connectivity, basal areas like the hippocampus and lateral temporal cortex play a role in the default network (Greicius et al., 2004). Here, we sought to identify spatial differences in functional connectivity as seed for effective connectivity calculation. Tractography on AD patients and normal control data sets was used to identify disease-related deviations of brain structural connectivity. Our aim was to verify the relationship between functional/effective and structural variability as disease progresses.
Materials & Methods
A group of 26 elderly were recruited for this study. Mean age for experimental group was 74 years old (s.d. 4.5). Functional data gathered from a control group was used as age-paired controls for comparison of effective connectivity (n = 13, mean age 71, s.d. 7.8). Patients were diagnosed as Alzheimer patients as confirmed by a specialist examination (mean CDR = 1, mean MMSE = 16). The research protocol was approved by the local Ethical Committee and all participants signed an informed consent. Resting state functional images were acquired in an Achieva 3T MRI scanner (Philips, The Netherlands) using a noise-attenuated EPI. Tridimensional T1-weighted images were acquired for functional coregistration. Functional data were submitted to preprocessing and Independent Component Analysis (ICA) in BrainVoyager QX (Brain Innovations, The Netherlands). Procedures for group ICA are described elsewhere (Esposito et al., 2005). Granger causality processing (Roebroek et al., 2005) on volumes-of-interest time courses were accomplished with seeds located in each hippocampus (Talairach coordinates +/- 21, -24,13). Granger causality maps were defined by the probability of GCM values being different from zero inside each group. These maps (p-value < 0.05, clusters > 50 voxels) were taken as an indication of whole-brain differences in effective connectivity for controls and patients.
Results
Group-wise comparison between Default-Mode Network maps showed differences in the right mesial temporal cortex (BA 28, 35,36) and dorsal attentional areas. Granger causality maps showed differences in areas related to attentional processing and auditory stimulus integration. Results point to an association between normal aging and differences in effective connectivity related to AD.
Conclusion
We identified differences between controls and Alzheimer disease patients by analyzing functional data. Data may be useful in giving indications about the progress of the disease, possibly pointing to candidate areas as markers for Alzheimer disease.

KEYWORDS: fMRI, Alzheimer disease, connectivity

In Vivo MR Spectroscopy of Bilateral Hippocampi in HIV-Seropositive or Neurosyphilis Patients at 3T

Chiu, P.[1]·Chan, Y.[2]·Chan, Q.[3]·Mak, H.[1]
[1]The University of Hong Kong, Hong Kong, HONG KONG, [2]Social Hygiene Service, Centre for Health Protection, Department of Health, Hong Kong, HONG KONG, [3]Philips Healthcare, Hong Kong, HONG KONG.

Purpose
As a result of changing sexual behaviors which led to the human immunodeficiency virus (HIV) epidemic, neurosyphilis (NS) also has experienced a worldwide resurgence and the infections are often concurrent. Mild cognitive impairment has been observed in early stages of neurosyphilis. In this study, magnetic resonance spectroscopy (MRS) was used to investigate the effect of neurosyphilis on the bilateral hippocampi of HIV-positive patients.
Materials & Methods
Experiments were performed on 12 cognitively normal patients (Mini-mental-state-examination ≥ 28; age: 42 ± 12.66 years) with HIV-seropositive or neurosyphilis positive (status defined by the 2010 Sexually Transmitted Diseases Treatment Guidelines by the Centers for Disease Control and Prevention). Of the 12 patients, six were HIV-seropositive with NS, four were HIV-seropositive without NS and two were HIV-seronegative with NS. Twenty-one healthy age-matched controls also were recruited. A 3.0T MR scanner was used (Achieva, Philips Healthcare) with an 8-channel SENSE head coil. Single-voxel-spectroscopy with short echo-time (TE) 38 ms, repetition time (TR) 2000 ms was employed. Single voxels of size 2.5 cm x 1.5 cm x 1cm were placed in the left and right hippocampi with point-resolved spectroscopy (PRESS) as volume selection method. MR spectroscopy data were analyzed with offline software jMRUI version 4.0 using absolute quantification based on quantum estimation (QUEST). Choline (Cho), creatine (Cre) and N-acetylaspartate (NAA) levels were investigated with internal water as reference. Cerebrospinal fluid normalization was done. Metabolic ratios of the above metabolites also were calculated. SPSS 18.0 was employed for statistical analysis using 2-sample t-test. The level of significance was $p<0.05$.
Results
Table 1. Mean values with standard deviations of metabolites obtained from HIV patients with or without NS, NS patients with or without HIV and their respective

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

age-matched controls (NC) for left hippocampus (LH) and right hippocampus (RH).

In LH, there are significant decreases in NAA/Cr and NAA/Cho between both subject groups compared to controls. However, there are significant increases NAA/Cr and NAA/Cho in the RH in both groups compared to controls. Interestingly, distinct asymmetry of metabolic ratios was observed in both LH and RH of the diseased cohorts.

Conclusion

Because of the limited sample size, there is a high degree of overlapping in both subject groups and could surely limit the detection of any differences between the groups. However, both subject groups showed asymmetrical patterns of metabolic ratios in the left and right hippocampi compared to controls. Decrease in NAA/Cr indicates neuronal loss and such targeted cell death in the left hippocampus of both subject groups warrants further investigation in a larger cohort. Although the MMSE scores were normal in the diseased subjects, very early cognitive impairment could not be detected by these psychologic scores but might be reflected by left hippocampal metabolite derangement.

Glutamate, GABA and NAAG in Medicated Patients with Obsessive-Compulsive Disorder

Mohamed, M. A.·Puts, N.·Brasic, J.·Uy, M.·Intrapiromkul, J.·Nestadt, G.·Edden, R.·Barker, P.
Johns Hopkins University
Baltimore, MD.

Purpose

Cortical excitability reflects a balance between excitation (glutamatergic) and inhibition (GABAergic). The purpose of this study was to use magnetic response spectroscopy (MRS) to determine if the inhibitory GABAergic and the excitatory glutamatergic systems are abnormal in obsessive-compulsive disorder (OCD), and are different in patients who do or do not respond to treatment with selective serotonin reuptake inhibitors (SSRIs).

Materials & Methods

Forty OCD patients (18 females, 22 males, age range 21 to 67 years) and 20 age- and gender-matched controls were included in this study. Nineteen patients were SSRI responders, 17 were SSRI nonresponders, and four were treatment naïve. All patients fulfilled Diagnostic and Statistical Manual of Mental Disorders (DSM-IV) criteria for OCD and Yale-Brown Obsessive Compulsive (YBOCS) score. Responders were defined as patients who had a 35% or greater reduction in their YBOCS score after a 10-week trial of any appropriate SSRI. All studies were performed on a Philips Achieva 3T system using a 32-channel head coil. Subjects underwent single voxel MRS (4.0x3.0x2.5 cm voxel, TR/TE=2000/35 ms) acquired from the anterior cingulate cortex (ACC) and the basal ganglia/thalamus (BG/TH) with and without water suppression. MEGA-PRESS experiments were performed for N- acetyl aspartate (NAA) and NAA-glutamate (NAAG) and γ-amino butyric acid (GABA). Metabolites concentrations were determined using the GANNET program (gabamrs.blogspot.com) for GABA, NAA and NAAG and LCModel for glutamate (Glu), glutamine (Gln), NAA, creatine (Cr), myoinositol (mI), Gln and choline (Cho) [both glycerophosphocholine (GPC) and phosphocholine (PC)] concentrations and ratios. One-way ANOVA and t tests with correction for multiple comparisons were performed between controls, SSRI responders and nonresponders controlling for age and gender.

Results

Anterior cingulate cortex NAA and NAA+NAAG concentrations were higher in younger subjects as compared to older (P<0.006, P<0.003 respectively) with no gender differences. Basal ganglia/thalamus GPC and GPC+PC was higher in males compared to females (P<0.01, P<0.02 respectively) and showed a trend increase in their concentrations in older subjects (P<0.06, P<0.02 respectively). Obsessive-compulsive disorder patients showed lower BG/TH Glu+Gln(Glx)/Cr compared to controls (P<0.03); however, the significance was lost when age and gender were co-varied for. There were no significant differences in Glu, mI, Cho, NAA, NAAG, GABA/Cr between the 3 groups. Discussion: In this study, there were no significant differences between medicated OCD patients and controls; also no differences were found between SSRI responders and nonresponders. This is in contrast to a previous 1.5T MRS study which showed a significant decrease in orbitofrontal white matter Glx and which correlated with OCD symptom severity. Other studies have found higher CSF Glu levels in drug-naïve OCD. Furthermore, a recent 3T MRS study found that unmedicated OCD patients did not have any Glx

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

abnormalities in the medial prefrontal cortex; however, they may have decreased GABA levels.
Conclusion
The current study did not find any significant differences in compounds related to the glutamatergic or GABAergic systems (Glu, NAAG, GABA) in the ACC and BG/TH between OCD patients and controls when co-varying for age and gender. The role of MRS in OCD remains to be determined.

Diffusion Abnormalities in Corpus Callosum of Patients with Refractory Epilepsy Associated with Hippocampal Sclerosis

Lyra, K. P. d.·Chaim, K. T.·Park, E. J.·Rimkus, C. M.·Castro, L. H. M.·Leite, C. C.·Otaduy, M. C. G.
Instituto de Radiologia da Faculdade de Medicina
Sao Paulo, BRAZIL.

Purpose
Corpus callosum (CC) is the most important white matter tract that connects homologous areas of the left and the right cerebral cortex and has been implicated in propagation of epileptic activity. The goal of our study is to detect diffusivity abnormalities in specific areas of the CC in hippocampal sclerosis (HS) patients using diffusion tensor imaging (DTI).
Materials & Methods
Thirty-eight patients with medically refractory epilepsy with HS (16 right- and 22 left-sided) and 24 healthy volunteers were included. MR imaging was acquired with a 3T magnet (Philips® Achieva), including structural conventional imaging and high-resolution (2 mm x 2 mm x 2 mm with 32 gradient directions) DTI. T1-weighted volumetric images were analyzed using a specific algorithm implemented in Freesurfer software, to segment the CC in five subregions named as anterior, midanterior, central, midposterior and posterior. By using Bioimagesuite® and Fsl® softwares, fractional anisotropy (FA) and mean diffusivity (MD) maps were coregistered with segmented T1-images and then diffusion indices were obtained from each CC subregion. We considered a value of p <0,05 statistically significant.
Results
Our study showed that, when compared to controls, the FA was lowest (Figure 1) and MD (mm²/s) higher (Table 1) at posterior, mid-posterior and anterior subregions of the CC.

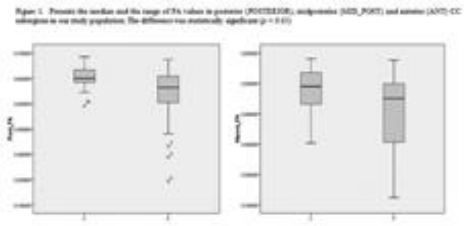

Table 1: Mean diffusivity values in patients and healthy volunteers with p values.

	Posterior	Mid-Post	Central	Mid-Ant	Anterior
Patients	1,11124339	1,17045813	0,98032463	1,05074339	1,01180550
Controls	1,00544904	1,04272488	0,93432958	0,97812492	0,94491379
p value	0,012	0,015	0,126	0,091	0,042

Conclusion
These regional diffusion abnormalities in CC are probably secondary to seizures propagation along specific pathways that are anatomically linked to epileptogenic temporal lobes like dorsal hippocampal commissure, providing pathologic changes and secondary white matter degeneration.

KEYWORDS: Diffusion tensor image, 3 T, hippocampal sclerosis

Differentiation of Pyogenic Brain Abscesses from Necrotic Glioblastomas and Cystic Metastatic Brain Tumors: Comparisons of Diagnostic Performance of Dynamic Susceptibility Contrast-Enhanced Perfusion MR Imaging before and after Mathematic Contrast Leakage Correction

Toh, C.·Wei, K.·Chang, C.·Ng, S.·Wong, H.·Chen, Y.·Wu, Y.·Peng, Y.
Chang Gung Memorial Hospital
Linkou, Taipei, TAIWAN.

Purpose
To compare the diagnostic performance of dynamic susceptibility contrast (DSC) perfusion MRI before and after mathematic contrast leakage correction in differentiating pyogenic brain abscesses from glioblastomas and/or metastatic brain tumors.
Materials & Methods
Cerebral blood volume (CBV), leakage-corrected CBV and leakage coefficient K_2 were measured in enhancing rims,

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

perifocal edema and contralateral NAWM of 17 abscesses, 19 glioblastomas and 20 metastases, respectively. The CBV and corrected CBV were normalized by dividing the values in the enhancing rims or edema to those of contralateral NAWM. For each study group, a paired t test was used to compare the K_2 of the enhancing rims or edema with those of NAWM, as well as between CBV and corrected CBV of the enhancing rims or edema. Comparisons of CBV, corrected CBV and K_2 among the three groups were done by using ANOVA. The diagnostic performance of CBV and corrected CBV was assessed with ROC curve analysis.
Results
The CBV and corrected CBV in the enhancing rim of abscesses were significantly lower than those of glioblastomas or metastases. In differentiating abscesses from glioblastomas and/or metastases, the AUC values of corrected CBV were higher than those of CBV but their differences were not statistically significant.
Conclusion
Abscesses can be differentiated from glioblastomas and/or metastases with CBV or corrected CBV measured in their enhancing rims. The diagnostic performance of corrected CBV seems to be better than CBV. But, there is no evidence that mathematic contrast leakage correction improves the diagnostic performance of CBV.

eP-18

Intracranial Manifestations of *Cryptococcus gattii* Infection

Burke, A. G.[1]·Riccelli, L. P.[1]·Allen, H. N.[2]·Anderson, J. C.[1]
[1]Oregon Health & Science University, Portland, OR,
[2]University of Wisconsin Hospitals and Clinics, Madison, WI.

Purpose
Until 1999, most human *Cryptococcus gattii* (Cg) infections were reported from Australia and other tropical and subtropical regions, including parts of Africa, Asia, the Mediterranean, South America, and southern California. During 1999, Cg began appearing in animals and humans on Vancouver Island and, beginning in 2004, among mainland British Columbia residents who had no exposure to Vancouver Island. The two human infections reported from Oregon in 2004 and 2005 were from Cg. Neither patient had traveled to Vancouver Island or any other known Cg-endemic area. Risk factors for Cg infection in the United States appear to include both immunocompromised and exposure to specific regions of environmental fungal colonization. Cryptococcus gattii infections in Australia have been shown to have higher rates of mass-like lesions than *Cryptococcus neoformans* (Cn), and similar findings have been reported anecdotally in British Columbia and the U.S. Pacific Northwest. These mass-like lesions in immunocompetent patients may be easily confused with intracranial neoplasm, particularly when the clinical index of suspicion for infection is low. This study evaluates the initial intracranial MR imaging findings of Cg infections in order to establish the incidence of Cg cryptococcoma formation and to characterize potential distinguishing characteristics from Cn infection.
Materials & Methods
Imaging studies from 62 patients with Cg infection between November 2004 and February 2012 were obtained from the Oregon Public Health Department, of which 23 patients had MR brain imaging at the time of initial diagnosis. MR brain images were de-identified and three fellowship-trained neuroradiologists independently reviewed the images and cataloged intracranial findings. The study received IRB approval from the Oregon Public Health Department and an IRB waiver from Oregon Health & Science University.
Results
Twenty-two of 23 (96%) of initial MR brain examinations exhibited pathology. Nodules were present in 11 cases (50%), ranging in size from 3 mm to greater than 30 mm in diameter, with eight of these 11 having cyst-like, nodular enlargement of the basal ganglia perivascular spaces. Cyst-like basal ganglia lesions were less likely to enhance than parenchymal nodules. Parenchymal nodules greater than 25 mm diameter occurred in three cases and showed mass-like characteristics with two of these three cases showing heterogeneous enhancement of the lesions. None of the nodules or masses showed diffusion restriction. Leptomeningeal involvement included FLAIR signal abnormality in three cases, nodular enhancement in one case, and smooth enhancement in one case. None of the patients showed hydrocephalus, intraventricular nodules, or pachymeningeal abnormalities.
Conclusion
Intracranial manifestations of Cg infection in this study of patients in Oregon since 2004 range from leptomeningeal enhancement to cystic dilatation of basal ganglia perivascular spaces to large enhancing, solid masses (cryptococcomas). Given the increasing number of Cg infections in the Pacific Northwest and the likelihood of infected both immunocompromised and immunocompetent patients initially presenting with intracranial cryptococcomas that mimic neoplastic processes, Cg infection should be increasingly considered as a differential diagnosis in patients initially thought to have intracranial neoplasm to expedite diagnosis and treatment.

Assessment of Deep Gray Matter Volume in Patients with Neuromyelitis Optica

Miraldi, F.·Rueda, F.·Alves-Leon, S. V.·Gasparetto, E. L.
Federal University of Rio de Janeiro
Rio de Janeiro, BRAZIL.

Purpose
Neuromyelitis optica (NMO) is a common demyelinating disease with spinal cord and optic nerve injury. Recently, brain involvement has been described, including typical lesions, normal appearing white matter widespread damage and even some cortical compensations for these structural damage. White matter loss associated with cognitive impairment already has been described, but the deep gray matter (DGM) was poorly studied. Our aim is to evaluate DMG volume in NMO using advanced neuroimaging techniques.
Materials & Methods
The study population included 27 patients with NMO spectrum, including neuritis optica and/or myelitis (18 female, 38 mean age) and 17 controls (13 female, 42 mean age) with no brain lesion on MRI or neurologic disorder. MR imaging of the brain was conducted on a 1.5T scanner using T1WI 3D. Then, FIRST, part of FSL4.1 (FMRIB, Oxford, UK) was applied as a postprocessing software for calculation of volume of the hippocampus, amigdalas, putamen, thalamus and caudate nucleus. Statistical analysis included the Kolmogorov-Smirnov test to evaluate the normal distribution of the values and two-tailed paired Student's *t*-test for the comparison of DGM volumes. A *p*-value equal or less than 0.05 was considered statistically significant.
Results
The comparison between DGM volumes in NMO and controls were respectively: left thalamus (7148 cm^3 vs. 7335 cm^3, p = 0.33), right thalamus (6988 cm^3 vs. 7090 cm^3, p = 0.42), left caudate (3308 cm^3 vs. 3236 cm^3, p = 0.91), right caudate (3219 cm^3 vs. 3308 cm^3, p = 0.50), left putamen (4480 vs. 5048 cm^3, p = 0.07), right putamen (4372 cm^3 vs. 4911 cm^3, p = 0.08), left hippocampus (3526 cm^3 vs. 3755 cm^3, p = 0.20), right hippocampus (3591 cm^3 vs. 3913 cm^3, p = 0.06), left amigdala (1310 cm^3 vs. 1254 cm^3, p = 0.73) and right amigdala (1277 cm^3 vs. 1265 cm^3, p = 0.79).
Conclusion
No significant difference was verified in the comparison between DMG volumes in NMO and controls, which is in agreement with the predominant white matter involvement in NMO as well as the absence of cortical gray matter findings using 7.0 T MRI. The NMO mechanism of pathogenesis might somehow preserve gray matter from damage.

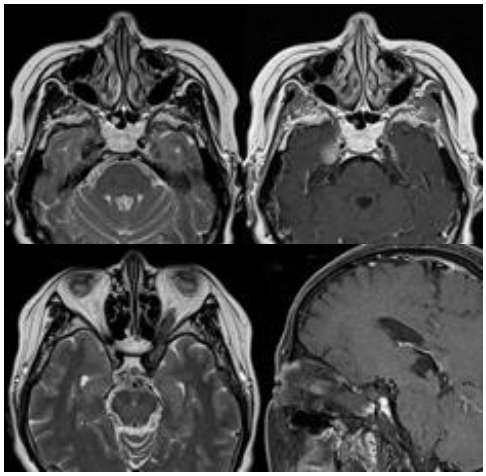
IgG4-Related Inflammatory Lymphproliferative Disease Involved Intracranial as well as the Head and Neck: Imaging Findings and Clinical Features

Kawamura, Y.·Nakaji, S.·Kikuchi, Y.·Sezaki, T.
Kameda Medical Center
Chiba, JAPAN.

Purpose
IgG4-related disease has been encountered and diagnosed such as autoimmune pancreatitis (AIP), retroperitoneal fibromatosis (RF), and sclerosing cholangitis that may involve the head, neck, and brain and the radiologic features and clinical characteristics of IgG4-related disease are discussed.
Materials & Methods
Five patients with autoimmune disorders were evaluated for head and neck lesions by MDCT (Toshiba, Aquilion 64) and MRI (SIEMENS, Avanto 1.5T). Patient 1: 61-year-old woman with RF, complained of right orbital discomfort. Patient 2: 67-year-old man with RF and patient 3: 62-year-old woman with AIP revealed bilateral painless salivary glands swelling. Patient 4: 76-year-old man with RF, and suspicious sclerosing cholangitis evaluated for orbital mass. Patient 5: 73-year-old man with RF, complained of chronic headache.
Results
In patient 1, MRI demonstrated homogeneously enhancing soft-tissue mass involving the skull base (Figure 1) along with the second and the third divisions of right trigeminal nerve. In patients 2 and 3, CT and MRI showed symmetric enlargement of salivary glands with homogeneous enhancement. In patient 4, hypointensity lesion in left infraorbital canal on T2-weighted images was seen (Figure 2). In patient 5, MRI demonstrated the dural thickening and enhancement.



Discussion
Recent study indicated that the autoimmune disorders affecting the lacrimal and salivary glands, Mikulicz disease, was IgG4 involvement in their pathogenesis. Tthe lacrimal and salivary swelling without symptom was seen in

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

patients 2, 3 and 4 during the clinical followup for IgG4-related disease. Soft tissue mass extended along meninges and the cranial nerves such as the trigeminal nerve. Symptoms are not severe - even MRI and CT show marked abnormality. In the majority of cases, steroid therapy is effective.

Conclusion

Careful interpretation of MRI is helpful to suspect the uncommon IgG4-related disease and to lead the IgG4 measurement as well as to reduce the risk of the invasive biopsy planning.

Chronic Lymphocytic Inflammation with Pontine Perivascular Enhancement Responsive to Steroids: Case Report

Le, N. T.·Buckingham, C. L.
Vanderbilt University Medical Center
Nashville, TN.

Purpose

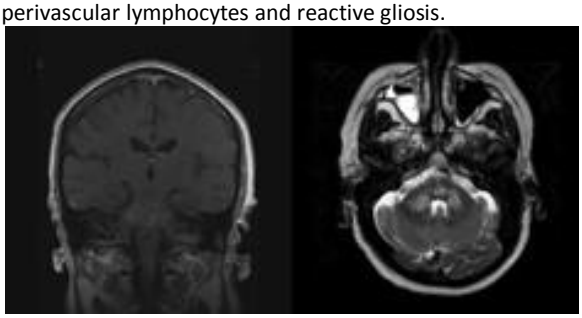
Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS) was first described by Pittock and colleagues in 2010, and a follow-up study on long-term outcome by Taieb and colleagues was published in 2012. CLIPPERS is a distinct steroid-responsive brainstem encephalitis with characteristic MRI findings. It has been proposed that once other diagnoses have been excluded, CLIPPERS can be diagnosed and treated based solely on clinical and radiologic findings without pathologic confirmation. We report three cases to further support that CLIPPERS, though new, is a definable inflammatory CNS disease.

Materials & Methods

We reviewed the medical records and imaging studies of three patients diagnosed with presumed CLIPPERS.

Results

Case 1: A 36-year-old female presented with left-sided weakness, right vision loss, and speech difficulty for six months. Brain MRI showed ill-defined T2-hyperintensity in the middle cerebellar peduncles, pons with small areas of enhancement in the pons. The patient received five days IV methylprednisolone with marginal improvement in the left-sided weakness. Case 2: A 62-year-old male presented with three months of falls and diplopia. Exam revealed lurching gait, hip flexor weakness, dysmetria, and horizontal nystagmus. Brain MRI showed T2-hyperintensity and patchy enhancement in the middle cerebellar peduncles, pons, and the cervicomedullary junction. The patient was treated with five days IV methylprednisolone. He had significant improvement with almost complete resolution of diplopia, nystagmus, dysmetria, ataxia and weakness. Follow-up MRI showed interval improvement. The patient is currently on long-term steroids and Imuran to prevent relapse. Case 3: A 53-year old male presented with numbness in the right face and body, and weakness in the left leg. MR imaging showed small ring-enhancing nodules with surrounding T2-hyperintensity centered in the left middle cerebellar peduncle. He improved after one dose of IV steroid, and was later treated with additional courses of steroid. Due to progression on MRI, biopsy was performed showing perivascular lymphocytes and reactive gliosis.



Conclusion

The clinical presentation and MRI findings in these patients with presumed CLIPPERS are similar to those previously described. Most reported cases involve the pons and middle cerebellar peduncles with linear and punctuate enhancement. Many cases have supratentorial involvement or myelitis and some required biopsy to exclude other etiologies. Ideally the diagnosis could be made based on clinical and imaging features. Awareness on the part of radiologists will aid the early diagnosis and treatment of CLIPPERS. More experience will be required to establish diagnostic criteria.

KEYWORDS: Brain abnormalities, Autoimmune, CLIIPPERS

eP-22

Imaging of Meningiomas on 3D FLAIR at 3T MR Imaging

Enokizono, M.[1]·Morikawa, M.[1]·Ideguchi, R.[2]·Uetani, M.[1]·Horie, N.[1]·Matsuo, T.[1]·Nagata, I.[1]·Hayashi, T.[1]·Honda, S.[1]
[1]Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, JAPAN, [2]Nagasaki Municipal Hospital, Nagasaki, JAPAN.

Purpose

FLAIR imaging after contrast medium injection has been shown to be an efficacious method, especially in the delineation of meningeal lesions including meningoencephalitis and leptomeningeal metastases. The purpose of this study is to evaluate the usefulness of noncontrast-enhanced (NE) and contrast-enhanced (CE) 3D FLAIR imaging for meningiomas at 3T MRI.

Materials & Methods

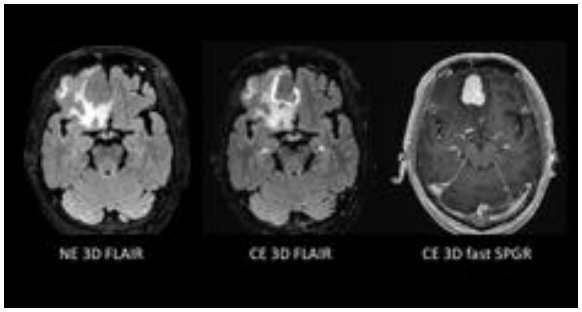
The subjects are 20 patients with intracranial meningioma who underwent tumor excision and histologically confirmed. Two neuroradiologists retrospectively evaluated the preoperative MRI findings including tumor size, the characteristics of tumor-brain interface, the

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

degree of peritumoral brain edema, and rim enhancement (RE) compared with CE 3D fast SPGR. The vascular supply also was evaluated from the preoperative digital subtraction angiography (DSA). Neurosurgeon who had performed the surgery evaluated the degree of tumor-brain adhesion during surgery. In addition, we also studied five schwannomas, also common extra-axial tumor, which underwent tumor excision.

Results

Rim enhancement was observed in 18/20 meningiomas (90%) on CE 3D FLAIR, which exhibited a high signal intensity compared to the tumor parenchyma, while in 9/20 meningiomas (45%) on CE 3D fast SPGR. No RE was seen in schwannomas. In meningiomas, no correlation was found between RE and other factors, including the severity of tumor-brain adhesion, histologic grading. However, RE tended to be more highlighted in the group with pial supply on DSA. The cases with severe tumor-brain adhesion demonstrated the lack of a hypointense marginal line at the tumor-brain interface on NE 3D FLAIR.



Conclusion

Rim enhancement may represent pial supplies of the tumors and be expected to be helpful to differentiate meningiomas from schwannomas. We also suggest that NE 3D FLAIR is useful MR sequence for predicting adhesion between meningioma and the brain interface.

KEYWORDS: 3 T, 3D imaging, meningioma

MR Perfusion in Gliomas Using Arterial Spin Labeling: Comparison with T2* Dynamic Susceptibility Contrast-Enhanced Technique

Cebeci, H.[1]·Buyukkaya, R.[2]·Aydin, O.[1]·Hakyemez, B.[1]
[1]Uludağ University, Bursa, TURKEY, [2]Duzce University, Duzce, TURKEY.

Purpose

Perfusion MRI with the T2* dynamic-susceptibility contrast (DSC) method is used widely to assess the perfusion of gliomas and the degree of tumor angiogenesis. Arterial spin labeling (ASL) is a relatively new, noncontrast perfusion MRI method which uses magnetically labeled arterial blood water protons as an endogenous tracer of flow. The aim of our study was to evaluate efficiency of perfusion in gliomas using ASL and comparison of ASL method with T2* DSC perfusion MRI.

Materials & Methods

Our study included 17 male and 16 female patients who were diagnosed as primer glial tumors between August 2011 and October 2012. Seventeen tumors were glioblastomas, two each were grade 3 oligodendroglioma, one each was grade 3 astrocytoma, four each were grade 2 oligodendroglioma, nine each were grade 2 astrocytoma. All arterial spin labeling and T2* DSC perfusion MR imaging studies were performed on a 3T MR imaging system (Achieva 3.0 Tx; Philips, Best, The Netherlands) by using a 32-channel head coil. Arterial spin labeling technique was performed with pseudocontinuous arterial spin labeling (PCASL). T2* DSC MRI was performed for all tumors by using a first-passage gadopentetate dimeglumine T2*-weighted gradient-echo single-shot echo-planar sequence followed by conventional MRI. Cerebral blood flow (CBF) and cerebral blood volume (CBV) maps were created from PCASL and T2*DSC, respectively. Relative signal intensity (SI) on PCASL images and rCBV value on T2*DSC perfusion maps were measured. The quantitative measures of the lesions were obtained by dividing the values obtained from the normal contralateral hemisphere. One observer placed region of interest (ROI) within solid tumor components where it was thought that high perfusion values would be found; he also placed ROI in the contralateral reference brain on ASL and T2* DSC maps. For statistical analysis Mann-Whitney testing was carried out. A p value of less than 0.05 indicated a statistically significant difference. The correlation between PCASL and T2*DSC and glioma grade was assessed using Pearson correlation analysis.

Results

Thirty-three target lesions (1 lesion per patient) in 33 patients were evaluated. Twenty-two of of lesions were high-grade, 11 each were low-grade lesions according to WHO classification. Signal intensity value on PCASL and rCBV on T2*DSC perfusions were significantly higher for high-grade glial tumors than low-grade tumors ($p<0.001$). There was correlation between signal intensity on PCASL and rCBV on T2*DSC perfusion (Pearson correlation = 0.783, $p < 0.001$).

Conclusion

Arterial spin labeling is a noncontrast perfusion MR imaging method, as an alternative to T2* DSC perfusion. Arterial spin labeling technique is useful in the preoperative assessment of the histopathologic grade of gliomas.

KEYWORDS: Arterial spin labeling, Dynamic susceptibility contrast-enhanced, glioma

Utility of Proton MR Spectroscopy in Differentiating Atypical Primary Central Nervous System Lymphoma from Tumefactive Demyelinating Lesions

Kim, S.[1]·Lu, S.[1,2]·Kim, D.[1]·Kim, H.[1]·Choi, C.[1]·Lim, Y.[1]
[1]Asan Medical Center, Seoul, KOREA, REPUBLIC OF, [2]The First Affiliated Hospital of Nanjing Medical Univerisity, Nanjing, CHINA.

Purpose
Primary central nervous system lymphomas (PCNSLs) usually can be differentiated from tumefactive demyelinating lesions (TDLs) by using conventional MRI, perfusion MRI and proton magnetic resonance spectroscopy (^{1}H-MRS). However, when PCNSLs show atypical MR features, it is often very difficult to differentiate from TDLs and the role ^{1}H-MRS in differentiating between the two conditions is not known well. This study aimed to investigate the usefulness of ^{1}H-MRS in differentiating PCNSLs with atypical MRI features from TDLs.
Materials & Methods
Twenty PCNSLs with atypical MRI features and 21 TDLs were enrolled in this study. Inclusion criteria for atypical MRI features of PCNSLs were necrosis (n = 4), hemorrhage (n = 5), ring enhancement (n = 4), patchy infiltrative enhancement (n = 11), streaky enhancement (n= 3) or absent contrast enhancement (n = 2) with more than one pattern in some cases. Primary central nervous system lymphomas with typical nodular enhancement pattern were excluded. All PCNSLs and six TDLs were histopathologically confirmed while 15 TDLs were clinically diagnosed. In all cases ^{1}H-MRS obtained with single voxel, intermediate TE (144 ms) point-resolved spectroscopy (PRESS) technique were available and retrospectively analyzed. Metabolites assessed were Choline (Cho), Creatine (Cr), N-acetyl-aspartate (NAA), lipid and lactate. Cho/Cr and Cho/NAA ratios were calculated. Lipid and/or lactate peak (lip-lac) was assessed visually and categorized into five grades by comparing the height of the peaks with that of Cr peak. Proton magnetic resonance spectroscopy findings were compared between the atypical PCNSLs and TDLs. Thresholds were selected with receiver operating characteristic (ROC) curves.
Results
Discrepancies between atypical PCNSLs and TDLs were found in Cho/Cr ratio ($P < 0.01$) and Cho/NAA ratio ($P < 0.01$). Lip-lac grade also was higher in atypical PCNSLs than in TDLs, but the difference was not statistically significant ($P = 0.054$). However, high lip-lac grades (> grade 3) were observed mainly in atypical PCNSLs (6/7) and only in one necrotic TDL (1/7). Lymphoma rather than TDL was suggested when Cho/Cr ratio was more than 2.45 (sensitivity 70.0, specificity 71.4), or Cho/NAA ratio was more than 1.75 (sensitivity 90.0, specificity 76.2). In two cases of nonenhancing PCNSLs ^{1}H-MRS revealed spectrums similar to those of TDLs.
Conclusion
Proton magnetic resonance spectroscopy seems to be useful for differentiating PCNSLs with atypical MRI features from TDLs. Cho/NAA and Cho/Cr ratios were significantly higher in PCNSLs than in TDLs and lip-lac grade showed a tendency to be higher in PCNSLs.

Diffuse Gliomas: Does Perfusion and Diffusion MR Imaging Correlate with Overall Survival?

Ramos, A.·Hilario, A.·Perez Nuñez, A.·Salvador, E.·Hernandez Lain, A.·Lagares, A.·Sepulveda, J.
Hospital Universitario 12 de Octubre
Madrid, SPAIN.

Purpose
Diffuse gliomas comprise the second most common primary CNS neoplasms. The prognosis for this heterogeneous group of tumors is determined mainly by histologic grade. The aim of this work is to evaluate the relationship between rCBV and ADC values with overall survival in a group of patients with diffuse gliomas.
Materials & Methods
We conducted a retrospective analysis of 162 histologically confirmed diffuse gliomas. The samples were classified as low-grade and high-grade according to the 2007 WHO Classification of Tumors of the CNS. Dynamic contrast-enhanced T2*-weighted GE EPI were acquired during the first pass of a gadolinium contrast agent. On the color-coded rCBV maps, we selected the maximum rCBV for quantitative analysis. Diffusion-weighted imaging included an axial single-shot SE EPI sequence (b=1000 s/mm^2). Five circular ROIs were placed over the whole tumor to select the region of minimum ADC. The end point of the study was overall survival, which was measured from the date of initial diagnosis to the last follow-up visit or death. To simplify the analysis, rCBV and ADC values were classified as low or high based on a cut-off value obtained from the ROC curves. This cut-off value was ≥1.74 for rCBV and ≤1.185.10^{-3} mm^2/s for ADC. Each of the parameters (histologic grade, rCBV and ADC) was first evaluated univariately by constructing probability curves according to the Kaplan-Meier method and comparing them by the log rank test. The cut-off level chosen for overall survival was their median value. Variables achieving a p value of less than 0.05 in the univariate analysis, together with histologic diagnosis, subsequently were introduced in a multivariate regression analysis (Cox model).
Results
The median survival was 38 months for grade III and 14 months for grade IV gliomas. Analyzing the rCBV values, the median survival was 50 months for low perfusion gliomas and 12 months (9.2-14.81) for high perfusion (rCBV≥1.74) tumors (p=0.001). According to the ADC values, tumors with ADC≤1.185.10^{-3} mm^2/s had a median

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

survival time of 12 months (9.22-14.78) ($p<0.001$). When we considered the group of high-grade gliomas, tumors with high perfusion values had a median survival of 11 months, while those gliomas with rCBV<1.74 had a median survival time of 50 months. If we classified tumors on the basis of the cell type, we found that median survival of astrocytomas differs significantly depending on the ADC and rCBV values. In astrocytomas, rCBV≥1.74 and ADC≤1.185.10^{-3} mm^2/s values correlated to a worse prognosis. In oligodendrogliomas, ADC and rCBV values did not have a significant relationship to overall survival. In the multivariate regression analysis we found that rCBV predicts the overall survival of diffuse gliomas regardless of histologic grade.

Conclusion

Although the survival of diffuse gliomas is determined by tumor histology, we have demonstrated that rCBV predicts the overall survival of diffuse gliomas regardless of histologic grade. In our series, perfusion and diffusion MRI correlated to patient overall survival. High-grade gliomas with high perfusion values experienced a worse outcome. The median survival of astrocytomas differed significantly depending on the ADC and rCBV values.

Differentiating Grade II from Grade III Nonenhancing Astrocytomas and Oligodendrogliomas Using Arterial Spin Labeling Perfusion MR: Comparison of Cerebrovascular Reactivity to Acetazolamide - Initial Experience

Lee, J. S.[1]·Wang, S.[1]·Mohan, S.[1]·Melhem, E. R.[2]
[1]Hospital of the University of Pennsylvania, Philadelphia, PA, [2]University of Maryland Medical Center, Baltimore, MD.

Purpose

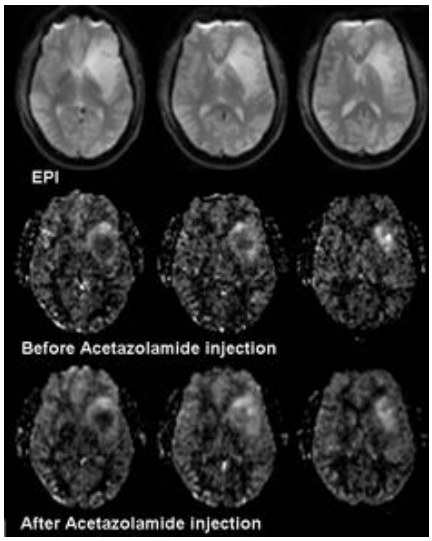
While contrast-enhanced MRI is a valuable tool in assessing tumor malignancy, a significant proportion of gliomas do not enhance. Assessment of the histologic grade of nonenhancing gliomas may be aided by evaluation of the cerebrovascular reserve (CVR), a measure of the degree of cerebral perfusion increase in response to a cerebral vasodilator. We hypothesize that higher grade gliomas will have lower CVR compared to lower grade gliomas due to greater metabolic demand. Therefore the reactivity of tumor vessels to vasodilators may provide a noninvasive marker of malignancy grade. Acetazolamide is a carbonic anhydrase inhibitor that acts as a cerebral vasodilator and is known to increase cerebral blood flow (CBF). In this study, we evaluate CBF changes after acetazolamide injection in patients with nonenhancing brain tumors, and determine if there is a correlation between tumor grade and CBF changes.

Materials & Methods

Four patients (ages 31-64 years, 3 males, 1 female) with nonenhancing astrocytomas or oligodendrogliomas were included in this study. A pseudo-continuous ASL sequence was used for the perfusion scan. Interleaved images with and without labeling were acquired using a spin-echo EPI sequence. Using a 3T Siemens TrioTim, the sequence parameters were as follows: TR/TE = 4000/28 ms, FOV = 220 x 220 mm^2, number of sections = 16, slice thickness 5 mm, matrix = 96 x 96, labeling delay = 1200 ms, labeling duration = 1500 ms. Total acquisition time was 5:32 minutes. Arterial spin labeling was acquired before and after injection of 1g of acetazolamide IV. The raw ASL data were realigned, smoothed, and labeled, and control scans were subtracted to obtain CBF data. A 3D mask was drawn over the FLAIR abnormality. Difference of CBF values before and after acetazolamide was injected was computed.

Results

One patient with pathology proven Grade II oligodendroglioma demonstrated modest increase of CBF (2 to 3%) after acetazolamide administration (Figure1). In contrast, the remaining three patients with Grade III astrocytomas all demonstrated no significant difference in CBF.



Conclusion

Our preliminary results demonstrate the feasibility of using acetazolamide to evaluate the status of CVR in nonenhancing astrocytomas. Low-grade gliomas tend to have higher cerebrovascular reactivity compared with high-grade gliomas. A larger number of patients will be required to draw definitive conclusions regarding the relationships between tumor grade and vascular reactivity.

KEYWORDS: Astrocytoma, Cerebrovascular reserve, acetazolamide

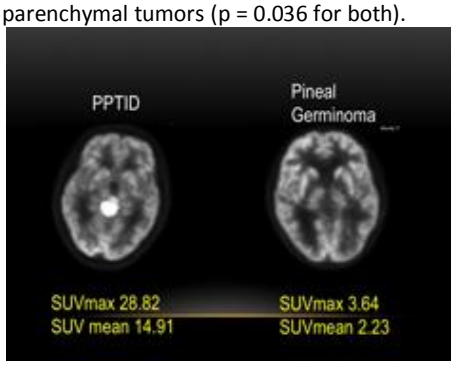
FDG-PET Imaging for Diagnosis of Pineal Parenchymal Tumors and Germinoma

Kakigi, T.
Kyoto University Graduate School of Medicine
Kyoto, JAPAN.

Purpose
Our aim of this study was to evaluate if it is possible to identify histologic types of pineal parenchymal tumors, which are including pineocytoma, pineal parenchymal tumor with intermediate differentiation (PPTID) and pineoblastoma, and to differentiate pineal parenchymal tumors from germinomas using FDG-PET imaging.
Materials & Methods
We enrolled eight patients who had FDG-PET imaging with histologic verification of pineal parenchymal tumors (five patients) and germinomas (three patients) retrospectively from July 2008 to June 2012. We measured SUVmean and SUVmax of tumors and analyzed them using Mann-Whitney U test.
Results
No significant correlation was found between FDG uptake and tumor grading of pineal parenchymal tumors. However, we found a significant difference between pineal parenchymal tumors and germinomas. SUVmax and SUVmean of germinomas were less than those of pineal parenchymal tumors (p = 0.036 for both).



Results of Mann-Whitney test for SUVmean

	PPTmean	Gmean
No.	5	3
Lowest Value	4.73	2.23
Highest Value	14.91	3.36
Median	5.56	2.88

Results of Mann-Whitney test for SUVmax

	PPTmax	Gmax
No.	5	3
Lowest Value	6.51	3.64
Highest Value	28.82	4.09
Median	7.72	3.78

Conclusion
FDG-PET imaging could not differentiate the histology among the pineal parenchymal tumors. However, we proved the diagnostic utility of FDG-PET imaging to differentiate between pineal parenchymal tumors and germinoma.

KEYWORDS: Pineal cell tumor, Germinoma, FDG-PET/CT

Precontrast and Postcontrast Susceptibility-Weighted Imaging Grading Performance in Intra-Axial Brain Lesions

Aydin, O.[1]·Buyukkaya, R.[2]·Cebeci, H.[1]·Hakyemez, B.[1]
[1]Uludağ University, Bursa, TURKEY, [2]Düzce University, Duzce, TURKEY.

Purpose
It has been reported that susceptibility-weighted imaging (SWI) may be use for grading brain tumors. The purpose of this study was to compared noncontrast susceptibility-weighted imaging (SWI) and contrast-enhanced SWI in the evaluation of intra-axial tumors.
Materials & Methods
There are different grading methods in the literature. Quantitative analysis was performed by a grading system based on the degree of intratumoral susceptibility signals (ITSS). Fifty-three patients having intra-axial tumors (n = 15 low grade, n = 19 GBM, n = 14 metastases, n = 2 lymphoma and n = 3 abscess) participated in this study. All of the patients underwent both noncontrast SWI and contrast-enhanced SWI at 3T Philips MRI system with 32-channel head coil. Venous BOLD sequence was performed. This sequence is flow-compensated T2 star-weighted 3D gradient-echo sequence. The imaging parameters are as follows: TR/TE, 21/29 ms; flip angle, 10°; FOV, 220 X 220 mm; section thickness, 0.6 mm; ETL, 1 k-space; NEX 2. Susceptibility-weighted imaging tumor grading methods are used - both SWI and contrast-enhanced SWI. The differences between the two groups were analyzed statistically.
Results
Contrast to noise ratio (CNR) of postcontrast SW images

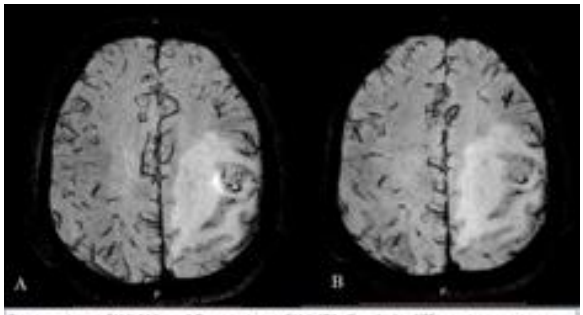
Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

higer than precontrast SWI and also high-grade tumors showed bright enhancement surrounding the tumor due to breakdown of the blood-brain barrier but there was no statistical difference between precontrast and postcontrast SWI grading (P<0.05).

TABLE 1: For semiquantitative analysis, the degree of ILSS was divided into 4 grades

Grading Method			*Patients number*
Grade 0	No ILSS	SWI	12
		CE-SWI	10
Grade 1	1-5 ILSS	SWI	9
		CE-SWI	8
Grade 2	6-10 ILSS	SWI	11
		CE-SWI	5
Grade 3	>10 ILSS	SWI	26
		CE-SWI	35

ILSS: Intralesional susceptibility signal



Postcontrast SWI (A) and Precontrast SWI (B). Grade is different same tumor

Conclusion
Susceptibility-weighted imaging at 3T and 32-channel head coil is a useful method to analyze and grade intra-axial lesions. Postcontrast SWI is not superior to precontrast SWI for grading tumors.

KEYWORDS: Susceptibility-weighted imaging, Masses

Comparison of the Value of CT Perfusion and MR Perfusion in the Differential Diagnosis of Intra-Axial Brain Tumors

Gomyo, M.[1]·Tsuchiya, K.[1]·Ohara, A.[1]·Tateishi, H.[1]·Koyanagi, M.[2]·Kobayashi, K.[2]·Nitatori, T.[1]
[1]Kyorin University, Mitaka, JAPAN, [2]Kyorin University Hospital, Mitaka, JAPAN.

Purpose
Differential diagnosis of brain tumors before surgery is important for the determination of a way of treatment as well as for the assessment of patient prognosis. Perfusion imaging is a technique that can visualize blood flow in tissue and is reportedly useful for evaluation of tumor characteristics. We comparatively assessed CT perfusion (CTP) and MR perfusion (MRP), which can visualize tumor perfusion quantitatively and semiquantitatively respectively, in the differential diagnosis of intra-axial brain tumors.
Materials & Methods
We performed CTP and MRP in patients with preoperative intra-axial brain tumor that afterwards was histologically diagnosed following resection or biopsy. CT perfusion was performed in 64 patients including high-grade glioma (HGG, n = 32), low-grade glioma (LGG, n = 8), primary central nervous system lymphoma (PCNSL, n = 5), and brain metastasis (n = 19). MR perfusion was performed in 60 patients including HGG (n = 36), LGG (n = 9), PCNSL (n = 5), and brain metastasis (n = 10). Both CTP and MRP were performed in 41 patients that included HGG (n = 23), LGG (n = 5), PCNSL (n = 4), and brain metastasis (n = 9). In CTP, we calculated CBV, CBF and MTT ratios by dividing CBV, CBF and MTT values of the solid component of tumor by that of contra-lateral normal white matter. In MRP, we visually scored CBV, CBF and MTT of the tumor by comparing with the contra-lateral normal white matter. We made comparison of perfusion measurements between CTP and MRP along with comparison among tumor groups.
Results
At both CTP and MRP, HGG and brain metastasis were higher in CBV and CBF than LGG and PCNSL, and brain metastasis was higher in MTT than HGG and LGG. At CTP, PCNSL was higher in CBV and MTT than LGG and higher in MTT than HGG.
Conclusion
Cerebral blood volume and CBF are of value to distinguish between HGG or brain metastasis and LGG or PCNSL, and MTT is useful to distinguish between HGG and brain metastasis at both CTP and MRP. On the other hand, CBV and MTT at CTP can distinguish between PCNSL and LGG.

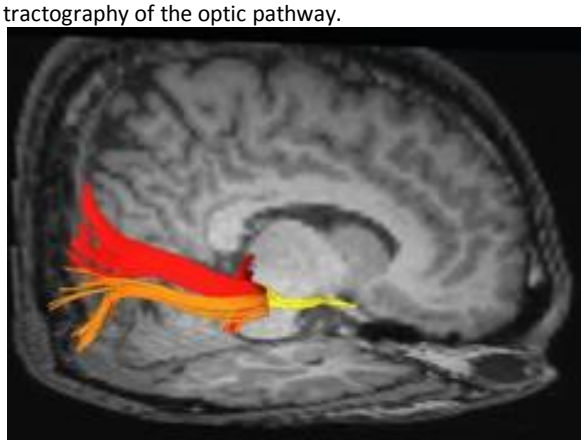
Diffusional Kurtosis Imaging of the Optic Pathways between Multiple Sclerosis and Neuromyelitis Optica

Yoshida, M.[1]·Hori, M.[1]·Yokoyama, K.[1]·Suzuki, M.[1]·Kamagata, K.[1]·Kyogoku, S.[1]·Kamiya, K.[1]·Sato, K.[1]·Aoki, S.[1]·Masutani, Y.[2]
[1]Juntendo University School of Medicine, Tokyo, JAPAN, [2]Graduate School of Medicine, The University of Tokyo, Tokyo, JAPAN.

Purpose
To evaluate differences in diffusional changes of the optic pathways between multiple sclerosis (MS) and neuromyelitis optica (NMO) using a new method, diffusional kurtosis imaging (DKI).
Materials & Methods
Five patients with known MS, five patients with known NMO, and five healthy volunteers participated in this study. Diffusional kurtosis imaging was performed on a 3T MR scanner. Diffusion metric maps were calculated by using the free software dTV II. FZRx (Image Computing and Analysis Laboratory, Department of Radiology, The University of Tokyo). Fractional anisotropy (FA) and apparent diffusion coefficient (ADC) maps of the conventional model and mean kurtosis (MK) maps were computed. The optic tracts (OT) and optic radiations (OR) of patients and controls were analyzed using a tract-specific analysis. The figure shows an example of tractography of the optic pathway.



Results
The MK, FA, and ADC of the bilateral OR and OT are shown in the table. The MK in the right and bilateral OT was significantly lower in the NMO group than in the MS group ($P < 0.01$). The MK was significantly lower in the bilateral OR of MS patients than of controls ($P < 0.05$). The MK in the right and bilateral OT was significantly lower in NMO patients than in controls ($P < 0.01$). The mean FA in the right and bilateral OR also was significantly decreased in NMO patients ($P < 0.05$).

The MK, FA, and ADC of the bilateral OR and OT (mean value ± SD)

	MK		FA		ADC(10^{-3} mm^2/s)	
	OR	OT	OR	OT	OR	OT
control	0.862 ± 0.080	0.623 ± 0.042	0.483 ± 0.035	0.313 ± 0.025	0.849 ± 0.127	1.355 ± 0.144
MS	0.742 ± 0.103*	0.610 ± 0.073	0.456 ± 0.022	0.336 ± 0.034	0.913 ± 0.067	1.433 ± 0.363
NMO	0.787 ± 0.077	0.488 ± 0.033**	0.417 ± 0.023*	0.316 ± 0.021	0.876 ± 0.066	1.522 ± 0.305

Conclusion
Diffusional kurtosis imaging may be a more sensitive biomarker to differentiate between MS and NMO than conventional diffusional evaluations, such as diffusion tensor imaging. Each disease produces distinctive diffusional abnormalities of the optic pathways

KEYWORDS: Diffusion kurtosis imaging, Brain white matter

Basal Ganglia Calcifications on Quantitative Susceptibility Mapping Images: Paramagnetic Susceptibility Property

Sohn, C.[1]·Kim, J.[1]·Choi, S.[1]·Yun, T.[1]·Han, M.[1]·Wang, Y.[2]
[1]Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [2]Cornell University, New York, NY.

Purpose
The majority of intracranial calcifications outside the basal ganglia are diamagnetic. One study reported that almost all calcifications of basal ganglia have paramagnetic susceptibility property in GRE phase image. But, corrected phase images or susceptibility-weighted images cannot clearly differentiate hemorrhage from calcifications that are located in basal ganglia. We demonstrate that quantitative susceptibility mapping (QSM) images can differentiate basal ganglia calcifications that have paramagnetic property from diamagnetic calcifications.
Materials & Methods
Twenty-four patients (women n = 11, mean age = 53 years) were examined with multi-echo T2*-GRE imaging. Imaging was performed at 1.5T (HDXT, GE Healthcare, Milwaukee, WI, USA) with 8-channel head coil. Quantitative susceptibility mapping was reconstructed by using morphology-enabled dipole inversion (MEDI) method.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Underlying disease processes in these patients included brain tumor (n = 11), cerebral infarction (n = 2), cerebral aneurysm (n = 2), and other (n = 8). Presence or absence of calcification was detected by visually inspecting the CT images. Intracranial calcifications (n = 71) were studied in the 24 patients. Outside basal ganglia calcifications (n = 63) and basal ganglia calcifications (n = 8) were enrolled. Susceptibility property was evaluated by using QSM in all calcific lesions.
Results
All outside basal ganglia calcifications (n = 63) had diamagnetic property (negative susceptibility), but eight basal ganglia calcifications had paramagnetic property (positive susceptibility). Even positive susceptibility signal intensity like calcification was detected at uncalcified basal ganglia (n = 7) that did not have calcific density by CT.
Conclusion
Quantitative susceptibility mapping images clearly visualized basal ganglia calcifications, which was paramagnetic.

KEYWORDS: Calcifications, Susceptibility-weighted imaging, basal ganglia

Susceptibility-Weighted Imaging: New MR Sequences in Daily Practice - A Pictorial Essay

Kang, H.
Seoul Veterans Hospital
Seoul, KOREA, REPUBLIC OF.

Purpose
Susceptibility-weighted imaging (SWI) magnetic resonance (MR) sequences are three-dimensional (3D) spoiled gradient-echo sequences that provide a high sensitivity for the detection of blood degradation products, calcifications, and iron deposits. This pictorial review is aimed at illustrating and discussing its main clinical applications.
Materials & Methods
Susceptibility-weighted imaging is based on high-resolution, 3D, fully velocity-compensated gradient-echo sequences using both magnitude and phase images. A phase mask obtained from the MR phase images is multiplied with magnitude images in order to increase the visualization of the smaller veins and other sources of susceptibility effects, which are displayed at best after postprocessing of the 3D dataset with the minimal intensity projection (minIP) algorithm. A total of 82 patients underwent MR examinations that included SWI on a 3.0T MR imager were enrolled. Among the 82 patients, 31 showed developmental venous anomaly, 11 patients showed cavernous malformation, 11 showed calcifications in various pathologic conditions, 10 showed susceptibility vessel sign, eight showed brain tumor, five showed microbleeds, two showed diffuse axonal injury, two showed arteriovenous malformation, one showed moyamoya disease, and one showed Parkinson disease.
Results
Susceptibility-weighted imaging is very useful in developmental venous anomaly and cavernous malformation, in characterizing brain tumors and degenerative diseases of the brain, in detecting cerebral microbleeds and in recognizing calcifications in various pathologic conditions. The phase images are especially useful in differentiating between paramagnetic susceptibility effects of blood and diamagnetic effects of calcium. Susceptibility-weighted imaging also can be used to evaluate changes in iron content in neurodegenerative disorders and to predict stroke evolution.
Conclusion
Susceptibility-weighted imaging is useful in differentiating and characterizing diverse brain disorders.

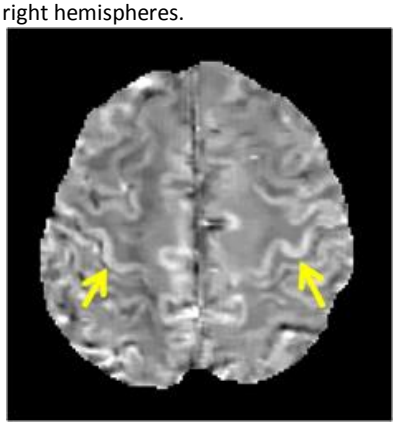
Quantitative Assessment of Susceptibility of the Motor Cortex by Using Quantitative Susceptibility Mapping

Hirai, T.[1]·Azuma, M.[1]·Kitajima, M.[1]·Yamashita, Y.[1]·Liu, T.[2]·Wang, Y.[2]
[1]Kumamoto University, Kumamoto, JAPAN, [2]Weill Cornell Medical College, New York, NY.

Purpose
Quantitative susceptibility mapping (QSM) is a novel postprocessing technique which allows the calculation of the bulk magnetic susceptibility distribution of tissue in vivo from gradient echo MR phase images. It has been proved that paramagnetic iron is the predominant source of susceptibility variations in deep gray matter. The purpose of this study was to determine the course of mean magnetic susceptibility in the motor cortex with age by using QSM.
Materials & Methods
All MR studies were performed with a multiecho gradient-echo sequence at a 3.0T Siemens scanner. The study population consisted of 40 cerebral hemispheres of 20 healthy subjects (10 females, 10 males; 26-72 years; mean age, 43 years). Quantitative susceptibility mapping was performed by using both the magnitude and phase components from all TEs in the morphology-enabled dipole inversion method. The mean of susceptibility over a region containing a hand motor area in the motor cortex was estimated on QSM images as its total susceptibility. It also was performed for the superior frontal cortex (SFC). Measurement differences were assessed by using the Student-*t* test and the *F* test; $P < 0.05$ was considered to indicate a statistically significant difference.
Results
The measured mean susceptibility with QSM was significantly higher for the motor cortex than the SFC ($P <$ 0.01). The mean susceptibility in the motor cortex and SFC

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

increased with advancing age; the mean and standard deviation of the mean susceptibility for these structures at the 5th decade was 56 ± 13 ppb and 18 ± 7.6 ppb, respectively. After the age of 50 years, an increase in mean susceptibility was subtle. With respect to latenality in the motor cortex, no differences were found between left and right hemispheres.



Conclusion

On QSM, the mean susceptibility in the motor cortex increased with advancing age. This probably reflects differences in the concentration of nonheme iron, which is consistent with the putative iron concentrations reported in the hallmark study by Hallgren and Sourander.

Advantages and Disadvantages among Noncontrast Time-of -Flight, Contrast-Enhanced Time-of-Flight and Contrast-Enhanced Dynamic Techniques in Cerebral MR Angiography: A Comparison Study

Hsieh, K.[1]·Cheung, W.[1]·Schob, S.[2]
[1]Far Eastern Memorial Hospital, New Taipei City, TAIWAN,
[2]Martin-Luther University, Halle-Wittenberg, GERMANY.

Purpose

Nowadays, magnetic resonance angiography (MRA) is one of the best imaging techniques for detecting intracranial vascular diseases, such as stenosis, aneurysm or other vascular malformations. The current routine MRA protocols include both contrast-enhanced dynamic MRA and noncontrast-enhanced time-of-flight (plain TOF) MRA. However, poor spatial resolution of the contrast-enhanced dynamic MRA is subject to miss small vascular lesions whose sizes are within a few millimeters. Besides, several studies have demonstrated that the administration of contrast agent was beneficial in MRA image for enhancing the diagnosis of intracranial vascular lesions. Because the conventional TOF MRA is not a contrast medium-based protocol, we assessed the hypothesis that contrast-enhanced TOF MRA may do better than the other two conventional MRA protocols. The purpose of this study is to compare the advantages and shortages among plain TOF, contrast-enhanced TOF and contrast-enhanced dynamic MRA and find out the most appropriate technique.

Materials & Methods

Subjects: This prospective, institutional review board-approved study with informed consent assessed MRA imaging of 30 adults with a mean age of 51 years (ranging from 24 to 64 years, 25 men and 5 women). None of them had any known CNS disease. MRI examination and analysis: Three sets of MRA images were collected on a 1.5T MR system, including noncontrast-enhanced TOF MRA, contrast-enhanced TOF MRA and contrast-enhanced dynamic MRA. Arterial image quality (AIQ) scores for 15 different medial to small-sized intracranial arteries were rated by the consensus of two radiologists with a Likart scoring system. The contrast-noise ratio of bilateral middle cerebral arterial trunks (MCAT) also was obtained. Kruskal-Wallis method of ANOVA was used to compare the IQ scores and CNRs at the three types of MRA techniques.

Results

Significantly better visualization ($p<0.001$) of intracranial arteries from the AIQ scores of contrast-enhanced TOF (20.17 ± 3.74) than plain TOF (16.63 ± 3.54) and contrast-enhanced dynamic MRA (13.10 ± 3.20) was found. There also was better MCAT CNR of contrast-enhanced TOF (61.09 ± 10.26) and plain TOF (74.11± 14.04) than contrast-enhanced dynamic MRA (43.29 ± 13.01; $p<0.05$). The CNR of contrast-enhanced TOF is less than that of plain TOF but did not reach statistical significance ($p>0.05$). The visualized intracranial veins on contrast-enhanced TOF MRA do not influence the depictions of the visualized cerebral arteries.

Conclusion

Contrast-enhanced TOF has more potential to depict the smaller intracranial vascular branches and lesions than other MRA techniques. However, the MCAT CNR obtained is comparable in either contrast-enhanced TOF or plain TOF.

Susceptibility-Weighted MR Imaging: A Better Technique in the Detection of Capillary Telangiectasia when Compared to T2*-Gradient Echo

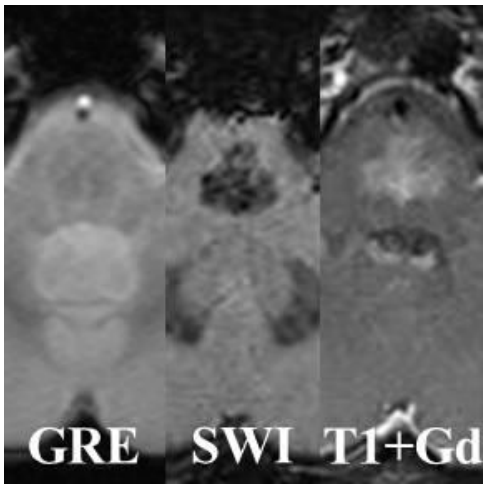
De Bruin, D. E.·Chaudhry, U. S.·Policeni, B. A.
University of Iowa Hospitals and Clinics
Iowa City, IA.

Purpose

Enhancing lesions on brain MRI can present a diagnostic quandary as both benign lesions such as capillary telangiectasia (BCT) and pathologic lesions such as demyelination or metastatic disease may appear similar. Stagnation of blood in the low-flow venous channels of BCTs results in susceptibility effect secondary to the increase in local deoxyhemoglobin. Both T2*-gradient echo imaging (GRE) and susceptibility-weighted imaging

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

have been demonstrated previously as valuable in the diagnosis of BCT. Because susceptibility-weighted imaging (SWI) is more sensitive to susceptibility changes than GRE, we aim to demonstrate an increased diagnostic value of SWI compared to GRE in making the diagnosis of BCT.
Materials & Methods
We retrospectively reviewed the MR images of 17 patients with a presumed diagnosis of BCT who were examined from June 2010 to September 2012. All patients had undergone MR imaging at 1.5T with T1, T2, FLAIR, GRE, SWI, and gadolinium-enhanced T1 sequences. Lesions were evaluated for the presence or absence of signal abnormality on each particular sequence.
Results
All 17 CBTs demonstrated distinct signal-intensity loss on SWI compared to 7/17 (41%) showing signal-intensity loss on GRE. The increased frequency of detection using SWI versus GRE is statistically significant ($z = 2.85$, $p < 0.01$; $\chi^2 = 8.10$, $p < 0.01$). Six of the lesions showed signal-intensity intensity changes on T1 and/or T2 while the remaining lesions were isointense to normal brain.



Conclusion
Benign capillary telangiectasias are more conspicuous on SWI than GRE and other precontrast MR imaging. In our review, there were no cases where GRE was positive and SWI was negative. Susceptibility-weighted imaging is a valuable tool in diagnosing these benign lesions which may otherwise be occult on noncontrast MR imaging, and should serve to increase diagnostic confidence.

KEYWORDS: Susceptibility-weighted imaging, Capillary malformation

Detection of Quantitative Differences in Cerebral Perfusion Parameters in Symptomatic versus Asymptomatic Intracranial Atherosclerotic Disease Using the Bookend Technique

Korutz, A. W.[1]·Vakil, P.[2]·Hurley, M.[1]·Shaibani, A.[1]·Carroll, T. J.[1,2]·Ansari, S.[1]
[1]Northwestern University, Feinberg School of Medicine, Chicago, IL, [2]Northwestern University, Evanston, IL.

Purpose
Intracranial atherosclerotic disease (ICAD) is associated with significant morbidity. Surgical/endovascular intervention has been relegated to patients that fail optimum medical management, but there is no risk stratification scheme to identify susceptible populations prior to presenting with refractory strokes. We studied differences in quantitative cerebral blood flow (qCBF), cerebral blood volume (qCBV) and mean transit time (qMTT) measurements between vascular territories with and without acute infarcts in patients with advanced ICAD.
Materials & Methods
We retrospectively identified 10 patients (4 male, 6 female; 66 +/- 13 years old) with moderate to severe intracranial stenoses (>50% in the supraclinoid ICA, ACA, MCA or PCA) on MRA, that also underwent a quantitative SCALE DSC-MR PWI scan (Bookend technique) at presentation. Vascular territories were divided into subgroups containing acute infarcts on MR DWI versus those with no infarcts. Exclusion criteria included presumed disease from central emboli, existing encephalomacia > 50% of the volume of the vascular territory, prior angioplasty/stenting or vascular bypass on the affected side. After imaging sequences for each patient were coregistered to a standard 3-D imaging space, vascular territories were automatically segmented using a MATLAB script. In order to assess the hemodynamic parameters of viable brain parenchyma, acute infarcts as well as encephalomalacic regions related to chronic infarcts within each vascular territory were manually excluded by drawing ROIs on B1000 and T2 imaging sequences, respectively. Quantitative cerebral blood flow, qCBV and qMTT values were generated for each vascular distribution from the SCALE PWI scan and combined values were compared using a two-tailed Student's *t*-test.
Results
Ten vascular territories (1 ACA, 6 MCA and 3 PCA) were included in the subgroup with infarcts and 11 vascular territories (5 MCA and 6 PCA) were included in the infarct-free subgroup. The mean qCBF, qCBV and qMTT values for territories containing infarcts were 31.1 +/- 1.6 mL/min/100g, 3.3 +/- 0.3 mL/100g and 6.3 +/- 0.5 sec, respectively. The mean qCBF, qCBV and qMTT values for the territories without infarcts were 37.6 +/- 1.4 mL/min/100g, 4.3 +/- 0.4 mL/100g and 6.8 +/- 0.4 seconds, respectively. Differences between qCBF and qCBV values

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

were both statistically significant ($p < 0.01$ and < 0.05, respectively). Differences in mean transit time between the two experimental groups was not significant.
Conclusion
Significant differences in qCBF and qCBV exist between vascular territories with and without acute infarcts in patients with advanced ICAD. Although no significant qMTT differences exist between these two groups, values are elevated when compared to published norms. Our findings suggest that prolongation of time-based metrics alone is not an effective indicator of the risk for infarct progression in patients with advanced ICAD. Quantitative CBF and CBV values utilizing vascular territory analysis may allow the characterization of the stages of hemodynamic failure and hence detection of unstable, refractory intracranial stenoses.

Intravenous tPA Alone versus Intravenous tPA Combined with Interventional Treatment in Patients with M3 and M4 Occlusions

Carneiro, F.·Tomsick, T.·Broderick, J.·The IMS Investigators
University of Cincinnati
Cincinnati, OH.

Purpose
M3 and M4 occlusions of the middle cerebral artery (MCA) have demonstrated a better prognosis even without recanalization when compared to proximal occlusions of the more proximal anterior circulation. Moreover these lesions are technically more difficult to treat by interventional means with lower rates of recanalization and probably more prone to complications related to the interventional procedure. The purpose of this study was to preliminarily compare the outcomes of bridging therapy (IV tPA plus interventional intra-arterial treatment) versus IV tPA alone in subjects enrolled in the Interventional Management of Stroke (IMS) I,II studies that presented with M3 and M4 occlusions. Data from IMS III Trial also will be presented.
Materials & Methods
All subjects received 0.6 mg/kg of IV tPA before cerebral DSA. Sixteen subjects demonstrated M3 and M4 occlusions confirmed by subsequent cerebral digital subtraction angiography (DSA). Seven subjects were treated with additional IA therapy via microcatheter, in a nonrandomized fashion according to operator preference.
Results
Sixteen subjects demonstrated M3 or M4 occlusions on postintravenous-rtPA arteriography. Additional IA rtPA treatment via standard microcatheter was performed in seven (43.7%). No additional interventional treatment was performed in nine (56.2%). The modified Rankin Scale (mRS) 0-2 outcomes in the IV/IA or IV-only groups were similar. Recanalization occurred in 42% of IV/IA-treated patients. There was no difference in the mRS 0-2 between subjects that recanalized, and those that did not. There were no symptomatic intraparenchymal hemorrhages. New occlusions in the IA-treated group occurred in one subject. There were no deaths with M3 and M4 occlusions.
Conclusion
Based on recanalization and clinical outcome, IV/IA therapy of M3 and M4 occlusions may offer no clinical benefit when compared to IV tPA itself. Interventional treatment of distal MCA occlusions has the potential to increase adverse events. Data from IMS III Trial also will be presented to support or refute these hypotheses.

Predictive Value of Positive Remodeling and Stenosis of Proximal Internal Carotid Artery for Cerebral Ischemic Lesions: Assessment of CT Angiography and Brain MR Imaging

Seo, H.[1]·Kim, J.[2]·Jin, K.[3]·Kim, H.[1]·Chung, S.[1]·Choi, S.[1]
[1]Seoul National University Hospital Healthcare System Gangnam Center, Seoul, KOREA, REPUBLIC OF, [2]Seoul National University Hospital, Seoul, KOREA, REPUBLIC OF, [3]Seoul Metropolitan Government-Seoul National University Boramae Medical Center, Seoul, KOREA, REPUBLIC OF.

Purpose
In coronary artery disease, positive remodeling of arterial wall is a well known factor related to acute coronary syndrome. However, there is lack of study in carotid artery. Therefore, the aim of this study is to assess the predictive value of positive remodeling at proximal interval carotid artery compared to stenosis.
Materials & Methods
We enrolled 2424 patients who had carotid CT angiographies from October 2003 to December 2011. We included patients who had brain MRI after CT angiography. Among these patients, we excluded patients who had neck infection/inflammation, history of head and neck cancer or hematologic malignancy, history of radiation in the neck, trauma in the neck, Takayasu's arteritis, dissection, Ehlers-Danlos syndrome or moyamoya disease. We analyzed CT angiography and brain MRI in the final 316 patients. We assessed the affected side of carotid artery, carotid artery diameter at the narrowest level, the proximal and just distal diameter of stenotic lesion, characteristics of plaque and presence of tandem lesions in the ipsilateral distal artery throughout the intracranial arteries. We also assessed presence and severity of small vessel disease, presence of borderzone infarction, lacunar infarction and large vessel disease. We also searched the reports of perfusion study, if patients had undergone brain SPECT scans or MRI perfusion studies. We assessed the lesions by their side. We defined positive remodeling index as ratio of the largest diameter at the narrowest portion and mean

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

diameter (average between proximal and just distal diameters). For grade of stenosis, we used both NASCET and ECST criteria. Chi square test, Student *t*-test and ANOVA test was performed using SPSS program. We analyzed significant factors related to brain lesion using multivariable analysis.
Results
Only 158 patients had proximal internal carotid lesions on CT angiography. There were 98 male and 60 female patients (average age 69.5 years). There were follow-up MRI scans in 98 patients. There were 93 patients with cerebral ischemic lesions, 68 patients with cerebral ischemic lesions except small vessel disease and 24 patients with borderzone infarct. There was no significant correlation between the narrowest diameter or the largest diameter at the narrowest level and mean diameter ($p>.05$). Mean diameter of carotid artery showed significant difference in patients with or without any type of ischemic lesions including small vessel disease ($p = .028$). Severity of stenosis assessed by ECST showed statistical significance in patients with any type of cerebral ischemic lesions ($p = .036$). However, only RI had statistical significance in patients who had cerebral ischemic lesions except small vessel disease ($p = .037$). In the perfusion study, perfusion abnormality was significantly different according to RI and the presence of stenosis was more than 70% in ECST criteria ($p<.042$).
Conclusion
Only RI had statistical significance in patients with cerebral ischemic lesion except small vessel disease. RI and stenosis was related to perfusion abnormality. Positive remodeling of carotid artery could be predictive factor for cerebral ischemic lesion.

KEYWORDS: Carotid plaque, Carotid artery stenosis, cerebral ischemic lesion

Comparison of 4D CT Angiography with MR Angiography in Acute Ischemic Stroke Patients with Probable Internal Carotid Artery Occlusion

Miyazaki, Y.･Mori, T.･Iwata, T.･Nakazaki, M.･Takahashi, Y.
Shonan Kamakura General Hospital
Kamakura, Kanagawa, JAPAN.

Purpose
Emergency MR angiography (MRA) can provide useful information to find the internal carotid artery (ICA) occlusion in an acute stroke setting. However, the usefulness of four-dimensional CT angiography (4D CTA) using 320-row area detector CT remains uncertain for emergency diagnosis of cerebral vasculature in acute ischemic stroke. The aim of our retrospective study was to investigate whether or not there were some differences between 4D CTA and MRA findings in acute ischemic stroke patients with probable internal carotid artery occlusion.
Materials & Methods
Included for analysis were acute ischemic stroke patients: 1) who were admitted to our institution within 24 hours of stroke onset from September 2010 to November 2012, 2) who underwent 4D CTA within 24 hours following emergency MRA on admission and 3) in whom the affected ICA absolutely was not visualized in MRA. We compared 4D CTA findings with MRA findings.
Results
During study period, 948 acute stroke patients were admitted within 24 hours of stroke onset and emergency MRA showed no visualization of the affected ICA in 75 of them. Among the 75 patients, 51 patients underwent 4D CTA following MRA. The 4D CTA demonstrated delayed antegrade flow of the affected ICA in 14 patients (27%) and the affected ICA supplied by collateral flow in eight (16%). In the rest (57%, 29/51), 4D CTA could not visualize the affected ICA at all.
Conclusion
In an acute stroke setting, 4D CTA can provide more accurate information of the affected ICA which absolutely is not visualized in MRA.

KEYWORDS: 4D CTA, Acute ischemic stroke, internal carotid artery occlusion

Assessment of Crossed-Cerebellar Diaschisis for Internal Carotid Artery Occlusion on Cerebral Perfusion MR Imaging Using Arterial Spin Labeling

Hiratsuka, Y.[1]･Kikuchi, K.[1]･Yokoyama, R.[1]･Mochizuki, T.[1]･Miki, H.[2]
[1]Ehime University, Toon, JAPAN, [2]Ehime Prefectural Central Hospital, Matsuyama, JAPAN.

Purpose
Crossed-cerebellar diaschisis (CCD) is thought to be caused by an interruption of the corticopontocerebellar fibers resulting in the depression of neuronal metabolism and activity displayed as the reduced blood flow in the cerebellar hemisphere contralateral to a supratentorial hypoperfusion. Several studies have reported the incidence of CCD on perfusion MRI using dynamic susceptibility contrast (DSC) technique; however, the reproducibility of CCD was lower than that previously reported in the SPECT or PET studies. Arterial spin labeling (ASL) is an alternative method of perfusion MR imaging for blood flow measurement. This technique is noninvasive and enables us to evaluate the cerebral blood flow without contrast media. Arterial spin labeling is becoming a new clinical neuroimaging tool for evaluating the intracranial blood flow dynamics. There were few reports that described CCD on perfusion MRI using ASL, and the purpose of this study is to evaluate the detectability of crossed-cerebellar diaschisis on perfusion MRI using ASL with making reference to the 123I-IMP SPECT images.
Materials & Methods

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Fifteen patients that had suspected ICA stenosis/occlusion and underwent MR examinations including ASL perfusion imaging were analyzed retrospectively. Arterial spin labeling perfusion images of MRI were acquired with a 1.5T MRI system (GE Healthcare), using a 3D ASL sequence with a pulsed continuous ASL technique and spiral fast spin-echo readout. Imaging parameters for 3D ASL were as follows: FOV: 240 x 240 mm, 128 x 128 matrix, 30 slices with a slice thickness of 4 mm and 4 mm spacing, TR/TE: 5000/10.5 ms, NEX: 3, spiral scan with 8 arms, 1450 ms of labeling time and 2025 ms of postlabeling delay. All of these patients also were scanned by 123I-IMP SPECT and those results were used as the reference. Evaluation of CCD was obtained by two radiologists on display.
Results
In 15 cases with ICA disorder, most cases had shown the decrease of CBF on the ipsilateral side of cerebral hemisphere. Three cases of those also were shown the decrease of contralateral cerebellar hemisphere, and we have estimated the lesion as the expression of CCD. In addition, CCD also was confirmed on 123I-IMP images in all three cases. On the contrary, the cases that CCD could not be detected on SPECT images were not recognized on MR perfusion images, and the results of two examinations were completely corresponding.
Conclusion
In this study, MR perfusion using ASL technique could clearly depict the CCD with high accuracy and the result was compatible with that of SPECT images. MR perfusion with ASL will be a viable alternative to SPECT to study the phenomenon and clinical consequences of supratentorial ischemic change with CCD.

Eclamptic Encephalopathy and Cerebral Hemorrhage with HELLP Syndrome

Kajlwara, Y.･Seyama, G.･Takechi, A.･Sogabe, T.
Matsuyama Red Cross Hospital
Matsuyama, Ehime, JAPAN.

Purpose
To illustrate a severe eclamptic encephalopathy (posterior reversible encephalopathy) including corpus callosum and cerebral hemorrhage with HELLP syndrome.
Materials & Methods
A 27-year-old primigravida at the 25th week of gestation presented with sudden consciousness disturbance. Her blood pressure was 190/130 mmHg. A plain CT scan of the head showed caudate hemorrhage with severe intraventricular casting and abnormal low density areas in bilateral basal ganglia and right parietal lobe. The blood examination showed HELLP syndrome with hemolytic anemia, elevated liver enzymes, and low platelet count.
Results
We performed emergency ventricular drainage for ventricle hemorrhage and emergency Caesarean delivery for HELLP syndrome. After Caesarean delivery, her blood exam data were improved dramatically. However, consciousness disturbance was persistent. MR imaging revealed multiple hyperintense lesions on T2-weighted and FLAIR images, involving bilateral basal ganglia, the subcortical white matter of the right parietal lobe, and posterior four fifth area of corpus callosum. After three weeks, her consciousness level improved gently. Transient callosal disconnection syndrome caused by corpus callosum lesion occurred during recovery. A follow-up MRI showed almost complete resolution of the abnormal signals with only slight hyperintensities on T2-weighted image in the corpse callosum.
Conclusion
Neuroimaging studies in eclampsia have shown reversible lesions of low density on CT and high-intensity on T2-weighted MRI in the subcortical white matter and basal ganglia. We reported very rare eclamptic encephalopathy case including corpus callosum.

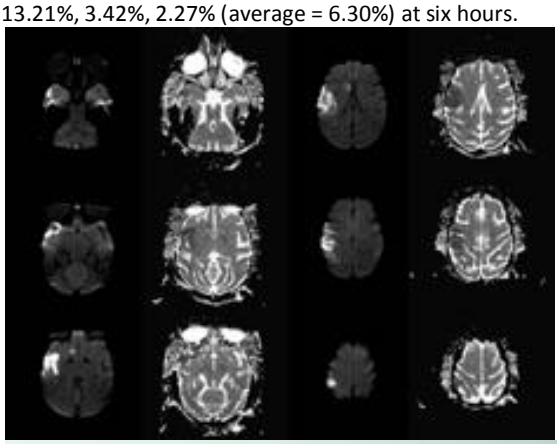
Nonhuman Primate Model of Transient Focal Stroke with Similar Level of Cerebral Ischemia

Cha, S.[1]･Lee, S.[2]･Lee, H.[3]･Lee, S.[1]･Yi, K.[1]
[1]Chung Buk National University Hospital, Cheongju, KOREA, REPUBLIC OF, [2]National Primate Research Center, Ochang, KOREA, REPUBLIC OF, [3]Chung-Ang University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Purpose
Among the research of nonhuman primates (NHPs), a few models of transient focal cerebral ischemia were documented. There is no NHP model which reproduce infarction lesions of similar characteristics such as location and temporal evolution of ADC abnormality. This is to establish a nonhuman primate (NHP) model of transient focal cerebral ischemia with perfusion-diffusion match using transient endovascular occlusion of middle cerebral artery (MCAO) branch and repeated diffusion MRIs and to observe temporal changes of diffusion abnormality.
Materials & Methods
In each of four rhesus monkeys, proximal M2 branch of right MCA were endovascularly occluded under general anesthesia. Immediately after arterial occlusion, each animal was imaged repeatedly with 3T MRI. When territorial diffusion abnormality did not grow for 30 minutes on consecutive MRIs, occluded artery was recanalized by removing intra-arterial device from the animal which remained in the MR magnet. Patency of the right MCA was confirmed on follow-up MRA. The temporal evolution of lesion volume and apparent diffusion coefficient (ADC) in the ischemic lesions were investigated.
Results

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

The duration of arterial occlusion was 50, 80, 100, 120 minutes, respectively. Focal infarction volume was initially at 30 minutes after ischemia, 35.87%, 11.15%, 8.66%, 13.71% of ipsilateral hemisphere (average = 17.35%), peak volume prior to the recanalization was 37.85%, 12.41%, 14.68%, 19.76% (average = 21.18%), respectively. After the reperfusion, in three cases, lesion volume decreased to 13.21%, 3.42%, 2.27% (average = 6.30%) at six hours.



Conclusion

Using temporary endovascular arterial occlusion, serial diffusion MRI and variable duration of transient focal cerebral ischemia, we developed a NHP model of with minimal perfusion-diffusion mismatch. This preliminary experience would lead to establish the NHP stroke model with localized hemispheric infarction of similar damage level.

Volumetric CT for the Assessment of Moderate and Severe Traumatic Head Injury: Prognostic Value and Reliability Analysis

Ramos, A.·Lagares, A.·Hilario, A.·Salvador, E.·Millan, J. M.·Fernandez Alen, J.·Gomez, P.
Hospital Universitario 12 de Octubre
Madrid, SPAIN.

Purpose

The objectives of this study are to evaluate the feasibility and reliability of volumetric CT for the initial assessment of traumatic brain injury and to determine its prognostic value in relation to other commonly used prognostic factors.

Materials & Methods

A prospective series of 210 patients suffering moderate to severe traumatic brain injury consecutively admitted to Hospital 12 de Octubre between January 2010 to May 2012 were included in the study. Patients were admitted in the ICU and were managed according to standard protocols consistent with international guidelines. All demographic and clinical variables related to prognosis were recorded at admission, as well as the development of raised intracranial pressure and the need for surgical treatment. Outcome was determined six months after injury using the Glasgow Outcome Scale. Initial and control CTs were classified by the TCDB classification and evaluated by the use of Analyze software and the volume of the different hemorrhagic lesions were calculated using region of interest volume (ROI). Also midline shift displacement was assessed, as well as cisternal effacement. The first CT scans were evaluated by two independent observers in order to assess interobserver variability. For appraising the inter-rater reliability of volumetric measurements of the different lesions evaluated as well as the total hemorrhagic volume interclass correlation coefficients (ICC) were used as well as the methodology proposed by Bland and Altman. The relation of individual hemorrhagic lesions and different prognostic factors as well as the total volume of hemorrhagic lesions in the worst CT with outcome was determined by means of Mann-Whitney U tests. Logistic regression analysis was used for predicting outcome using quantitative CT data adjusted by other prognostic factors.

Results

Interobserver reliability was high for the different traumatic hemorrhagic lesions except from traumatic subarachnoid hemorrhage (ICC = 0.6). Subarachnoid hemorrhage, subdural hematoma, intracerebral hematoma and total hemorrhagic volumes were significantly related to a worse prognosis in the univariate analysis. Total hemorrhagic volume had a higher discriminatory capacity then TCDB classification of injury after adjusting for other prognostic factors in the multivariate analysis.

Conclusion

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Quantitative CT is a novel approach for assessing lesional burden in different cerebral pathologies. Its application in head injury patients is feasible, reliable and could improve outcome prediction.

Cranio-Cervical Vascular Dissections: A Three-Year Retrospective Analysis of Distribution Patterns and Incidence Using CT Angiography as a Screening Tool at Level I Trauma Center

Chong, J. J. R.·Hanagandi, P. B.·Bessissow, A.·Chankowsky, J.·del Carpio-O'Donovan, R.
McGill University
Montreal, QC, CANADA.

Purpose
To retrospectively analyze the incidence and distribution of vertebral, carotid, extracranial, and intracranial dissections in patients presenting with blunt and penetrating head and neck trauma.
Materials & Methods
Retrospective analysis of 771 patients from January 2009 to December 2011 assessed at a tertiary academic trauma center emergency department was performed. Patients who underwent CT examinations were suspected of cervico-facial, calvarial and skull base fractures and presented with blunt, penetrating, and high velocity injuries. Examinations were evaluated for soft tissue and osseous injuries, as well as intracranial hemorrhage followed by CTA of the head and neck. All examinations were performed with 64 slice MDCT (LightSpeed VCT, General Electric) using standard parameters (120 Kvp, 300 mAs, 0.625 mm slice thickness, 25-35 cm FOV, 0.9 - 1.0 pitch, 60-75 ml nonionic iodinated contrast). Omnipaque 300 was administered intravenously with an automated pressure injector at a flow rate of 4 mL/second and scanned from the arch of aorta to the level of the corona radiata with helical acquisition and bolus tracking technique. Axial, coronal and sagittal images were reformatted at 2.5 mm slice thickness.
Results
A total of 771 patients, 498 male and 273 female, between the ages of 17 to 94 years were evaluated. Twelve definite, and 18 suspected dissections were identified of which 11 were vertebral, five were carotid, and one was intracranial. The overall incidence of vertebral versus carotid dissections was estimated to be 0.8 - 1.4% versus 0.6%. The incidence of extracranial versus intracranial dissections was 1.4 - 2.1% versus 0.1%. Incidental findings were made in an additional 43 cases, predominantly composed of atherosclerotic stenoses and intracranial aneurysms.
Conclusion
Post-traumatic cranio-cervical vascular dissections are a rare but clinically significant entity and CTA as an emergency screening tool significantly influences patient management, risk stratification and the need for any further vascular intervention in patients with post-traumatic cranio-cervical dissection.

KEYWORDS: Carotid dissection, Dissection

Imaging of Carotid Artery Plaque Remodelling

Saba, L.[1]·Raz, E.[2]·Suri, J.[3]·Suri, J.[3]·Fatterpekar, G.[2]·Piga, M.[1]
[1]AOU Cagliari, Cagliari, ITALY, [2]University of New York, New York, NY, [3]Biomedical Technologies, Pocatello, ID.

Purpose
The concept of remodelling indicates the morphologic and ultra-structural variation of a plaque in the time. Plaques change and it is possible that some determinants of instability are transitory. In this work our purpose was to understand the physiopathology of plaque remodelling and to review CT, MR and US imaging findings of this phenomenon.
Materials & Methods
Content organization: 1) To review the concept of carotid artery plaque remodelling, 2) The biomechanical effect of plaque eccentricity, 3) MR, CT, and US imaging findings of carotid artery plaque follow up that demonstrate the plaque remodelling, 4) Limits and potentialities and risk of MR, CT and US in the followup of the carotid artery plaque, 5) Presentation of relevant cases.
Results
The unique geometrical configuration and flow properties of the carotid bifurcation contribute to the formation of atherosclerotic plaque that may markedly change over time.
Conclusion
Currently, imaging techniques can identify and characterize the plaque remodelling and in particular the use of MR allows to precisely distinguish plaque components and characteristics and to identify the plaque's changes.

KEYWORDS: Carotid plaque

Assessment and Optimization of Dual Energy CT Angiography for Evaluation of Treated Aneurysms: A Phantom Study

Andre, J. B.·Perez, F. A.·Ramos, M.·Fink, K. R.·Mossa-Basha, M.·Mengesha, B.·McCallum, S.·Hippe, D. S.·Anzai, Y.
University of Washington School of Medicine
Seattle, WA.

Purpose
Conventional computed tomography angiography (CTA) is used routinely to evaluate the surgical and endovascular treatment of intracranial aneurysms, yet suffers from

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

potentially significant beam-hardening artifact and can compromise identification of residual or recurrent aneurysms. CT advancements, such as dual energy CTA (DE CTA), may help to reduce beam-hardening artifact in patients following aneurysm treatment. Using a phantom model, Gemstone Spectral Imaging (GSI) DE CTA was evaluated and optimized for the imaging of treated intracranial aneurysms.

Materials & Methods

A CTA phantom was constructed utilizing a preserved human cranium. Catheter tubing (Edwards Lifesciences, Irvine, CA) was filled with 3.5 mg iodine/mL iohexol iodinated contrast medium (350 mgI/ml; GE Healthcare Ireland, Cork, Ireland) and configured to form four orthogonal intersections to simulate a vessel and adjacent aneurysm. A medical grade endovascular coil or aneurysm clip then was placed at each of these four simulated aneurysm locations. The calvaria, tubing and coil/clip assemblies then were embedded in agar. CT data were acquired on a Discovery CT750 HD scanner (GE Healthcare, Milwaukee, WI), including baseline data acquired using standard institutional CTA parameters (140 kVp, 330 mA, 0.5:1 pitch, and rotation speed of 0.5 sec; total estimated CTDI was 72.32 mGy) and DE CTA data with parameters matched for radiation dose using fast kV-switching GSI between 40 and 140 keV (140 kVp, 630 mA, 0.5:1 pitch, and rotation speed of 0.5 sec; or 140 kVp, 260 mA, 0.5:1 pitch, and rotation time of 0.8 sec). Sets of images were generated at virtual monochromatic energy levels of 40, 60, 77, and 140 keV and evaluated by three blinded neuroradiologists for assessment of subjective image quality using the following Likert-type items: 1) extent of beam hardening artifact, 2) quality of aneurysm visualization, 3) confidence in aneurysm measurement, 4) quality of artery lumen visualization, and 5) overall diagnostic quality. Differences were evaluated with two-factor ANOVA using R 2.14.1.

Results

Sixty-eight sets of orthogonally reformatted images were evaluated. Compared to conventional CTA, DE CTA was associated with increased artifact, decreased aneurysm visualization, decreased aneurysm measurement confidence, decreased artery lumen visualization, and decreased overall subjective diagnostic quality ($p < 0.05$). Image quality differences were most apparent using a 140 keV monochromatic energy level compared to standard CTA; 40 keV monochromatic images tended to score similar to the conventional CTA, though generally somewhat lower.

Conclusion

When compared with standard CTA parameters, evaluation for residual or recurrent aneurysms with GSI-based DE CTA, using monochromatic energy levels of 40, 60, 77, and 140 keV, is associated with reduced subjective image quality. Additional optimization could be helpful to improve image quality of DE CTA for evaluating treated aneurysms.

eP-47

MR Imaging and Diffusion Tensor Imaging Markers of Brainstem Sagging in Frontotemporal Brain Sagging Syndrome

Lai, L.·Capizzano, A. A.·Kim, J.·Moritani, T.·Pinzon Jimenez, O.
University of Iowa Hospital and Clinics
Iowa City, IA.

Purpose

Frontotemporal brain sagging syndrome (FBSS) is a recently described, rare presentation of spontaneous intracranial hypotension (SIH) with features of frontotemporal dementia (FTD). The purpose of this study is to determine imaging characteristics that distinguish FBSS from classic SIH, thus shedding light on the pathophysiology of this intriguing condition.

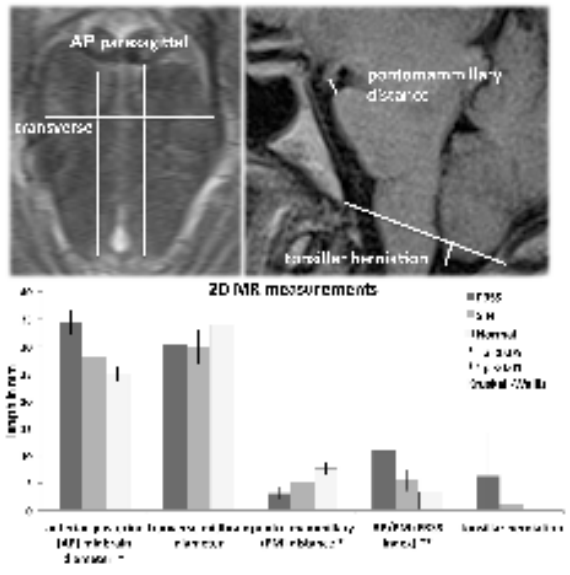
Materials & Methods

Brain MRI and DTI were compared between age- and sex-matched groups of patients with FBSS (n = 3), classic SIH (n = 5), and normal controls (n = 6). Frontotemporal brain sagging syndrome had clinical symptoms of FTD (cognitive decline and affective disorders) combined with brainstem signs and MRI findings of marked brain sagging without frontotemporal atrophy. One patient's neuropathologic exam showed no FTD. Spontaneous intracranial hypotension patients had positional headaches, low opening pressure and brain imaging consistent with SIH, but no FTD-like symptoms. AP midbrain diameter (AP) and pontomammillary distance (PM) were compared (Figure). Exploratory DTI analysis was performed by spatially transforming MRI data into a standard template and analyzed using the tract-based spatial statistics method.

Results

Symptom duration was longer in FBSS (43.7 months) than for SIH (4.2 months) ($p<0.01$). Meningeal enhancement and subdural collections occurred more frequently in SIH than FBSS ($p<0.05$). Increased anterior-posterior (AP) diameter of the midbrain and shortened pontomammillary (PM) distance were significantly different across groups ($p<0.05$) (Figure). The AP/PM ratio ("FBSS index") discriminated between patient groups without overlap. Frontotemporal brain sagging syndrome had higher FA values at the superior cerebellar peduncle and lower FA values in the cerebral peduncle ($p<0.05$) compared to controls.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Conclusion

There are significant morphologic and DTI differences between FBSS and SIH or normal controls. The FBSS index can help distinguish SIH alone from FBSS. Frontotemporal brain sagging syndrome also had longer symptom duration and fewer subdural collections and meningeal enhancement compared to SIH group. Diffusion tensor imaging suggests stretching of mesencephalic and upper brainstem neural fibers in FBSS. The Monro-Kellie doctrine explains classic SIH imaging findings of compensatory meningeal enhancement and subdural collections. Frontotemporal brain sagging syndrome is a more chronic and severe brain sagging syndrome where those compensatory mechanisms might be insufficient to prevent neural tissue stretching across the tentorial incissura. Frontotemporal brain sagging syndrome often is confused with FTD although it also includes subcortical symptoms such as hypersomnia, dysphagia and ataxia. Given the potential reversibility of FBSS, distinction from FTD is paramount.

KEYWORDS: Intracranial hypotension, Midbrain, frontotemporal brain sagging syndrome

eP-48

Relationship between MR Imaging Findings and Clinical Diagnosis in Patients with Suspected Normal Pressure Hydrocephalus

Caverzasi, E.·Santos, M.·Sha, S. J.·Geschwind, M. D.·Seider, T.·Miller, B. L.·Henry, R. G.·Hess, C. P.
University of California San Francisco
San Francisco, CA.

Purpose

Normal pressure hydrocephalus (NPH) is a poorly understood and controversial entity for which imaging plays an important role. A number of studies have posited various MRI features as supporting the diagnosis of NPH, but limited work has been done to assess the relationship between imaging findings and clinical diagnosis after evaluation by dementia specialists. In this work, we assessed the prevalence of different clinical and imaging findings in a cohort of patients referred for MRI suspicion of NPH.

Materials & Methods

We retrospectively reviewed records and brain MRI for 80 patients referred to our tertiary behavioral neurology clinic between 2005 and 2012 for suspected NPH based on MRI. Data abstracted included age, gender, presenting symptoms (cognitive deficit, gait apraxia, and/or urinary incontinence) and assigned clinical diagnosis. Patients shunted or who received other prior neurosurgical intervention were excluded, as were patients with evidence of obstructing lesions and/or absent or poor-quality MRI. Blinded to clinical information, radiologists reviewed the brain MRI closest in time to the clinical evaluation (± 6 months) for findings with a reported association with NPH, including Evans index (EI) > 0.3, callosal angle (CA) < 40°, evidence for extra-ventricular CSF obstruction (gaping sulci, narrowed vertex CSF spaces, and/or disproportionately enlarged sylvian fissures), and distended third ventricular contours (abnormal rotation of the third ventricular and chiasmatic lines, mamillopontine or mamillocommissural distance). Periventricular T2 signal also was assessed using the Fazekas scale and dichotomized as either mild (F0 or F1) or significant (F2 or F3). The prevalence of demographic features, clinical findings and imaging signs was assessed for patients diagnosed with possible NPH after clinical evaluation and compared to patients assigned alternative diagnoses.

Results

Forty-four patients were included and divided into groups with or without possible NPH based on clinical impression. All patients with possible NPH were considered for further evaluation (large volume tap, lumbar subarachnoid drain and/or ventriculoperitoneal shunt). Univariable logistic regression showed no difference in demographic variables, clinical presentation or MRI findings between the two groups (Table 1). The diagnosis of NPH was more frequent when cognitive, urinary and gait abnormalities occurred together ($p = 0.5$) or when urinary symptoms occurred alone ($p = 0.05$).

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

TABLE. Demographic, Clinical and MRI Findings		Clinical Diagnosis	
		Possible NPH	Other diagnosis
Demographic	Age (years)	76.7(+/-11)	77.8(+/-10)
	Gender (M:F)	14:10	14:06
Clinical	Cognitive deficit	1	0.9
	Urinary incontinence	1	0.6 *
	Gait apraxia	1	1
	Evans index > 0.3	1	1
MRI	Callosal angle < 40°	0.11	0.2
	CSF obstruction	0.44	0.5
	Abnormal third contour	0.4	0.6
	Significant periventricular T2	0.56	0.3
	* statistically significant		

Conclusion

Although MRI is used for the identification and referral of patients with possible NPH, individual imaging findings reported to be associated with the diagnosis may not have a significant relationship to clinical impression by dementia specialists. Further analysis and studies are needed.

KEYWORDS: NPH, MR imaging brain

Neuroradiologic Phenotype in Wernicke Encephalopathy Is Age-Related

Zuccoli, G.[1]·Crowley, H.[1]·Gallucci, M.[2]·Nardone, R.[3]·Fitzgerald, R. T.[4]·Tabarki, B.[5]
[1]Children's Hospital of Pittsburgh, Pittsburgh, PA, [2]University of L'Aquila, L'Aquila, ITALY, [3]Franz Tappeiner, Meran, ITALY, [4]University of Arkansas for Medical Sciences, Little Rock, AR, [5]Riyadh Hospital, Riyadh, SAUDI ARABIA.

Purpose

Wernicke encephalopathy (WE) is a rare neurologic disorder resulting from a vitamin B1 deficiency. Early detection and treatment is critical to this disorder because clinical symptoms can be resolved with thiamine supplementation. Brain energy requirements are age-related and thiamine is actively involved in brain energy metabolism. Based on this knowledge, we speculate that areas of high metabolic demand will have a higher rate of involvement in Wernicke encephalopathy in children than adults, therefore the neuroradiologic phenotype of Wernicke encephalopathy may be age-related.

Materials & Methods

A review of the literature was performed on October 14, 2012 using a PubMed/Ovid search of “Wernicke encephalopathy” “Wernicke-Korsakoff,” “Korsakoff Syndrome,” “Wernicke Disease,” “Wernicke-Korsakoff Syndrome,” “Wernicke Syndrome,” and “Thiamine deficiency”. The search included all ages and all studies in which MRI was part of the diagnostic process. Published images were reviewed for selective deep nuclei involvement, a finding first described by the literature in 2001.

Results

A total of 246 cases of WE described by MRI were evaluated. In the adult population, 114/216 (53%) of cases showed periaqueductal gray matter involvement. In 105/216 (49%) the mammillary bodies were involved. In 155/216 (72%) the periventricular region of the third ventricle and thalamus was involved. In 18/216 (8%) the cortex was involved. In 16/216 (7%) the basal ganglia were involved. In 3/216 (1%) the corpus callosum was involved. In 14/216 (6%) the cerebellum was involved. In 93/216 (43%) the brainstem was involved. Of the pediatric population, 15/30 (50%) of the cases showed periaqueductal gray matter involvement. In 15/30 (50%) the mammillary bodies were involved. In 20/30 (67%) the periventricular region of the third ventricle and thalamus was involved. In 7/30 (23%) the cortex was involved. In 13/30 (43%) the basal ganglia were involved. In 7/30 (23%) the brainstem was involved. In 1/30 (3%) the cerebellum was involved. No involvement of the corpus callosum was seen.

Conclusion

Our findings show that the typically affected regions: periaqueductal gray matter, mammillary bodies, and the thalamus do not differ significantly between adults and children. There is, however, a strong prevalence of striatal structure involvement in children, likely reflecting higher thiamine metabolic demands in these anatomical structures correlating with the brain maturation process.

Preliminary Cognitive Functional Imaging Study of Patients with Early Diabetes

Tian, W.[1]·Liu, X.[1]·Xie, J.[2]
[1]University of Rochester Medical Center, Rochester, NY, [2]Peking University Medical Center, 3rd Hospital, Beijing, CHINA.

Purpose

To evaluate cognitive dysfunction in early diabetes

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

patients with psychologic tests and fMRI. To analyze MR spectroscopy change in prefrontal cortex (PFC).
Materials & Methods
Twenty patients with early type 2 diabetes mellitus and 15 demographically similar, healthy subjects were enrolled. All subjects with microalbuminuria, hypoglycemia and ketonic acidosis, visible cerebral lesions on MR were ruled out. Wechsler memory scale-revised (WMS-R), trail making test A and the personality and affective states were assessed in both groups. Then nback task fMRI and single-voxel MRS with TE 30 on bilateral PFC were performed. The statistical differences of neuropsychologic tests and MRS result between the two groups were evaluated. The fMRI data were analyzed by SPM2.
Results
(1) Psychologic tests showed that the scores of cognitive tests in diabetes group were significantly lower than those in control group. Diabetic patients were more depressive and anxious than controls. (2) Functional MRI examinations revealed that the activation pattern in diabetes group was similar to the control group, but less activation in frontal, parietal lobe and cerebellar was demonstrated. There was additional activation in right temporal lobe(including inferior temporal gyrus and parahippocampus gyrus) and anterior cingulate cortex in diabetes group. (3) MR spectroscopy data showed that compared with the control group, the value of Glx/(Cho +Cr) was elevated in bilateral PFC, that the value of Cho/Cr were decreased in the right side, and that the value of NAA/Cho, Glx/Cho, Glx/Cr were elevated in the right side. Transit memory was negatively correlated with Glx/Cho (F=-0.546, p value =0.013) and Glx/(Cr+Cho) (F=-0.471, p value = 0.036). The number of errors in trail making test A was positively related to NAA/Cr.

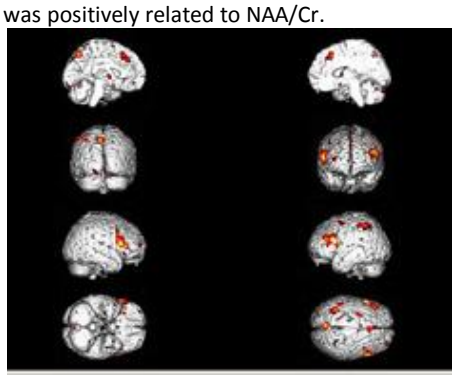

Figure: Localized brain area with decreased activation in patients group.
Conclusion
Early type 2 diabetic patients have cognitive dysfunction, especially decreased memory at verbal working memory. The fMRI using nback test shows the hypofunction in PFC, which plays an important role in cognitive dysfunction and the emotional abnormality in diabetic patients. The value of NAA in PFC is not significantly decreased. However Glx elevation may represent the disregulation of Glx metabolism and/or the neuron apoptosis caused by Glx accumulation. Increase of Glx and the degeneration of choline neuron system, which may be part of the pathophysiologic basis of PFC hypofunction.

Analysis of Association between Cerebral Microbleeds and Volume of White Matter Lesion

Saba, L.[1]·Raz, E.[2]·Suri, J.[3]·Fatterpekar, G.[2]·Piga, M.[1]
[1]AOU Cagliari, Cagliari, ITALY, [2]University of New York, New York, NY, [3]Biomedical Technologies, Pocatello, ID.

Purpose
Cerebral microbleeds (CMB), as visualized on T2*-weighted images, have been detected in patients with ischemic stroke. We hypothesize that CMB are an expression of leukoaraiosis. Our aim is to evaluate the correlation between CMB and a volumetric measure of white matter hyperintensity, as measured with a semiautomatic technique.
Materials & Methods
We prospectively analyzed 54 consecutive patients (mean age 72 ± 9 years, males 42) with carotid artery stenosis recruited at our Institution before undergoing carotid endarterectomy. The patients underwent an admission brain MRI of the brain which included T2-FLAIR, T2-SE, T2*-GE and DWI sequences. A neuroradiologist performed the evaluation of CMB (dicotomic presence/absence and number) as well as FLAIR-leukoaraiosis lesion volume using a semi-automated segmentation technique (Jim, Xinapse System, Leicester, UK). Pearson correlation was conducted to identify correlation between the CMB and the FLAIR-leukoaraiosis lesion volume. Mann-Whitney U was used to test the amount of leukoaraiosis in the subgroups CMB+ and CMB-.
Results
Among the 54 patients, 26% had CMBs. Pearson correlation found a statistically significant association between the volume of leukoaraiosis and the presence of CMB (rho = 0.377, p value 0.0005) and between the number of white matter lesions and leukoaraiosis (rho = 0.295, p value 0.0071). The Mann-Whitney U test confirmed that the amount of leukoaraiosis in the subgroup with CMB was higher compared to the subgroup without CMB (p = 0.0005) as well as the number of lesion (p value = 0.0062).
Conclusion
The presence of CMB is correlated with the volume of white matter hyperintensity, in turn associated with a higher incidence of ischemic stroke.

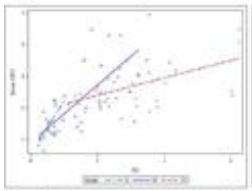
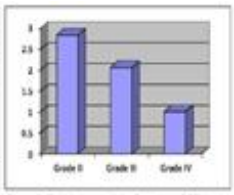
Glioma Angiogenesis, Angiogenic Switch and Perfusion Imaging: Understanding the Relationship of Tumor Blood Volume and Leakiness with Increasing Tumor Grade

Griffith, B.·Jain, R.·Khalil, K.·Nagpal, P.·Scarpace, L.·Mikkelsen, T.·Bagher-Ebadian, H.·Schultz, L.
Henry Ford Health System
Detroit, MI.

Purpose
The purpose of this study was to provide an imaging correlate to the changes occurring at the microvasculature level during the complex process of angiogenesis in gliomas. This was accomplished through the relationship of in vivo assessment of vascular parameters [i.e., tumor blood volume (cerebral blood volume, CBV) and tumor leakiness (permeability surface area product, PS)].
Materials & Methods
A total of 123 patients with pathologically proven neoplastic (n=106; WHO grade IV=45, grade III=18 and grade II=13, recurrent high-grade gliomas=30) and non-neoplastic (n=17; radiation necrosis, RN=12, tumefactive demyelinating lesions, TDL=5) lesions underwent preoperative perfusion CT (PCT). Regression analyses were done to assess the rate of change between CBV and PS and test whether these rates (or slopes) differed for the distinct lesion groups. In addition for the WHO grades, the ratio of CBV to PS was computed and compared using analysis of variance (ANOVA) methods. All statistical testing was done at the 0.05 level.
Results
The rate of change in CBV with respect to PS was highest for grade II gliomas followed by grade III and then grade IV (1.64 vs 0.91 versus 0.27, respectively) (Figure 1). The difference in rate of change was significant between grade III and IV (p=0.003) and showed a trend for grades II and IV (p=0.098). The difference between grades II and III was not significant (p=0.386). The rate of change for recurrent tumors was even smaller than the WHO grade gliomas (slope=0.14). When assessing the ratio of CBV to PS, the ratios were the highest for grade II and lowest for grade IV (Figure 2). The pairwise difference between all three groups was significant (p < 0.001 for all).





Conclusion
Gliomas have a complex and heterogeneous vasculature, relying on angiogenesis to maintain an adequate blood supply. Developing imaging methods capable of providing insight into this process is critical to better understanding these tumors. It has been shown that CBV and PS correlate with different aspects of vascular histology and hence, may change at different rates as tumors progress to higher grades. This study suggests that CBV and PS can serve as imaging correlates to changes occurring at the microvasculature level, providing an in vivo means of assessing the stepwise progression of angiogenesis. Eventual incorporation of these vascular parameters as potential biomarkers will be important to the development and evaluation of current and new therapies.

Comparison of Manually Selected Arterial Input Function and Standard Radiologic Arterial Input Function in Dynamic Contrast-Enhanced T1 MR Imaging Estimation of Tumor Kinetics Using Nested Model Selection Approach

Chwang, W. B.·Jain, R.·Nejad-Davarani, S. P.·Vanslooten, A.·Schultz, L.·Arbab, A. S.·Bagher-Ebadian, H.
Henry Ford Health System
Detroit, MI.

Purpose
The purpose of this study is to compare the results of using a standard radiologic arterial input function (SRAIF) versus a manually selected arterial input function (MSAIF) in dynamic contrast-enhanced (DCE) MR image analysis. These two AIFs were used to estimate permeability parameters such as extracellular-extravascular space volume (ve), plasma volume (vp) and forward vascular transfer constant (Ktrans) in rat brain tumors. Two contrast agents (Gd DTPA and Gadofosveset) with different molecular sizes were used.
Materials & Methods
Nine Fisher 344 female rats were inoculated intracerebrally with 9L gliosarcoma cells, and imaging was done using either gadofosveset or gadolinium-diethylenetriaminepentaacetic acid (Gd DTPA), once on the 13th and once on 14th day after inoculation. Animals were scanned on a GE 3T clinical system (Signa Excite, GE health) using a 50 mm (diameter) × 108 mm RF rung length small animal imaging coil (Litzcage small animal imaging system, Doty Scientific Inc.). A set of T1-pre, DCE T1-weighted, and T1 post images were acquired in each experiment. Multiple flip angle (2°, 5°, 10°, 15°, 20° and 25°) fast 3D spoiled gradient-echo (3D SPGRE) images were obtained, for a total scan time of 15 minutes. Gadofosveset was administered at 0.12 ml/kg (0.03 mmol/kg) and Gd DTPA was administered at 0.2 ml/kg (0.1 mmol/kg). A nested model selection (NMS) approach was used to estimate permeability parameters from DCE MR experiments. Resting (precontrast) T1 map was used to calculate the relaxivity change (ΔR1). Toft's extended model and its reduced forms were used to explain the behavior of contrast concentration of each voxel for estimating permeability parameters such as ve, vp, and Ktrans. F-Statistic was used to select the best model for

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

each voxel. All analyses were done using SRAIF and MSAIF. The MSAIFs were selected by an expert radiologist, and the SRAIF is the result of a previously reported study. Both AIFs were calibrated to blood relaxivity and normalized to white matter.

Results

There was high correlation between the Ktrans values calculated for each contrast agent, using the two AIF profiles (ICC = 0.95 and 0.94 for Gadofosveset and Gd DTPA respectively); however, the mean Ktrans was considerably different for the contrast agents due to their different molecular size. Even though the mean values of ve and vp using the same AIF are in strong agreement for both contrast agents, these values have a lower correlation between the two AIF profiles (for ve, ICC = 0.39 and 0.42 for Gadofosveset and GD DTPA respectively and for vp, ICC = 0.0077 and 0.56).

Conclusion

In this study, we assessed variations of calculated permeability parameters (ve, vp and Ktrans) when estimated using two different AIF profiles (MSAIF and SRAIF). For each contrast agent, the results show less variation in Ktrans, since it is directly related to the time trace of contrast concentration for both AIFs. However, ve and vp are more susceptible to the AIF profile change. These results show the importance, sensitivity and biasing level of each estimated permeability parameter against different AIF profiles.

Regional Cerebral Blood Flow in Depression: Arterial Spin Labeling Magnetic Resonance Study

Kaichi, Y.[1]·Higaki, T.[1]·Nakamura, Y.[1]·Honda, Y.[1]·Komoto, D.[1]·Date, S.[1]·Awai, K.[1]·Akiyama, Y.[2]·Okamoto, Y.[1]·Yamawaki, S.[1]
[1]Hiroshima University, Hiroshima, JAPAN, [2]Hiroshima University Hospital, Hiroshima, JAPAN.

Purpose

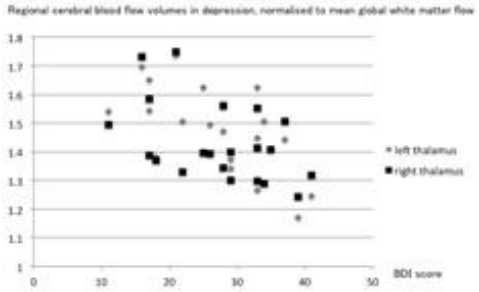
Findings in the limited number of studies that addressed changes in cerebral blood flow (CBF) in depressed individuals are inconsistent. We investigated changes in CBF using arterial spin labeling (ASL) MR imaging (MRI) in depressed and healthy persons.

Materials & Methods

Our study included 58 participants, 27 were healthy and 21 suffered from depression. They underwent imaging on a 3T MRI system between February and October 2012. Arterial spin labeling and echo-planar images were subtracted and averaged to yield perfusion-weighted images. Region-of-interest (ROI) analysis was applied to the bilateral hippocampi, thalami, caudate nuclei, lentiform nuclei, cortex, and white matter. To reduce potential interindividual variability in CBF we normalized all CBF ROI data by dividing each participant's ROI data by his/her global mean CBF value of the white matter. Group differences in CBF and their associations with clinical features were examined.

Results

Non-normalized CBF in all ROI except the bilateral thalami was significantly lower in depressed than healthy individuals. The bilateral thalamic normalized CBF was significantly higher in depressed than healthy individuals (left: p = 0.005, right: p = 0.008). There was a significant correlation between the bilateral thalamic normalized CBF and the Beck Depression Index scores in depressed patients (left: r = -0.62, right: r = -0.47).



Conclusion

In patients suffering from depression CBF in most parts of the brain was decreased. The effect of depression on the CBF of the bilateral thalami was minimal.

Comparison of Subcortical Volumes in Patients with Ischemic Stroke or Risk Factors for Stroke Using Manual Tracing Versus FreeSurfer Automated Segmentation

Krishnaraj, M.·Gupta, J.·Martens, N.·Kleefisch, C. J.·Nair, V. A.·Zeng, H.·Masodkar, K.·Abellaneda, A.·Jensen, M.·Chacon, M.·Sattin, J.·Prabhakaran, V.
University of Wisconsin
Madison, WI.

Purpose

Subcortical volume comparisons with manual versus automated segmentation methods have not been well studied. The objective of our study was to evaluate any differences between manual and FreeSurfer-automated segmentation for computing volumes of subcortical structures. Further, we compared volumes of subcortical structures between patients with ischemic stroke, patients with risk factors for stroke, and age-matched healthy controls.

Materials & Methods

Forty-one patients were scanned within seven days of onset of ischemic stroke (mean age = 61.1 years), 13 patients with stroke risk factors (mean age = 66.2 years) and 31 healthy controls (mean age = 56.6 years) were scanned on a GE 3T MRI scanner. Whole brain 3D T1-

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

weighted BRAVO FSPGR images were collected and volumes (cc) of eight subcortical structures (right and left putamen, caudate, pallidum, and thalamus) were generated with either expert manual tracing via MRIcroN or with FreeSurfer-Linux-centos4-stable-pub-version 5.1.0. A two-sample t-test was used for statistical comparison of computed volumes derived from manual tracing versus automated segmentation. Next, subcortical structure volumes computed by manual tracing between healthy controls, patients with ischemic stroke and patients with risk factors for stroke were analyzed with t-tests and compared. Finally, we utilized Dice's coefficient (DSC) as a statistical means to compare the volumes of overlap between the methods of segmentation. Values for DSC range from zero (indicating no spatial overlap) and one (signifying complete overlap). We utilized a DSC of greater than 0.700 as recommended by Zijdenbos et al (1994) to indicate a good overlap.

Results

There were no statistically significant differences (corrected $p<0.006$) between manual tracings and FreeSurfer for six out of eight subcortical structures in controls, five out of eight structures in patients with stroke risk factors, and four out of eight structures in patients with stroke. When comparing manually traced controls with patients with risk factors for stroke and ischemic stroke, only the right thalamus and right pallidum showed statistically significant differences in their computed volumes (corrected $p<0.006$). Dice's coefficient revealed good overlap in seven out of eight subcortical structures in controls, six out of eight structures in patients with stroke risk factors and only four out of eight structures for patients with stroke (DSC>0.700).

Conclusion

Our results suggest that there are increasing differences in volumes computed by expert manual tracing in comparison to automated FreeSurfer segmentation with increasing levels of vascular disease severity (stroke patients > patients with risk factors for stroke > normals). Overall significant differences were seen in the volumes of subcortical structures when comparing healthy subjects with patients with ischemic stroke or risk factors for stroke.

eP-56

Intravascular (Blood Pool) Contrast Agent and Dynamic Contrast-Enhanced T1 MR Imaging Using Nested Model Selection: Rat Brain Tumor Kinetics

Chwang, W. B.·Jain, R.·Nejad-Davarani, S.·Iskander, A.·Vanslooten, A.·Schultz, L.·Arbab, A.·Bagher-Ebadian, H.
Henry Ford Health System
Detroit, MI.

Purpose

The purpose of this study was to investigate parameters of vascular physiology -- plasma volume (vp), forward vascular transfer constant (Ktrans), and volume of the extravascular extracellular space (ve) in a rat glioma model using two different contrast agents, an intravascular (blood pool) agent (gadofosveset) and an extravascular agent (gadolinium-diethylenetriaminepentaacetic acid, Gd-DTPA). These parameters were estimated using dynamic contrast-enhanced (DCE) T1 nested model selection (NMS)1.

Materials & Methods

Dynamic contrast-enhanced T1 MRI studies were done in nine Fisher 344 rats inoculated intracerebrally with 9L gliosarcoma cells. Animals were scanned using both gadofosveset and Gd-DTPA, 24 hours apart. For DCE MRI, multi flip angle (2 to 35) fast SPGR 3D images were obtained to create T1 maps. Dynamic T1-weighted images were obtained for 15 minutes using a fixed 30-degree flip angle. vp, Ktrans, and ve were estimated using NMS from the DCE data1, using a standardized arterial input function. Descriptive statistics were computed for the two contrast agents, as well as for the whole lesion and the central core. Nonparametric Wilcoxon signed rank tests were done, and intra-class correlation coefficients (ICC) were computed to assess the agreement or reliability between the two contrast agents.

Results

For the whole lesion, Ktrans measures were significantly lower ($p = 0.0039$) using gadofosveset compared to Gd-DTPA, and there was almost perfect agreement between the two contrast agents. Both ve and vp, measurements were not statistically different, and there was almost perfect agreement for ve and substantial agreement for vp. For the central core, Ktrans was significantly lower ($p = 0.0039$) using gadofosveset compared to Gd-DTPA, with substantial agreement. No difference was observed between the contrast agents for ve and vp. Substantial agreement was observed for vp, but not for ve which showed poor agreement.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Table 1. Whole lesion analysis in 9 animals scanned with Gadofosveset as well as Gd-DTPA

	Contrast agent	Mean (SD)	p-value	ICC	Agreement
Ktrans (min-1)	Gadofosveset Gd-DTPA	0.025 (0.008)0.046 (0.011)	0.0039	0.848	Almost perfect
ve (%)	Gadofosveset Gd-DTPA	22.7 (4.7)23.6 (5.6)	0.425	0.880	Almost perfect
vp (% or ml/100 g)	Gadofosveset Gd-DTPA	1.5 (0.5)1.6 (0.4)	0.25	0.798	Substantial

Conclusion

Both ve and vp can be measured accurately whether we use an extravascular or intravascular contrast agent in an animal glioma model. Ktrans measurements were significantly lower using a blood pool contrast agent due to the much larger size of the albumin-bound contrast agent, and these were measured with very good accuracy using NMS in DCE MRI. The goal of this research is to demonstrate the stability of NMS in DCE MRI for measurement of these important vascular physiology markers which can provide important information about the tumor microenvironment, and hence, could potentially expand their role into prognostic or predictive imaging biomarkers, an area of very active clinical interest.

"Functional" MR Imaging Protocol for Treatment Decision, Presurgical Planning and Imaging-Guided Surgery of Brain Space-Occupying Lesions

Katsaros, V. K.[1,2]·Papanikolaou, N.[3]·Liouta, E.[2]·Hermoye, L.[4]·Stranjalis, G.[2]

[1]St. Savvas Anti-Cancer Oncology Hospital, Athens, GREECE, [2]University of Athens, School of Medicine, Evangelismos Hospital, Athens, GREECE, [3]STEP-C, Crete, GREECE, [4]Imagilys, Brussels, BELGIUM.

Purpose

To demonstrate our "functional" MRI protocol for treatment decision, presurgical planning, imaging-guided surgery and treatment monitoring of brain tumors and space-occupying lesions.

Materials & Methods

From September 2011 until today, 167 patients (212 examinations) with suspicion of brain tumor were evaluated presurgically, as well as postsurgically (45 patients). Our evaluation protocol included neuropsychologic tests, structural MRI (3D-T1 W, FLAIR, and T2 W), SWI, fMRI, diffusion and perfusion MRI, as well as spectroscopy on a 1.5T magnet before surgery and 3/12 months followup after surgery, radio and/or chemotherapy. The fMRI paradigms were selected according to the neuropsychologic results. The acquired and postprocessed data from structural, functional and DTI tractography sequences were used for differential diagnosis and treatment decision. If surgical approach was chosen (biopsy, ablative or gross total excision) data were transferred to the neuronavigation system and were used for presurgical planning and for "functional" imaging-guided surgery. In all operated cases the pathologic correlation was available.

Results

Thirty-two patients were excluded of the study either because they did not co-operate very well resulting in poor image quality, or because brain tumor was excluded. Our cohort (135 patients) comprised of 21 cases with low-grade gliomas, 44 high-grade gliomas, one DNET, five lymphomas, 31 meningiomas, two cavernomas, one DVM, 27 metastases (5 solitary), two colloid cysts and one postinfectious angiitis. Using a “validated algorithm” for intra-axial brain tumors we were able to establish the correct presurgical diagnosis in 132/135 patients (97.8%). In 77 patients the combination of neuropsychologic and neuroimaging evaluation emerged the need for surgery. The "functional" imaging-guided surgery in most of the tumors allowed gross total excision especially in the groups of low-grade gliomas and meningiomas.

"Validated algorithm" illustrates order of methods used to diagnose and differentiate intraaxial masses. Each method provides an answer to a specific question, which is used as a discriminator to distinguish lesions. 1.1/1000 mm^2 /ADC = $1.1x10^{-3}$ mm^2/sec ADC=apparent diffusion coefficient, CE=contrast material enhanced, Cho=choline, NAA=N-acetylaspartate, rCBV=relative cerebral blood volume, TDL=tumefactive demyelinating lesion.

Radiology 2007; 243:539-550

Conclusion

"Functional" MRI approach in combination with neuropsychologic evaluation is an invaluable tool for differential diagnosis, treatment decision, planning and guiding the surgery, as well as for treatment monitoring, thus providing the best health-care management of patients with brain space-occupying lesions.

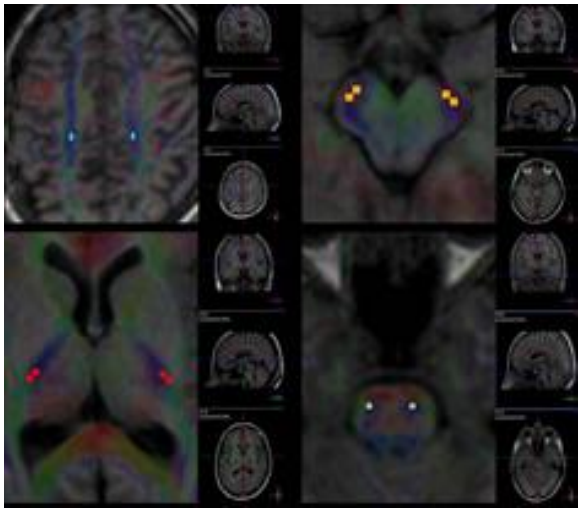
Transcranial Magnetic Stimulation and Magnetic Resonance with Diffusion Tensor Imaging in Amyotrophic Lateral Sclerosis Patients: Combination and Correlations of their Measurements

Stecco, A.·Nasuelli, N.·Mazzini, L.·Cantello, R.·Perchinunno, M.·Carriero, A.
ASU Maggiore della Carità
Novara, ITALY.

Purpose
To determine the diagnostic accuracy of MRI with DTI and TMS with MEPs in UMN assessment in ALS patients; secondary goal to assess if there is a correlations between DTI metric and MEPs.
Materials & Methods
Seventeen patients (10 males and seven females; age range 25-74 years, mean 47) affected by ALS, underwent a TMS and MRI DTI evaluation within 30 days, during their follow-up evaluation. Nine of them had a clinical presentation at upper limbs, five at lower limbs, four as a bulbar type. Twelve were classified (El Escorial) as definite ALS, three probable ALS and two possible, with a ALS-FRS range of 17-40, mean of 33. By TMS, cortical motor threshold (MT) at rest, central motor conduction time (CMCT), cortical MEPs and spinal MEPs have been recorded. MR imaging DTI acquisitions have been performed with a 64 directions oriented tensor, on a 1.5T magnet, without ECG/PPU trigger. The DTI has been acquired on the brain with a 8-channels Head Sense Coil. Diffusion tensor imaging postprocessing has been conducted on a dedicate workstation loaded with proprietary DTI and FiberTracking software, and a two-observer (in consensus), voxel-by-voxel single-point ROI-based analysis on the following several anatomical levels: semioval centers (SC), internal capsule - posterior limb (IC), cerebral pedicle (PED), pons (PON). The color-coded FA map and a 3DT1-weighted axial image served as reference for ROI positioning assistance. Fractional anisotropy and ADC values have been recorded and compared to an institutional healthy volunteers database already existing. Statistical analysis has been carried out by mean of Wilcoxon-Mann-Whitney test and Cochrane Q test, together with sensitivity assessment. SAS v.8.2 and Excel 2007 have been adopted.
Results
Only the internal capsule level FA measurements (mean FA = 0.64) differed statistically from the mean and range (0.74; 0.67-0.81) of values from the control data. Sensitivity assessment of MEPs (with or without a clinical sign) and DTI, showed a slight superiority of DTI if compared to MEPs alone, but when MEPs are combined with the clinical sign show a better sensitivity. The same behavior and results showed for TCMC.



Conclusion
MEPs TCMC and DTI with FA measurement at the internal capsule level, appear to study with the same sensitivity the quality of cortico-spinal tract in ALS patients in evaluating UMN. The clinical signs, if present, add sensitivity to TMS evaluation.

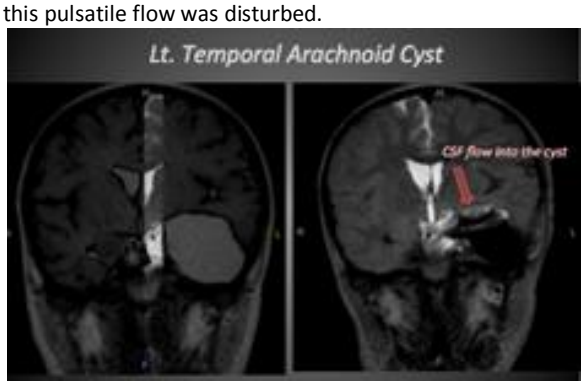
Visualization of Cerebrospinal Fluid Dynamics in Physiologic and Pathophysiologic Condition Using MR Imaging Arterial Spin Labeling Technique

Yamada, S.[1]·Miyazaki, M.[2]·McComb, G. J.[3]
[1]Tokai University Oiso Hospital, Oiso Naka-gun Kanagawa, JAPAN, [2]Toshiba Medical Research Institute USA, Vernon Hills, IL, [3]Childrens Hospital of Los Angeles, Los Angeles, CA.

Purpose
Cerebrospinal fluid (CSF) flow has been studied using cardiac-gated phase contrast MRI for a decade. This technique, however, allows depiction of "to-and-fro" motion only within one cardiac cycle. We have developed a time spatial labeling inversion pulse (time-SLIP) technique that permits CSF flow observation over a 1-6 sec period. Using this method we have investigated the hydrodynamics of CSF flow in normal volunteers and its alterations in pathophysiologic conditions.
Materials & Methods
The time-SLIP technique was used on healthy volunteers and patients with CSF-related disorders using a 1.5T and 3T MRI scanner. Using a scan time of 3-6 min, time-SLIP was applied to the region of the aqueduct of Sylvius, foramen of Monro and prepontine cisterns.
Results
Active exchange of CSF between the lateral and third ventricles and between the third and fourth ventricles was observed in all normal volunteers. These CSF exchanges

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

were absent in the presence of hydrocephalus. Aqueductal CSF flow was nonexistent in the presence of aqueductal occlusion. Exaggerated turbulent CSF flow was observed at the aqueduct with both hydrocephalus except in the presence of aqueductal occlusion. Cerebrospinal fluid flow between the cyst and basal cistern were observed after the surgical internal fenestration for temporal arachnoid cyst. Large pulsatile CSF movement could be observed at the subarachnoid space at the cranio-cervical junction in normal volunteers. In patients with hydorsyringomyelia this pulsatile flow was disturbed.



Conclusion
Using a MRI time-SLIP technique, CSF movements in normal and altered conditions are observable and will add to our understanding of normal and pathophysiologic situations.

MR Findings in Patients with Nocardia Brain Abscess

Kubal, W. S.·Shastri, R.
University of Arizona
Tucson, AZ.

Purpose
Nocardia brain abscesses are relatively uncommon comprising approximately 2% of all brain abscesses. Retrospective literature review found only 120 cases reported between 1950 and 1993. The more current literature consists of small series and case reports often with few if any descriptions of MR findings. Unfortunately, nocardial infection carries a high mortality rate reaching 34% and is considered the most lethal of all brain abscesses caused by microorganisms. The purpose of this report is to illustrate the MR findings of this uncommon but highly lethal intracranial infection.
Materials & Methods
Retrospective review yielded eight patients with nocardial brain abscess. This study was HIPAA compliant and approved by the local IRB. Each patient had at least one MR obtained on a high field unit. Each patient had histologically proven nocardial infection.
Results
The eight patients ranged in age from 19 to 74 years. Six were male and two were female. Three were transplant patients and two had a pre-existing malignancy. In all patients lesions were either multicentric and/or a conglomerate multilobular mass. All lesions were characterized by peripheral enhancement and surrounding vasogenic edema. Larger lesions showed central nonenhancement, rim that was dark on T2 sequences and central restricted diffusion. One patient demonstrated leptomeningeal enhancement that extended to involve the spinal cord. Gradient-echo imaging was performed as part of each exam; no hemorrhage was seen. Diffusion tensor imaging was performed in one patient and showed infiltration and attenuation of white matter tracts.
Conclusion
Nocardia brain abscesses have imaging findings of a typical pyogenic infection. Given their propensity to occur in immune suppressed patients or in patients with pre-existing malignancy, the restricted diffusion is particularly useful in distinguishing them from intracranial neoplasm. The radiologist should be aware that the lesions often are multicentric and that leptomeningeal spread of disease may occur.

Evaluation of Dawson's Fingers in Neuromyelitis Optica Spectrum Disorders and Multiple Sclerosis: A Case-Control Study

Raz, E.[1]·Saba, L.[2]·Kister, I.[1]·Fatterpekar, G.[1]·Herbert, J.[1]·Omari, M.[1]·Lui, Y. W.[1]·Loh, J.[1]
[1]New York University, New York, NY, [2]University of Cagliari, Cagliari, ITALY.

Purpose
There are no studies that examine differences in the periventricular lesional pattern or the frequency of Dawson's fingers in MS and neuromyelitis optica spectrum disorders (NMOsd). To compare the periventricular lesional pattern and the presence of Dawson's fingers in MS and NMOsd.
Materials & Methods
MR imaging of 20 NMO and 40 matched MS patients were evaluated. Two neuroradiologists evaluated the periventricular lesions on FLAIR images (A = no lesions; B = smooth periventricular linear hyperintensity, focal or diffuse; C = discrete periventricular lesions with or without smooth periventricular linear hyperintensity; D = diffuse irregular confluent hyperintensity) and the presence of Dawson's fingers. Group comparisons and inter-reader agreement statistics were performed.
Results
Periventricular patterns: Reader 1, A-B: NMOsd = 17/20; MS = 2/40; C-D: NMOsd = 3/20; MS = 38/40; Reader 2, A-B: NMOsd = 16/20; MS = 2/40; C-D: NMOsd = 4/20; MS =

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

38/40. Presence of Dawson's fingers: Reader 1 = 0/20 NMOsd; 37/40 MS. Reader 2 = 1/20 NMOsd; 31/40 MS. A significant difference between the two groups of patients ($p<0.001$) was found. Inter-reader agreement for periventricular pattern description and detection of Dawson's fingers was respectively good (k = 0.604) and very good (k = 0.763).
Conclusion
Certain periventricular lesional patterns are more common in NMO than MS. Dawson's fingers are more common in MS. Evaluation of sagittal FLAIR can help in the differential diagnosis between these two entities.

Brain Medullary Veins Visibility with Susceptibility-Weighted MR Imaging in Clinically Isolated Syndromes and Relapsing-Remitting Multiple Sclerosis

Rovira, A.·Aymerich, F. X.·Auger, C.·Huerga, E.·Mitjana, R.·Tintore, M.·Alonso, J.·Montalban, X.
Hospital Vall d'Hebron
Barcelona, SPAIN.

Purpose
Susceptibility-weighted imaging (SWI) is a novel MR technique that allows visualizing veins in the brain due to an inverse BOLD effect. Previous studies have described that relapsing-remitting multiple sclerosis (RRMS) patients show in SWI images a significantly reduced visibility of periventricular white matter veins compared to healthy controls (HC), with a negative correlation with T2 lesion load. In this work we propose to extend these studies to patients presenting with clinically isolated syndrome (CIS), who represent the earliest stage of possible multiple sclerosis (MS).
Materials & Methods
One hundred one subjects (17 HC; 48 CIS; 36 RRMS) were examined with 3T MRI (T2 and SWI). Susceptibility-weighted images were acquired using a 3 mm-slice thickness transverse GE sequence (TR/TE = 32 ms/24.6 ms). A home-developed algorithm was used to detect vein pixels in eight rectangular supraventricular white matter ROIs.
Results
Twenty-eight (58%) CIS patients had subclinical brain lesions (pCIS), whereas 20 (42%) had not (nPCIS). There were significant differences in the number of vein pixels among HC, RRMS and CIS groups ($p = 0.047$). Dunnett's test only showed significant difference comparing RRMS versus HC ($p = 0.033$). However, pCIS showed a significant lower number of vein pixels than nPCIS ($p = 0.028$). No significant correlation was observed between T2 lesion load and number of veins pixels.
Conclusion
Clinically isolated syndrome and RRMS patients showed in supraventricular white matter regions a decrease in the number of vein pixels, which is associated with the presence, but not with the volume, of T2 lesions. This finding likely reflects an increase BOLD effect (decrease in deoxihemoglobin) and supports the concept of a widespread hypometabolic process in MS.

KEYWORDS: Multiple sclerosis, Susceptibility-weighted imaging

eP-63

Progressive Multifocal Leukoencephalopathy in HIV and non-HIV Hosts with Prominent Inflammatory Changes

Lin, D.·Zessler, A.
Johns Hopkins University
Baltimore, MD.

Purpose
Progressive multifocal leukoencephalopathy (PML) is a rare and frequently fatal demyelinating disease caused by the JC polyomavirus. It predominantly affects patients in immunosuppressed states, and therefore is associated with a wide range of diseases including HIV, transplant recipients, monoclonal antibody therapy, and diverse rheumatic, oncological, and hematologic diseases. The purpose of this study is to review the MRI findings in patients with PML in a HIV and non-HIV setting, as well as to correlate with clinical course and final diagnosis.
Materials & Methods
Ten patients with acute neurologic symptoms, including four patients with HIV and clinical question of immune reconstitution inflammatory syndrome (IRIS), and six patients without HIV, underwent clinical MRI. Among the six non-HIV patients, two had SLE, two had lymphoma (one cutaneous T-cell and one follicular), one had Wegener's granulomatosis, and one had renal transplant. All patients were confirmed to have PML either by CSF analysis with PCR, or brain biopsy. The imaging findings were re-analyzed retrospectively and compared to the clinical radiology reports and clinical findings.
Results
While most of the cases show mass-like FLAIR hyperintense lesions with little or no mass effect similar to the classic findings of PML, there are features indicating a less typical component of active inflammation or demyelination in this cohort. Fifty percent (two in HIV and three in non-HIV) of the 10 patients showed gadolinium contrast enhancement of the PML lesion, and 50% (three in HIV and two in non-HIV) show restricted diffusion predominantly along the rim of the lesion. At least in two cases mild DWI hyperintensity was evident but accompanied by ADC hyperintensity suggestive of facilitated diffusion. In two cases there were cortical gray matter in addition to white matter involvement, and in three cases the deep gray matter also was involved. Extensive vasogenic edema with moderate mass effect was evident in two patients (one HIV). In one HIV patient with PML-IRIS, 1H-MRS revealed prominently elevated

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Cho/Cr and Cho/NAA ratios with a presence of lactate consistent with inflammation or demyelination. In the same patient brain biopsy was performed, with histopathology revealing more inflammation, lymphoplasmacytic, than in the classic case of PML. Because of the less typical neuroimaging findings, the initial radiology report suggested the diagnosis of subacute infarcts in two of 10 cases, and provided CNS lymphoma as a differential diagnosis in three cases as well as infiltrating astrocytoma or other CNS infection in two cases.
Conclusion
Prominent inflammation occurring in PML, often in the setting of IRIS with HAART therapy in HIV hosts as well as non-HIV patients, can have unusual neuroimaging findings including contrast enhancement, cytotoxic edema, mass effect, and gray matter involvement. It is particularly important to recognize these findings and to suggest the diagnosis given appropriate clinical findings.

eP-64

Neuropsychiatric Systemic Lupus Erythematosus: Prediction of Subsequent Development of Brain Lesions with MR Imaging

Futatsuya, K.[1]·Kakeda, S.[1]·Kaichi, Y.[2]·Moriya, J.[1]·Ohnari, N.[1]·Saito, K.[1]·Tanaka, Y.[1]·Korogi, Y.[1]
[1]University of Occupational and Environmental Health, Yahatanishi-ku, Kitakyushu, JAPAN, [2]Hiroshima University, Hiroshima, JAPAN.

Purpose
Systemic lupus erythematosus (SLE) is an autoimmune disease that is frequently manifested by involvement in the central nervous system, and the antiphospholipid syndrome (APS) may affect the incidence and pathogenesis of cerebrovascular diseases in the SLE patients. Cerebral infarctions, cortical atrophy, and multifocal gray matter and/or white matter lesions frequently are observed at MR imaging in patients with SLE, and the subsequent development of these lesions is seen in some patients. In this study, we assessed whether the clinical or initial MRI findings help predict the subsequent development of the brain lesions in SLE patients.
Materials & Methods
Of the 256 SLE patients that underwent MRI, we identified 91 patients with follow-up MRI. From them, we enrolled 64 patients less than 50 years old to avoid the effect of age-related cerebrovascular diseases. By two radiologists, the initial MRI findings were reviewed and categorized as follows; large territorial infarctions, lacunar infarctions, localized cortical infarctions, watershed infarctions,micro-embolisms, basal ganglia lesions, callosal lesions, white matter hyper intensities, and hemorrhages on T2-weighted and/or FLAIR images. Similarly,we also classified the follow-up MRI findings. Based on the MRI findings, the 64 patients were divided into the following three groups; group A, the patients had no lesion at both initial and follow-up MRI; group B, the patients had the lesions at initial MRI, but no new lesions at follow-up MRI; group C, the patients had the lesions at initial MRI and a new lesion at follow-up MRI.
Results
The numbers of the patients in each group were 18 for groupA, 32 for group B, and 14 for group C. In follow-up MRI, we found the 19 new lesions in group C; large territorial infarction (n = 1), lacunar infarctions (3), localized cortical infarctions (4), watershed infarctions (2), micro-embolism (1), basal ganglia lesions (2), and white matter hyper intensities (6). The prevalence of the patients with APS was more common in the group C (10/14: 71%) than in the group A (3/18: 17%) and group B (7/32:22%). At initial MRI, localized cortical infarction (50% versus 9%, $p < 0.001$) and lacunar infarction (50% versus 0%, $p < 0.05$) were significantly more common in group C than in group B. For the prevalence of the other findings at initial MRI, there were no statistically significant differences between the groups.
Conclusion
In SLE patients, the presence of APS as well as localized cortical infarction and lacunar infarction at the initial MRI may be predictors for the subsequent development of brain lesions.

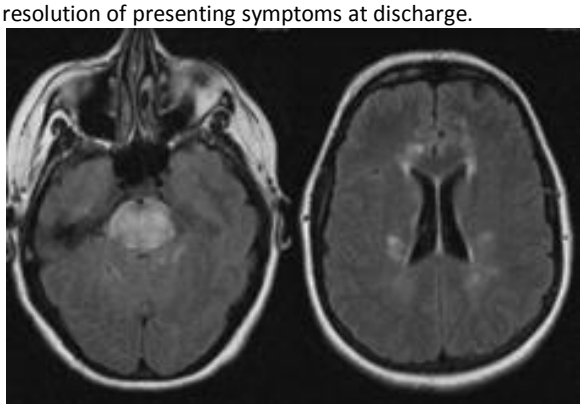
Posterior Reversible Encephalopathy Syndrome and the Brainstem: Features of Infratentorial-Predominant Posterior Reversible Encephalopathy Syndrome

Fitzgerald, R. T.·Samant, R. S.·Burgin, K.·Kumar, M.·Ramakrishnaiah, R. H.·Van Hemert, R.·Angtuaco, E. J.
University of Arkansas for Medical Sciences
Little Rock, AR.

Purpose
Posterior reversible encephalopathy syndrome (PRES) is a clinico-radiologic neurotoxic process that typically occurs in a setting of immune dysregulation accompanied by hypertension. Typical distribution of signal abnormality on MR involves the subcortical white matter of the parieto-occipital and posterior frontal regions. Atypical patterns of PRES involvement, including those involving the infratentorial brain, are well known; however, changes in these regions often are superimposed upon the more typical sites of involvement. We describe six cases that manifested with predominant involvement of the brainstem and cerebellum and lacked the classic pattern of supratentorial involvement, thus potentially obscuring a diagnosis of PRES from the unwary radiologist.
Materials & Methods
An institutional database of PRES patients was created

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

through an IRB-approved search of the electronic record from 2007-2012. MR images were reviewed and classified by two neuroradiologists. Clinical data were collected through review of existing electronic medical records.
Results
Six cases among a database of 85 PRES patients treated at our institution between 2007 and 2012 displayed an atypical distribution of FLAIR/T2 signal abnormality predominantly involving the brainstem and/or cerebellum. In these patients, signal abnormalities within the supratentorial brain, when present, showed a predominantly periventricular distribution rather than the classically described and more commonly encountered peripheral, subcortical distribution. In three cases, the pattern of periventricular involvement was reminiscent of a demyelinating process. Four of six patients presented with severe hypertension. Additional predisposing factors included systemic lupus erythematosus (1) and sepsis (2). Presenting symptoms included altered mental status (4), visual disturbance (2), headache (2), and seizure (2). Five of six patients presented with renal dysfunction. One patient died and the remainder showed complete resolution of presenting symptoms at discharge.



Conclusion
In contrast to the typical pattern of FLAIR signal abnormality in PRES, patients with brainstem/cerebellar-predominant PRES may manifest supratentorial changes in a periventricular distribution that, in some cases, mimics the appearance of a demyelinating process. Predisposing clinical factors in this cohort were similar to those encountered in the PRES population as a whole.

Delayed Neuroimaging Findings of Gadolinium Imaging of Brain Disease Using Gadobenate Dimeglumine: A Higher Relaxivity Contrast Agent

Boyko, O. B.·Shiroishi, M.·Lerner, A.·Kim, P. E.·Zee, C.·LAW, M.
University of Southern California
Los Angeles, CA.

Purpose
To demonstrate the clinical imaging findings of delayed T1 and/or FLAIR imaging at 1.5T using a higher relaxivity contrast agent (HRCA) gadolinium contrast agent gadobenate dimeglumine (MultiHance®).
Materials & Methods
Twenty-five patients who had delayed imaging after completion of routine postgadolinium sequences were reviewed. Delayed imaging was do either to repeat T1 and/or FLAIR localized images for MR spectroscopy acquisition or other clinical reasons for the patient to be brought back to the MRI suite. Delayed time ranged from 12 minutes to 26 hours.
Results
As expected 22 cases where imaging was acquired within one hour of contrast administration demonstrated continued enhancement of lesions. Unexpectedly two lesions imaged 12 hours postcontrast administration (abscess and glioma) demonstrated delayed gadolinium enhancement and persisting enhancement.
Conclusion
Higher relaxivity contrast agents are now available for neuroimaging and a possible clinical neuroimaging pitfall of delayed/continued enhancement can occur which is not to be mistaken for blood products and hemorrhage.

KEYWORDS: Contrast enhancement, Contrast, Higher Relaxivity Gadolinium Contrast

Peritumoral Edema and Apparent Diffusion Coefficient Characteristics of Angiomatous and Microcystic Meningiomas Are Distinct from Other Low-Grade Meningiomas as well as Atypical and Anaplastic Meningiomas

Azizyan, A.·Eboli, P.·Drazin, D.·Maya, M.·Bannykh, S.
Cedars Sinai Medical Center
Los Angeles, CA.

Purpose
To determine whether meningiomas of angiomatous or microcystic histology have MRI features which are unique from other types of low-grade meningiomas and from meningiomas of high-grade. In particular, we tested whether ADC values can reliably separate biologically aggressive and low-grade meningiomas in the preoperative setting.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Materials & Methods
Preoperative MRIs of 71 patients with meningiomas were reviewed. Based on histologic characteristics, the tumors were categorized into three groups. Group 1 contained 12 pure microcystic, three pure angiomatoid and seven mixed, angiomatoid and microcystic tumors. Group 2 included WHO grade II and WHO grade III tumors, 28 of which were classified as atypical and nine as anaplastic. Group 3 included WHO grade I meningiomas without angiomatoid or microcystic features. Two reviewers determined maximum tumoral apparent diffusion coefficient (ADC) and cerebral blood volume (CBV) by placing a standardized region of interest within each meningioma. Apparent diffusion coefficient values were normalized to values in the lateral ventricles. Peritumoral edema index was measured as the volume of edema plus tumor divided by tumor volume.

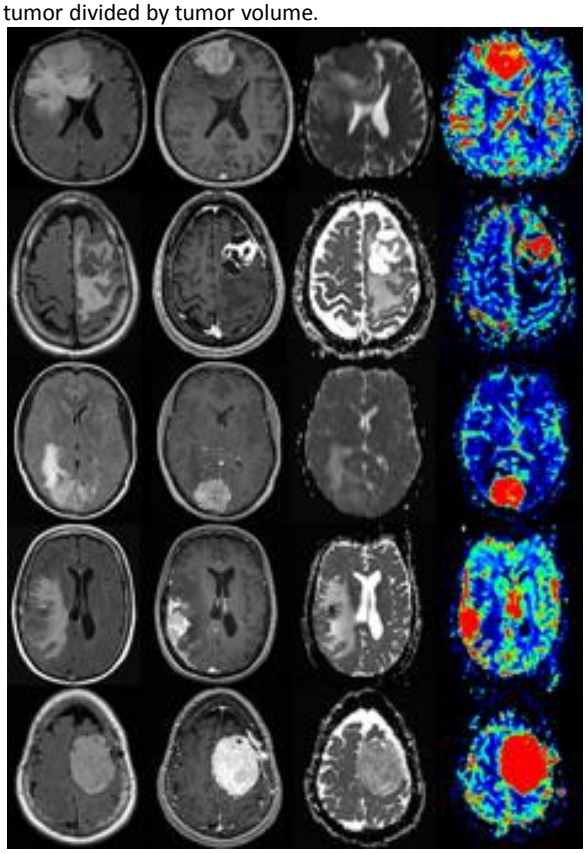

Figure: Group 1 (rows 1 and 2), Group 2 (rows 3 and 4) and Group 3 (row 5).

Results
Group 1 and group 2 meningiomas had significantly higher edema volume indices when compared to the group 3 tumors ($p = 0.003$ between group 1 and 3, $p<0.0001$ between group 2 and 3). There was no significant difference in edema index between group 1 and 2. The ADC values in the biologically aggressive group 2 were significantly higher than either of the two benign groups (1and 3), with p values of 0.0007 and 0.001 respectively. There was no statistically significant difference in the tumoral CBV values between the three groups.

Conclusion
WHO grade I meningiomas of angiomatoid and microcystic histology demonstrate a significantly higher edema index when compared to the rest of the WHO grade I meningiomas studied. Furthermore, the edema index of angiomatoid and microcystic meningiomas fails to distinguish them from the biologically aggressive WHO II and WHO III tumors of group 2. Internal ADC values can reliably distinguish the aggressive group of meningiomas from both groups of low-grade meningiomas.

eP-68

MR Imaging Diffusion Characteristics in Glioblastoma with Primitive Neuroectodermal Tumor-Like Components: An Uncommon Tumor Subtype

Ali, S.·Joseph, N. M.·Perry, A.·Cha, S.
University of California San Francisco
San Francisco, CA.

Purpose
Glioblastoma multiforme (GBM) with primitive neuroectodermal tumor (PNET) components is an uncommon variant of GBM with pathology demonstrating sharply demarcated hypercellular nodules with primitive-appearing cells with high nuclear-to-cytoplasmic ratios, markedly hyperchromatic nuclei, and high mitotic rates in a background of infiltrating glial neoplasm. Recent studies describe PNET-like clinical behavior in these patients--with significantly increased propensity for CSF dissemination compared to conventional GBMs and a benefit of "PNET-like" platinum-based chemotherapy upfront or after having failed conventional GBM-type treatment (radiation and temozolomide). Few reports in the literature have described areas of reduced diffusion on MRI of patients with GBM-PNET, and given areas of hypercellularity in the PNET components on pathology, it is not surprising reduced diffusion would be seen on MRI. No study however has quantified the ADC values of these patients and compared them with diffusion characteristics of conventional GBMs. The purpose of this presentation is to quantitatively evaluate the DWI characteristics of GBM with PNET features and compare with published ADC values of conventional GBMs.

Materials & Methods
Eight patients with brain biopsy specimens yielding GBM with PNET features were referred to UCSF Pathology service for consultation. MR images of these patients were reviewed retrospectively. Diffusion-weighted imaging sequences were analyzed with multiple regions of interests placed within nonhemorrhagic areas of the tumor, and ADC values were measured. Results were compared to published data of ADC in pathology-proven conventional GBM cases from our institution.

Results

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Reduced ADC was seen in patients with GBM with PNET components with a mean 691 x 10^-6 mm2/sec (range 345 to 963) compared to previously published means of 1140 and 1610 x 10^-6 mm2/sec in the enhancing and nonenhancing components of conventional GBMs, respectively.

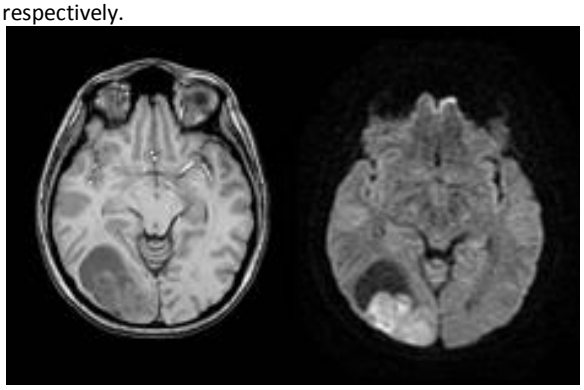

Figure: Axial diffusion-weighted (b1000) and post-gadolinium T1-weighted images demonstrating enhancing right occipital mass with significantly reduced diffusion in the solid component of the tumor. Apparent diffusion coefficient map not shown. Biopsy revealed GBM with PNET components.

Conclusion

We report significantly reduced ADC values in patients with GBM with PNET components compared to conventional GBMs. If demonstrated in a larger sample, when areas of reduced diffusion are seen on MRI in a high-grade glioma, a thorough histologic examination for presence of PNET components can be advocated, as patients with GBM-PNET may have a higher chance of developing CSF dissemination and may benefit for PNET-like chemotherapy.

KEYWORDS: GBM, Diffusion-weighted imaging, PNET

eP-69

MR Spectroscopy Detects Tumor Recurrence in Patients Treated with Bevacizumab

Hesselink, J. R.·Barkovich, M.·Almutairi, A.·Farid, N.·Kesari, S.
University of California San Diego Medial Center
San Diego, CA.

Purpose

To compare MR spectroscopy (MRS) with MR imaging and perfusion for detecting tumor recurrence in patients treated with bevacizumab.

Materials & Methods

Imaging studies and medical records of 39 patients undergoing treatment for brain tumors were reviewed. Seven patients who were being treated with bevacizumab and followed with MR imaging, MRS, and MR perfusion were included in the study. The three MR methods were evaluated independently for evidence of tumor recurrence. Brain tumors included five glioblastomas (GBM), one grade II gemistocytic astrocytoma, and one anaplastic oligodendroglioma on initial biopsy that was upgraded to a GBM after subtotal surgical resection.

Results

Elevated choline was observed in six patients, adjacent to the original tumor site in five and in the opposite hemisphere in one patient. The duration of bevacizumab therapy before MRS ranged from one to 18 months. Tumor recurrence was confirmed by biopsy in two patients, autopsy of one patient, and by clinical disease progression in the other three patients. The cerebral blood volume was minimally increased in only one patient. Increased T2 signal and gadolinium enhancement was noted in three patients, but they had been off bevacizumab for two and three months, respectively. The one patient with no choline elevation was clinically diagnosed with severe radiation necrosis.

Conclusion

In patients treated with bevacizumab, MRS was superior to MR imaging and perfusion for detecting tumor recurrence. Unlike T2 edema, contrast enhancement, and perfusion, the metabolic measures of MRS are not affected by bevacizumab.

KEYWORDS: Neoplasm recurrence, diagnosis, 1H MRS

eP-70

Assessment of Vascular Density in Glial Tumors Using Time-of-Flight MR Angiography at 7T: Initial Experience

Atchie, B.·Pinho, M.·Jiang, F.·Malloy, C.·Maher, E.·King, K.
University of Texas Southwestern Medical Center
Dallas, TX.

Purpose

Tumor vasoproliferation is a central part of tumor grading and with the advent of ultrahigh field strength MRI, novel approaches in the assessment of tumoral vascularity currently are under investigation. It has been shown that vascularity detected by ultrahigh field MRI correlates with post-mortem pathology in glioblastomas, but the prognostic value and potential treatment implications related to vascularity detected by these noninvasive means remains unknown. Because noninvasive monitoring of gliomas is a significant clinical problem, the possibility that vascular characteristics could serve as a biomarker is worth investigation. We aim to add to this body of knowledge by providing our experience with a unique technique in assesing the vascular density in glial tumors at 7T.

Materials & Methods

The study was institutional review board approved and HIPAA compliant. Nineteen subjects with biopsy proven glial neoplasms were evaluated on a 7T Philips Achieva scanner. Four patients were excluded from the sample for confounding factors related to large amounts of hemorrhage or necrosis (three patients) or prior surgery

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

(one patient). The remaining 15 subjects were evaluated per the following protocol; 3D TOF MRA and FLAIR sequences were performed on each patient and evaluated by three independent blinded radiologists. If the tumor was felt to demonstrate abnormal tumoral vascularity a 1.0 cm^2 ROI was chosen by the reviewer and placed over what was subjectively felt to represent the most vascular portion of the tumor. The numbers of abnormal vessels then were tallied according to a predetermined criterion and recorded along with the location of the ROI. Calculated vascular density then was correlated to the grade of the tumor.

Results

There was interobserver consistency when it came to determining the most vascular portion of a given tumor, with 18 of 23 ROIs placed within <1 cm of one another. For tumors determined to have definitely abnormal vasculature the mean vessel density was 12.7 vessels/cm^2 for grade IV, 5.6 vessels/cm^2 for grade III, and 4.8 vessels/cm^2 for grade I-II tumors. Although a trend towards greater vascular density was noted for higher grade neoplasms, groupwise correlations did not hold statistical significance due to the fact that half of the grade IV tumors failed to demonstrate any abnormal vascularity at all.

Conclusion

7T MRA depicts finely detailed images of tumor vascularity in primary brain tumors when present. Although high vascular density was a very specific finding for grade IV tumors, our correlations with grade did not reach significance due to a striking dichotomy in the observable vascularity of glioblastomas, with half of these tumors being avascular at MRA. These surprising findings warrant future investigation and may have implications in defining subsets of patients with different tumor genetics, response to therapy, and ultimately survival rates.

Histopathologic Evaluation of High-Grade Brain Tumors Infiltration Using High-Order Diffusion Tensor Imaging

Stefani, T.·Pereira, B.·Coste, A.·Khalil, T.·Chabert, E.·Kemeny, J. L.·Boyer, L.·Jean, B.
University Hospital Clermont-Ferrand
Clermont-Ferrand, FRANCE.

Purpose

Delineation of high-grade brain tumor is critical for treatment planning and prognosis but remains challenging using conventional MRI sequences. The aim of this study was to evaluate the peripheral white matter infiltration of high-grade brain tumors using high-order diffusion tensor imaging.

Materials & Methods

Local IRB approval and informed consent from patients were obtained. Seven patients were prospectively included and underwent 3T clinical MRI scans. MR imaging protocol included T2-WI, FLAIR, T2GRE, 3D gradient-echo sequences before and after contrast media injection and an EPI diffusion tensor sequence with 60 directions of gradient sampling (b = 3000). Patients then underwent surgical stereotactic tumor biopsy targeted with Leksell frame, according to standard procedure. An extra biopsy was performed in normal-appearing white matter adjacent to the tumor along the biopsy pathway. Histopathologic analysis of the biopsy was done using immunologic markers such as MAP2, Ki67 in order to estimate the percentage of tumor infiltration. Analysis of DT MRI datasets was done using in-house software for high order tensor resolution and generalized anisotropy (GA), generalized variance (GV), mean diffusion (MD) estimation at the exact coordinates of the biopsy sites. Finally a statistical analysis (Spearman correlation) was used to correlate GA, GV, MD and the infiltration percentage.

Results

There were significant correlation between the GA ($r = -0.956$ $p<0.05$) and GV ($r = -0.956$ $p<0.05$) values of tumor adjacent normal-appearing white matter and tumor infiltration percentage. Mean diffusion showed no significant correlation ($r = 0.598$ $p>0.1$) with infiltration percentage.

Conclusion

Our results show that GA and GV measurements derived from high-order diffusion tensor estimation are well correlated to tumor infiltration. Therefore the identification of high-grade brain tumor borders may be more accurate using high-order diffusion tensor imaging.

Can T1-Weighted Gradient Echo MR Scans Differentiate between Intra and Extracellular Ferumoxytol Enhancement?

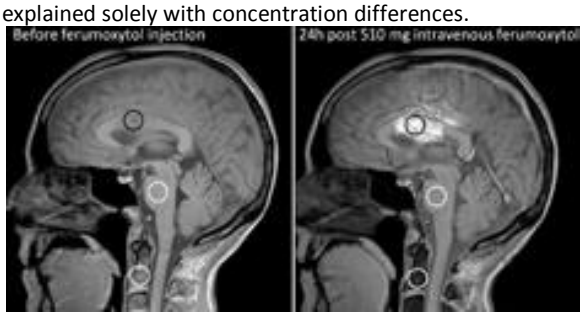
Varallyay, C. G.[1]·Muldoon, L. L.[1]·Neuwelt, E. A.[1,2]
[1]Oregon Health & Science University, Portland, OR,
[2]Department of Veterans Affairs Medical Center, Portland, OR.

Purpose

Ferumoxytol, a long circulating iron oxide nanoparticle has been approved by the Food and Drug Administration for iron replacement in patients with kidney failure. Due to its T1 and T2 relaxation time shortening effects it can be used (off label) as an MRI contrast agent. Early after injection it acts as a blood pool agent, and shows peak contrast enhancement 24 hours after administration. Ferumoxytol is eliminated from the plasma through the reticulo-endothelial system, by uptake of mononuclear cells mainly in the liver, spleen and bone marrow. The internalized ferumoxytol particles, clustered in lysosomes, exhibit a

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

substantially increased transverse relaxivity causing signal loss in gradient echo T1-weighted images. This differs from the hyperintense enhancement of extracellular particles. The purpose of this study was to analyze the potentials of ferumoxytol in assessing extra and intracellular contrast agent accumulation.
Materials & Methods
T1-weighted sagittal gradient echo brain MRIs were reviewed before and 24 hours after intravenous ferumoxytol injection in 39 patients with brain neoplasms. The administered doses were 2 mg/kg, 4 mg/kg or 510 mg ferumoxytol (13 patients in each dose group). Signal changes were analyzed in regions of interests in the second cervical vertebral body, in enhancing brain lesions and in the pons for reference.
Results
There was a dose-dependent signal decrease in the bone marrow in the spine 24 hours postferumoxytol injection, whereas increased signal was found in the CNS lesions. Figure 1 shows images of a representative case, a patient with glioblastoma. There is an avid signal increase in the region of the tumor 24 hours post-injection, combined with marked signal decrease of the bone marrow in the vertebral bodies of C2 and C3. This signal decrease most likely represents intracellular contrast agent. This patient already had received the same dose of ferumoxytol three months earlier with some residual signal loss in the vertebral bodies seen on the left image (the baseline image from three months before is not shown). The signal decrease in areas of low concentration residual iron oxide in the vertebral bodies suggests that signal changes caused by ferumoxytol (hyper versus hypointense) cannot be explained solely with concentration differences.



Conclusion
Using the clinically applicable dose up to 510 mg ferumoxytol and T1-weighted gradient echo sequences may help differentiate between mainly intracellular versus mainly interstitial contrast enhancement.

KEYWORDS: Contrast enhancement, Brain neoplasms, Ferumoxytol

"Soap Bubble" Pattern Precedes Macrocystic Changes in Acoustic Neuromas within Three Months of Stereotactic Radiosurgery

Delman, B. N.[1]·Carai, A.[1,2]·Germano, I.[1]
[1]Mt. Sinai Medical Center, New York, NY, [2]Presidio Ospedaliero Marino, Caligari, ITALY.

Purpose
To identify the pattern of changes in intralesional enhancement that acoustic neuromas undergo in the months following stereotactic radiosurgery (SRS).
Materials & Methods
We evaluated 24 patients with acoustic neuromas diagnosed by MRI for changes in tumor quality and size following SRS. Standard imaging protocol includes either thin-section or volumetric post-gadolinium images. Measurements of tumor volume were obtained in axial and coronal planes by calculating the sum of cross-sectional area on each image. Enhancement pattern for each tumor at three months was characterized in terms of "soap-bubble" appearance: a) "no bubble", indicating homogeneous enhancement; b) "microbubbles," indicating reduced intensity following contrast without discrete cavities; and c) "large bubbles," reflecting discrete cavities.
Results
The most common pattern was microbubbles, seen in 18/24 (75%) at three months. This was manifest as a nearly ground glass pattern centrally reflecting overall reduction in enhancement in the center of neuromas with sparing at the periphery. Large bubbles were seen in 4/24 (17%), and the no bubble pattern was identified in 2/24 (8%). Regarding volume changes, there was approximately 34% expansion of the tumors on average at three months, reflecting a significant portion of the enlargement that is typically seen in the first six months exams compared with baseline studies.
Conclusion
We believe the "microbubble" pattern reflects early fine cavitary change that is particularly prominent at three months. The imaging appearance is proposed to reflect volume averaging between i) small cavitary areas that do not enhance, and ii) surrounding parenchyma that does enhance. We further propose that the large bubble pattern represents one end of the transformation spectrum, in which microcavities coalesce into larger nonenhancing portions. At the other end of the spectrum are the lesions which lack bubbles, which may be evolving more slowly but which may go on to develop cavitation later.

MR Perfusion in Diagnosis of Intraparenchymal Hematoma with Underlying Tumors

Shankar, J. J. S.
QE II Hospital
Halifax, NS, CANADA.

Purpose
The intracranial hematoma could be either idiopathic/primary or secondary to underlying malignant tumors. The imaging appearance gets complicated due to the presence of a large hematoma. The usual sequence of investigation for intraparenchymal hematoma in our institution is plain head CT and MRI with gadolinium to rule out underlying etiology of the tumor. Most of the time the MRI is done in the subacute phase of the hematoma. Due to T1 hyperintensity of the hematoma and patchy enhancement of the hematoma, detection of underlying tumor is extremely difficult. We describe findings of MR perfusion (MRP) done in patients with intraparenchymal hematoma.
Materials & Methods
A retrospective review of MRP in consecutive patients who had MR perfusion done for the investigation of intraparenchymal hematoma in last six months. Routine, postgadolinium images and MR perfusion of these patients were analyzed for possibility of underlying tumor as a possible cause of hematoma. All these patients were followed up on imaging or were operated upon for evacuation of hematoma. Perfusion parameters of cerebral blood volume (CBV) and cerebral blood flow (CBF) and presence and pattern (nodular versus peripheral) of enhancement were recorded for each patient. Sensitivity, specificity, positive and negative predictive values were calculated for each of these parameters to predict the diagnosis of the tumor on followup.
Results
Total of 10 patients (M 7; F 3; Mean age: 61.7 years) with lobar hematoma underwent MRP. The sensitivity, specificity, positive and negative predictive value of both increased CBF and CBV was all 100%. Sensitivity, specificity, positive and negative predictive value for presence of enhancement on postcontrast images were 80, 20, 50, 50%. Sensitivity, specificity, positive and negative predictive value of presence of nodular pattern of enhancement on the postcontrast study were all 60%.
Conclusion
MR perfusion showed very high sensitivity and specificity for diagnosis of underlying tumor as the cause of hematoma. Presence of enhancement also was highly sensitive by had a very low specificity. Since most of these patients undergo MRI brain with gadolinium on a routine basis, the addition of MR perfusion will help in increasing the sensitivity and specificity in the diagnosis of underlying tumor. To our knowledge, we are the first to report the role of MRP in identifying underlying tumor in cases of intraparenchymal hematomas.

Intravoxel Incoherent Motion MR Imaging for Differentiating Glioblastoma Multiforme from Primary Cerebral Nervous System Lymphoma

Suh, C.·Kim, H.·Lee, S.·Kim, N.·Choi, C.·Kim, S.
Asan Medical Center
Seoul, KOREA, REPUBLIC OF.

Purpose
There has been a resurgent interest in intravoxel incoherent motion (IVIM) MR imaging to obtain perfusion as well as diffusion information on lesions, in which the diffusion was modeled as Gaussian diffusion. We tested the predictive value of the perfusion and diffusion parameters derived from IVIM MR imaging in order to differentiate glioblastoma multiforme (GBM) from primary cerebral nervous system lymphoma (PCNSL). In addition, we aimed to evaluate the relation between IVIM MR imaging parameters and dynamic susceptibility contrast (DSC), dynamic contrast enhanced (DCE) MR perfusion imaging parameters.
Materials & Methods
The institutional review board of our institution approved this study and prior written informed consent for routine brain tumor MR imaging was obtained from all patients. Fifty-nine consecutive patients (33 men, 26 women, mean age 54.5 years) who had pathologically confirmed GBM and PCNSL prior to any treatment, were assessed using IVIM MR imaging. The IVIM method is based on a bi-exponential fit (*) of the relative signal obtained with the Stejskal-Tanner diffusion sequence for multiple b-values, which permits the extraction of the perfusion fraction (*f*) and the diffusion coefficient (D). We acquired 16 different b-values (0, 10, 20, 40, 60, 80, 100, 120, 140, 160, 180, 200, 300, 500, 700, 900 sec/mm2) that are acquired in three orthogonal directions using a 3T MR scanner and a 32-multichannel receiver head coil. Thus, this work is to evaluate the effect of different b-values on IVIM *f* and D for differentiating GBM from PCNSL. The best predictor for differentiating GBM from PCNSL was determined by receiver operating characteristic (ROC) curve analyses. We used maximum normalized cerebral blood volume (nCBVmax) from DSC MR perfusion imaging and maximum initial area under the curve at first 60 sec (IAUC60max) from DCE MR perfusion imaging to evaluate the correlation with IVIM MR perfusion parameters. Pearson's correlation analysis was used to assess the relation between *f*, D, and nCBVmax, IAUC60max.
Results
We enrolled 38 patients (64.4%) with GBM and 21 patients (35.6%) with PCNSL. The *f* was significantly higher in glioblastoma group (mean ± SD; 0.119 ± 0.024) than in PCNSL group (mean ± SD; 0.056 ± 0.013) ($p < 0.001$; 95% confidence interval: 0.0519, 0.0746). The D did not

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

significantly differ between two groups (P = 0.144). ROC curve analyses showed *f* to be an excellent predictor of differentiating glioblastoma multiforme from PCNSL (AUC, 0990; 95% confidence interval: 0.973, 1.000; cut-off value, 0.075), with a sensitivity of 97.4% and a specificity of 90.5% and a positive predictive value of 94.9% and a negative predictive value of 95.0%. Excellent correlation between *f* and nCBVmax ($p < 0.001$, r=0.832), good correlation between *f* and IAUC60max ($p < 0.001$, r=0.575) were found for all cases.

Conclusion

The perfusion-fraction (*f*) from IVIM MR imaging can be a potential, noninvasive imaging biomarker for differentiating GBM from PCNSL. Major advantages of IVIM MR imaging are acquisition of perfusion and diffusion imaging simultaneously, independence of intravenous contrast injection, and acquisition of true diffusion imaging separated from the perfusion effects.

Physiologic MR Imaging for Assessment of Nonenhancing T2 Signal Abnormalities before or after Treatment of Brain Tumors: Myoinositol and Apparent Diffusion Coefficient Values May Be More Helpful than Choline Ratios and Perfusion Imaging

Ison, C.·Kumar, A. J.·Ketonen, L.·Schellingerhout, D.·Jackson, E. F.·Hou, P.·Hamilton, J. D.
M. D. Anderson Cancer Center
Houston, TX.

Purpose

Contrast-enhanced MRI has been a mainstay in the evaluation of intracranial neoplasms, prior to and after management with surgery, radiotherapy and chemotherapy. The pattern and degree of enhancement have been utilized in order to characterize or distinguish malignant neoplasms from low-grade tumors and treatment-related changes. However, since up to a third of malignant intracranial neoplasms do not enhance, and treatment-related changes such as gliosis may not enhance, further diagnostic procedures are needed to better characterize nonenhancing lesions. Therefore, the purpose of the study was to evaluate the utility of various advanced quantitative MR imaging biomarkers in patients with nonenhancing gliomas and treatment-related changes.

Materials & Methods

Twenty-five patients who underwent advanced brain tumor MR imaging for suspected intracranial neoplasm, based on nonenhancing T2 signal abnormalities, were identified retrospectively. Advanced imaging sequences that were acquired included: diffusion tensor imaging, gradient echo dynamic susceptibility contrast (DSC) perfusion imaging, and MR spectroscopy utilizing echo times of 35 and 144 ms. The specific metrics evaluated included DSC negative enhancement integral, DSC relative cerebral blood volume, Cho/Cr ratio, Cho/NAA ratio, myoinositol greater the 75% of the creatine peak height and the apparent diffusion coefficient (ADC) value. The accuracy of the overall protocol in distinguishing between treatment effects, low-grade (I & II) tumor, intermediate-grade (III) tumor, and high-grade (IV) tumor was assessed based on radiologist report, following determination of the actual histologic diagnosis, or if pathology was lacking whether the presumed diagnosis was confirmed based on three-six months of follow-up imaging (e.g., treatment changes resolved). In addition, the individual parameters between these groups were tested with the Fisher's exact test for discrete variables and the unpaired Students *t*-test for continuous variables.

Results

Of the presumed diagnosis, five cases of treatment effects were suspected (two of which were histologically sampled); four cases of high-grade tumor were suspected (two sampled); four cases of intermediate grade tumor were suspected (three sampled); and 12 cases of low-grade tumor were suspected (seven sampled). Overall, the nonenhanced advanced brain tumor imaging protocol had an accuracy of 12/14 (86%) based on the histopathologic diagnosis. The presumed diagnosis accuracy based on follow-up imaging or actual histopathologic diagnosis was 22/25 (88%). All inaccuracies were in the first half of patients imaged. Among the individual imaging parameters, the presence of an elevated myoinositol peak had the greatest degree of accuracy in distinguishing low-grade tumors (92%) from treatment-related effects (0%; $p = 0.0008$) and distinguishing low-grade tumors from high-grade tumors (25%; $p = 0.05$) and there was a trend for distinguishing between low-grade tumors versus combined intermediate and high-grade tumors (50%; $p = 0.06$). Apparent diffusion coefficient values were useful in distinguishing low-grade tumors versus treatment effects (1.5+/-0.5 versus 0.87+/-0.43xe-3 mm^2/s; $p = 0.02$). The other individual advanced brain imaging parameters were not significantly different between groups.

Conclusion

Advanced brain tumor MR imaging for nonenhancing lesions demonstrated a high degree of accuracy in distinguishing between the different tumor grades and treatment effects. Myoinositol and ADC values were the best predictor of histologic diagnosis.

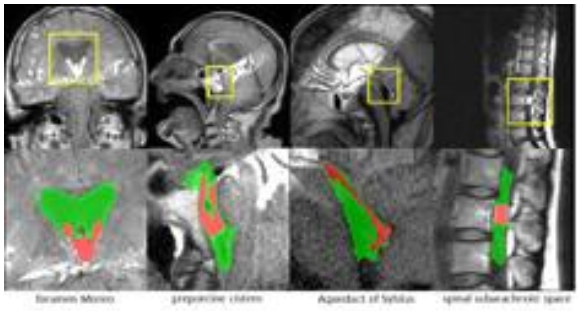
Development of an Automated Quantitation Method for Cerebrospinal Fluid Dynamics in the Cerebral Ventricles and the Spinal Subarachnoid Space Using MR Imaging Spin Labeling Technique

Shiodera, T.[1]·Nitta, S.[1]·Takeguchi, T.[1]·Yui, M.[2]·Yamashita, Y.[2]·Yamamoto, T.[2]·Yamada, S.[3]
[1]Toshiba Corporation, Kawasaki, JAPAN, [2]Toshiba Medical Systems Corporation, Tochigi, JAPAN, [3]Tokai University Oiso Hospital, Kanagawa, JAPAN.

Purpose
Using the time-spatial labeling inversion pulse (Time-SLIP) technique, a regional cerebrospinal fluid (CSF) dynamics can be traced without using contrast medium. Previous studies have evaluated visual assessments of CSF dynamics using the Time-SLIP technique. The objective of this study is automated quantitation of CSF dynamics in the cerebral ventricles and the spinal subarachnoid space using the Time-SLIP technique.
Materials & Methods
A series of 2D images with incremental inversion recovery times was obtained using 1.5T MRI scanner with Time-SLIP sequence. Observation regions were the foramen Monro, the prepontine cisterns, the aqueduct of Sylvius and the spinal subarachnoid space. These regions of interest were automatically outlined based on signal intensity analysis and shape of region. Subsequently, labeled CSF regions were further detected using the image binarization method. Average speed of the labeled CSF region was calculated using a regression line fitting. To evaluate the proposed method, experiments comparing the average speed and visual assessment by three neurosurgeons were conducted. Correlations between the proposed method and manual annotations of the average speed were evaluated in the spinal subarachnoid space.
Results
Seventy-nine datasets including 76 patients with various diseases (idiopathic normal pressure hydrocephalus, secondary normal pressure hydrocephalus, cerebral infarction, etc.) and three healthy volunteers for intracranial CSF dynamics, and 19 datasets from three healthy volunteers for the spinal subarachnoid CSF dynamics were studied. The proposed method detected the labeled CSF dynamics as shown in Figure 1. For cerebral ventricles, Table 2 shows correlation of the average speed between visual assessment and the automated quantitation method in these regions. Concordance ratios were 87 to 91%. For the spinal subarachnoid space, the correlation factor between the proposed method and manual annotations was $R2 = 0.83$ ($p < 0.001$). The processing time was less than three seconds.



comparison results between average speed and visual assessment

observation region	visual assessment results by neurosurgeons / average speed by the proposed method [mm/sec.]		
foremen Monro	no reflux	slow reflux	normal reflux
	0.40 ± 0.30	1.20 ± 0.62	3.06 ± 0.45
prepontine cisterns	no movement	normal movement	-
	0.55 ± 0.25	1.23 ± 0.49	-
aqueduct of Sylvius	slow movement	normal movement	fast movement
	0.22 ± 0.26	1.09 ± 0.54	3.68 ± 1.66

Conclusion
This paper presented a new automated quantitative method of CSF dynamics using the Time-SLIP technique.

KEYWORDS: Cerebrospinal fluid, MR imaging, image post-processing technique

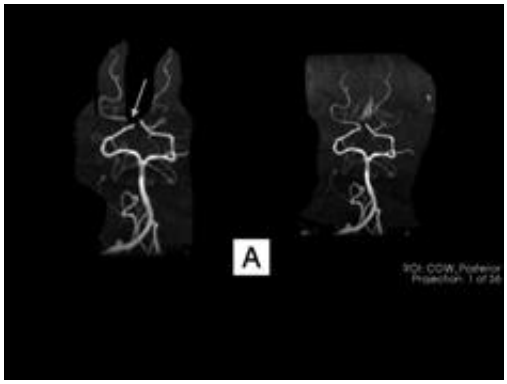
Feasibility of Creating Intracranial MR Angiography Maximum Intensity Projections Using Automated Processing Tools

Dobre, M. C.[1]·Seeger, C.[2]·Brost, A.[2]·Fischbein, N.[1]·Han, Z.[2]·Maclaren, J.[2]·Vos, S. B.[2]·Hornegger, J.[3]·Bammer, R.[2]
[1]Stanford Hospitals and Clinics, Stanford, CA, [2]Stanford University, Stanford, CA, [3]Friedrich Alexander University Erlangen Nuremberg, Erlangen, GERMANY.

Purpose
The process of manually creating rotational maximum intensity projection (MIP) images of the intracranial vessels is performed by MR technologists at our institution and is laborious, time-consuming and inefficient. It may take as long at 10 minutes to complete these reformats depending on the experience of the technologist and the number of desired projections, and on occasion the technologist may fail to create MIPs when they are distracted by more pressing patient care needs. Software that could automatically generate MIPs from source MRA data would improve MR technologist workflow and efficiency and should produce reliably available images of consistent quality.
Materials & Methods
We implemented a software package (RAPID) which is able to automatically process raw MRA data based on a cutout MIP ROI from an atlas which is registered to an individual patient. We tested this software in the clinical setting on MRA data acquired using standard time-of-flight (TOF) techniques on clinical 1.5T and 3.0T scanners. A board-certified radiologist and a board-certified neuroradiologist jointly reviewed and qualitatively compared 32 MIPs of the COW obtained in both the inpatient and outpatient setting between 10/01/2012 and 10/26/2012.
Results
RAPID generates five different rotational MIPs: entire circulation, anterior circulation, posterior circulation, anterior left Circulation and anterior right circulation of the circle of Willis (COW). Out of 32 MRAs, RAPID created equal or better quality MIPs in all but three instances, two of which were scored as only minor quality flaws. In 11 instances RAPID generated MIPs which offered clearer visualization of the posterior circulation and were less error-prone in patients who had complete vessel occlusion, such as patients with Moyamoya. Figure 1 shows a MIP of the COW created by an MR technologist with an artificial defect in the right PCA (arrow) and the comparison MIP generated by RAPID without this error.



Conclusion
The RAPID software successfully created rotational MIPs of the COW from MRAs obtained using standard TOF techniques on clinical scanners. These MIPs were equivalent in almost all instances to or of better quality than MIPs created by the MR technologist. Introducing fully automated, software generated MIPs into clinical practice is possible and may results in improved technologist workflow and fewer interpretive errors by the radiologist.

Assessment of Image Quality of Half Dose CT Scans Utilizing SafeCT Processing

Agarwal, V.·Delfyett, W. T.·Hughes, M. A.·Mettenburg, J. M.·Shah, R. R.·Tailor, D. R.·Deible, C. R.
University of Pittsburgh Medical Center
Pittsburgh, PA.

Purpose
There has been exponential growth in the use of CT imaging in the past decade due to technical advances, improved diagnostic accuracy and medico legal pressures. CT is now an indispensable part of diagnostic medicine. Although it has replaced more invasive and expensive tests, the growth in CT use has been accompanied by an unavoidable increase in cumulative radiation exposure. There is a clear need for simple yet effective ways to reduce dose while maintaining diagnostic image quality. The purpose of this study is to evaluate the use of a three-dimensional, nonlinear, postprocessing reconstruction noise reduction algorithm (SafeCT, MedicVision) to determine whether radiation dose can be decreased without compromising diagnostic image quality.
Materials & Methods
Under an IRB-approved protocol, adult patients scheduled for clinically indicated noncontrast CT exams of the head underwent a second, half dose CT scan following the clinical exam. The tube current for the research scan was adjusted to have 50% lower dose than the clinical scan. The low dose data then were reconstructed with a three-

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

dimensional, nonlinear, postprocessing reconstruction noise reduction algorithm (SafeCT, MedicVision). Each SafeCT processed exam then was displayed side by side with its full dose counterpart in random left/right order blinded to 5 CAQ neuroradiologist reviewers. For each exam, reviewers rated the images based on five questions about image quality and diagnostic value on a scale of one to five. The results then were unblinded and converted into a five-point scale where scores above three indicated superiority of the SafeCT processed exam and scores below three indicated superiority of the full dose exam.
Results
A total of 33 patients were enrolled and underwent both full dose and half dose noncontrast CT examinations of the head. Median and mean values were computed for each reviewer by each question. A bootstrap method then was used to compute the 95% confidence interval for the mean. In this study, a response value equal to three emphasizes that the two methods are equivalent. In fact based on mean values as well as the median, most raters gave a value of three for each question meaning they consider both methods as being equivalent based on rating questionnaires definition. The 95% confidence interval for the majority of reviewers and questions were narrow suggesting that the variability of ratings was very small. Higher variability was seen for one of the five reviewers for all questions as well as for question number five for all reviewers.
Conclusion
Although there is slight variability amongst the raters, the ratings of the reviewers are close to the value of three as indicated by both the mean and the median suggesting that there is no statistically significant difference between the full dose and half dose scans in terms of image quality and diagnostic acceptability. Therefore, the three-dimensional, nonlinear, postprocessing reconstruction noise reduction algorithm (SafeCT, MedicVision) used in this study can be a simple yet effective strategy to reduce radiation dose while maintaining diagnostic image quality.

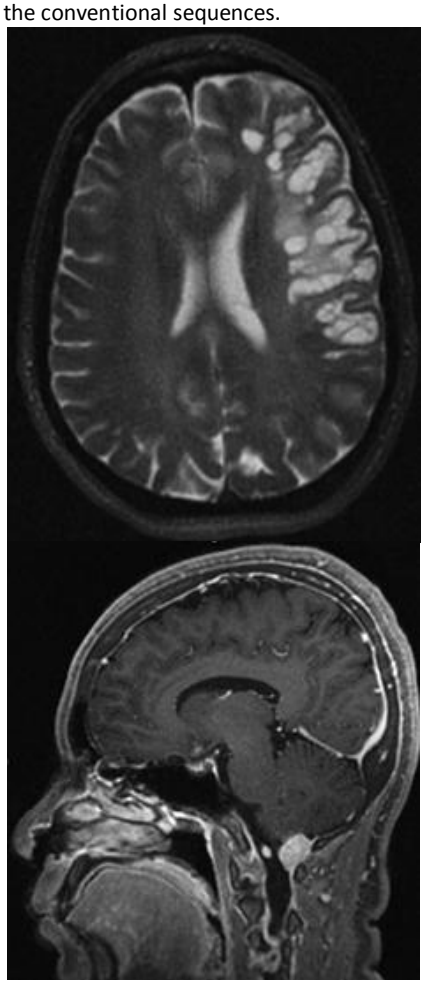
Silent Ultrashort TE MR Imaging: Initial Experiences with a New Clinical Sequence

DeLano, M. C.[1,2,3]·Sun, W.[4]·Akao, J.[4]·McKinnon, G.[4]·Close, O.[1]·King, K.[4]
[1]Michigan State University, Grand Rapids, MI, [2]Advanced Radiology Services, PC, Grand Rapids, MI, [3]Spectrum Health, Grand Rapids, MI, [4]General Electric Health Care, Waukesha, WI.

Purpose
Acoustic noise of MR imaging has important safety and comfort implications, particularly when imaging at higher field strength. Pioneering work by Bydder et al explored the use of ultrashort TE imaging in multiple body regions. We report the clinical feasibility of brain imaging with silent ultrashort TE 3D T1- and T2-weighted commercial sequences at 3T, and discuss the associated image contrast features and patient acceptance.
Materials & Methods
Seven consecutive patients scheduled for routine pre and postcontrast MR of the brain were recruited for evaluation of these sequences in preparation for FDA 510K submission for use on a commercial 3T MR system (GE Healthcare MR 750W, Waukesha, WI). Multiple weightings were obtained and image quality and contrast features were compared to conventional sequences. Patient tolerance and experience with the silent sequences was assessed subjectively at the end of the scanning session.
Results
Gray-white differentiation, lesion to background contrast, and contrast enhancement features of the silent sequences demonstrated comparable conspicuity to conventional sequences. There was no statistical difference in the volume or intensity of enhancing tissue following intravenous contrast between the Silent T1 and conventional Bravo T1 sequences in those patients with enhancing lesions. Signal to noise was less with the silent sequences. All patients preferred the silent sequences to the conventional sequences.



Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Figures: Silent T2 with left frontal dilated perivascular spaces and Silent T1 postcontrast with foramen magnum meningioma.

Conclusion

Robust silent imaging can be performed with multiple weightings at 3T with comparable image contrast features to conventional 2D and 3D volumetric sequences. Reduction or elimination of noise improves patient acceptance, facilitates interaction with and monitoring of patients during scanning. These features may be helpful in reducing anxiety and improving acceptance of MR evaluation and warrant further investigation.

KEYWORDS: MR imaging, 3D imaging

Feasibility of Utilizing Gadoxetate Disodium (Eovist) as a Cranial Contrast Agent: Preliminary Experience in Renally-Impaired Patients Requiring Brain Imaging

Pezeshk, P.·McKinney, A. M.·Rykken, J.
University of Minnesota
Minneapolis, MN.

Purpose

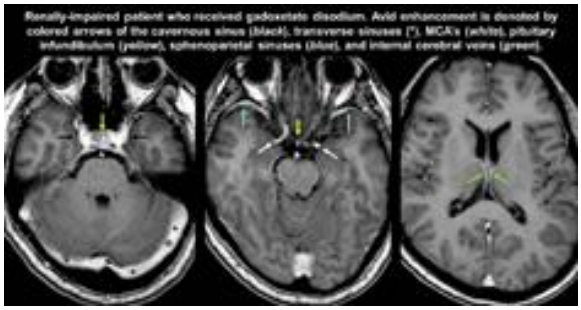
Nephrogenic systemic fibrosis (NSF) occurs in severely renally-impaired patients receiving intravenous gadolinium-based contrast agents (GBCA), particularly the Group 1 "nonionic linear" agents, but has not been reported in newly approved Group 3 agents, such as gadoxetate disodium (“Eovist”, Bayer Healthcare Pharmaceuticals, Wayne, NJ). Eovist has been claimed to be effective at lower, approved doses of GBCA (0.025 mmol/kg, ¼ of recommended standard dose) per the manufacturer, while other factors could mitigate the development of NSF in at-risk patients receiving Eovist such as: 1) "class" (it is ionic), 2) stability: (it has the highest thermodynamic and conditional stability in an FDA-approved GBCA, although macrocyclic agents have higher “kinetic” stability), and 3) it is the only FDA-approved GBCA with 50-50% renal-biliary/hepatic excretion. As Eovist has traditionally been utilized only for body imaging, our purpose was to evaluate the feasibility of visualizing enhancement of cranial structures utilizing Eovist in patients in whom using GBCA was medically necessary.

Materials & Methods

Over a 2-year period, intravenous Eovist was administered in 11 patients for a 10 cc dose postcontrast MRI (two with normal GFR due to sensitivity to other agents, and nine with renal impairment, performed out of medical necessity), imaged by 1.5T axial and coronal 5 mm-thick postcontrast gradient-echo T1WI (five minute delay). The images were reviewed separately by three staff neuroradiologists, scoring the presence/absence of enhancement of 11 structures [+, -, or +/- (indeterminate)]. Two patients underwent concomitant spine imaging.

Results

The mean patient age was 66.2 years, and the GFR range for the nine patients with renal impairment was 20-43 over the month leading up to the MRI. All three reviewers noted avid, definite enhancement in all 11 patients (100%) within the: cavernous sinuses, transverse sinuses, cavernous sinus, straight sinus, superior sagittal sinus, and nasal/ethmoidal mucosa; the sphenoparietal sinus (82-91%), internal cerebral veins (91-100%), pituitary infundibulum (64-91%), choroid plexi(64-82%), and middle cerebral arteries (65-73%) enhanced with lesser frequencies. Interobserver kappa was excellent, ranging from 0.613-0.732, p<0.0001. Only one of these 11 patients exhibited an enhancing cranial abnormality (meningioma). In two patients also undergoing spine imaging, the abnormalities (meningioma and metastasis) in both were well visualized, and the basivertebral plexi avidly enhanced.



Conclusion

Eovist may be a feasible alternative contrast agent for brain MR imaging. However, future studies should compare to controls, assess efficacy in assessing enhancing cranial lesions, and should prospectively assess the safety of this agent in renally impaired patients.

Initial and Final Area under the Curves Ratio Derived from Dynamic Contrast-Enhanced T1-Weighted Perfusion MR Imaging in Pathologically Proven Recurrent Glioblastomas

Chung, W.[1]·Kim, H.[1]·Jahng, G.[2]·Kim, N.[1]·Kim, S.[1]·Kim, D.[1]
[1]University of Ulsan College of Medicine, Asan Medical Center, Seoul, KOREA, REPUBLIC OF, [2]Kyunghee University School of Medicine, Seoul, KOREA, REPUBLIC OF.

Purpose

To determine whether an initial and final area under the curves ratio (AUCR) derived from dynamic contrast-enhanced (DCE) perfusion MR imaging can be a imaging biomarker for distinguishing recurrent glioblastoma (RGM) from radiation necrosis (RN) and to compare diagnostic accuracy with commonly used model-free DCE parameters.

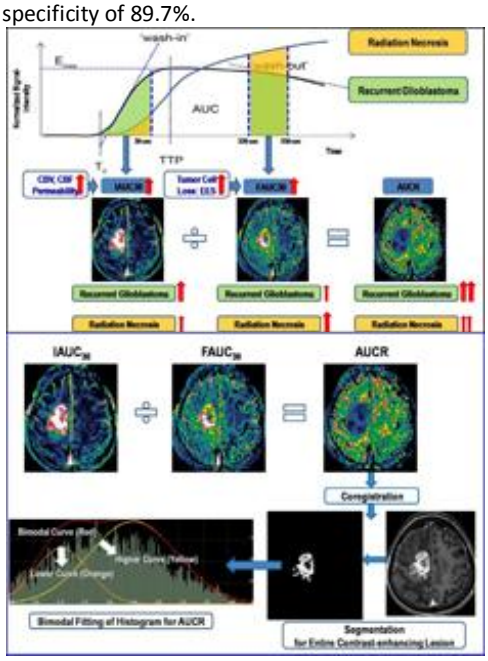
Materials & Methods

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Our institutional review board approved this retrospective study. Fifty-seven consecutive patients who had pathologically confirmed RGM or RN were assessed using conventional and DCE MR imaging. Bimodal histogram parameters of initial area under the curve at 30 sec (IAUC30), at 60 sec (IAUC60), and at 120 sec (IAUC120) and AUCR, which included mean value at higher curve ($mIAUC30_H$, $mIAUC60_H$, $mIAUC120_H$, and $mAUCR_H$) and 90th percentile cumulative histogram cutoffs ($_{90th}$IAUC30, $_{90th}$IAUC60, $_{90th}$IAUC120, and $_{90th}$AUCR), were calculated and were correlated with the final pathology. The best predictor for differentiating RGM from RN was determined by receiver operating characteristic (ROC) curve analyses.

Results

Fifty-seven study patients were classified as having either RGM (n = 32, 56.1%) or RN (n = 25, 43.9%). There were not significant differences between the two groups with respect to demographic data. There were statistically significant differences in all of the IAUC and AUCR parameters between the RGM and the RN patient groups ($P < .05$, each). Receiver operating characteristic curve analyses showed the $mAUCR_H$ to be the best single predictor of RGM, with a sensitivity of 95.2% and a specificity of 89.7%.



Conclusion

A bimodal histogram analysis of AUCR derived from DCE perfusion MR imaging can be a potential, noninvasive imaging biomarker for differentiating RGM form RN.

eP-84

RASER: a pulse sequence for whole-brain bolus tracking at high frame rates

Jonathan, S. V.[1]·Vakil, P.[1]·Jeong, Y. I.[1]·Menon,, R. G.[2]·Ansari, S. A.[1]·Hurley, M. C.[1]·Bendok, B. R.[1]·Carroll, T. J.[1]
[1]Northwestern University, Chicago, IL, [2]Feinberg School of Medicine, Chicago, IL.

Purpose

Current DSC MRI bolus tracking implementations use a temporal resolution of no more than two sec to adequately characterize a contrast agent bolus, with tradeoffs in SNR, spatial resolution, and volume coverage. We introduce 3D RAZIR, a pulse sequence that obtains 76-slice whole-brain perfusion measurements at 1.7 mm^3 isotropic voxel resolution despite using a temporal resolution of 10.3 sec for bolus tracking.

Materials & Methods

Sequence design: 3D RAZIR uses in-plane radial sampling and through-plane 3D GRE EPI Cartesian sampling to produce a cylindrical *k*-space(Figure 1). Consecutive volumes are acquired in 10.3 sec for bolus tracking. Dynamic bolus information is recovered at 160 msec per frame prior to perfusion analysis using sliding window reconstruction. *Subjects*: One patient with angiographically-confirmed Moyamoya disease was recruited with IRB approval. *Image acquisition*: In vivo bolus tracking was performed using 3D RAZIR and a typical 2D GRE EPI pulse sequence(voxel size 1.7 × 1.7 × 5.0 mm^3) as a reference standard with a 3.0 T MR scanner (Tim Trio, Siemens AG, Erlangen, Germany). 3D RAZIR scan parameters: second injection, TE/TR = 36/81 ms, flip angle = 45°, slices = 76, voxel size = 1.7 × 1.7 × 1.7 mm^3, repetitions = 12. Images were acquired with a single-dose injection of 0.1 mmol/kg Gd DTPA at 4 mL/sec. *Data analysis*: Sliding window reconstruction was used to increase the reconstructed frame rate of 3D RAZIR from 10.3 sec to 0.16 sec per measurement using a sliding window factor of 64 before perfusion analysis. Both acquisitions were processed using a stand-alone program in Matlab to produce parametric maps of relative cerebral blood flow(rCBF), relative cerebral blood volume(rCBV), and mean transit time (MTT).

Results

Figure 2 compares coronal, sagittal, and axial perfusion maps in 3D RAZIR(top) and the 2D GRE EPI reference (bottom). Increased coverage in 3D RAZIR allows for fine resolution of the perfusion metrics in the through-plane direction while the reference is blurred. Using an ROI analysis, we obtained gray/white matter CBF ratios of 2.38 in the reference and 2.18 in 3D RAZIR, in close agreement with literature values.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

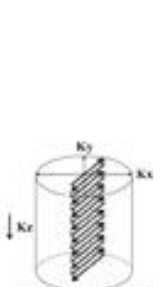

FIGURE 1. In-plane radial and through-plane Cartesian sampling is used to produce a cylindrical 3D *k*-space. Each TR acquires a single radial view in-plane during which all *k*$_z$ partitions are sampled using a 3D GRE-EPI readout.

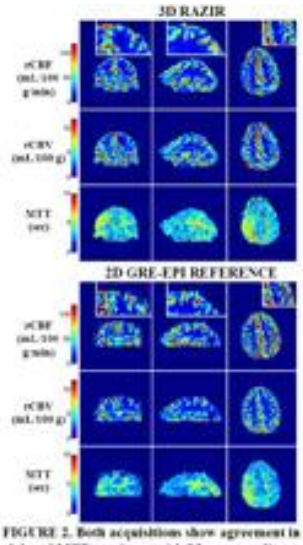

FIGURE 2. Both acquisitions show agreement in contrast and delayed MTT consistent with Moyamoya disease. 3D RAZIR more clearly illustrates the pathology with isotropic voxels.

Conclusion
3D RAZIR is able to obtain whole-brain perfusion measurements with good reference standard agreement. Sliding window reconstruction permits the use of an extended temporal acquisition window without sacrificing SNR for bolus tracking. To our knowledge, no other perfusion technique is able to obtain a spatial resolution higher than our technique without the use of parallel imaging.

Digital Subtraction CT Angiography of the Brain: Evaluation of Postcontrast Venous Phase Mask versus Precontrast Mask

Mends, F.·Davis, A.
New York University-Langone Medical Center
New York, NY.

Purpose
Digital subtraction CT angiography (DS CTA) is improved by using a precontrast low-dose CT mask to subtract bone from the images during postprocessing. Unfortunately, patient movement may occur during the delay between the precontrast mask and the completion of the CTA and can be further exacerbated by the administration of intravenous contrast. A previous study suggested that a postcontrast, venous-phase mask for cervical CTA may be utilized as an alternative, but did not compare directly with standard technique. We evaluated the feasibility of using a postcontrast, venous-phase, low-dose mask for cerebral DS CTA. This simplified technique may reduce patient motion degradation and enhance image quality by improved bone subtraction. This approach has the added advantage of the postcontrast CT mask serving as a diagnostic CT venogram or postcontrast head CT if standard acquisition parameters are used.
Materials & Methods
Fifteen cerebral DS CTA studies performed with a low-dose, postcontrast, venous-phase mask and 15 studies performed with a standard low-dose, precontrast mask were acquired during the study period. Imaging was performed on a 64-slice CT scanner (GE-VCT, Milwaukee WI). Other than mask timing all acquisition parameters were identical. Postprocessing was performed with *syngo* Via NeuroDSA(Siemens Medical Solutions, Erlangen, Germany) utilizing factory default settings. Subtracted volume rendered technique and maximum intensity projection radial rotating images from each group were created with identical postprocessing parameters. The quality of bone subtraction and vessel appearance were graded using predetermined criteria by three independent blinded observers. The arterial and venous opacification (HU) was measured at the most dense supraclinoid ICA and the torcula respectively utilizing the source images for all studies. Radiation dose and mask delay time was determined. These parameters were compared with image quality to determine the optimal time delay for postcontrast mask acquisition.
Results
Analysis of observer data suggests equivalent bone subtraction utilizing either pre or postcontrast mask technique. Vascular image quality particularly for segments adjacent to bone is equivalent. Medium and small vessel detail is preserved. Mean total radiation dose is slightly higher for the venous mask group. Mask delay time ranged from 21-67 seconds, mean 44 seconds. Postcontrast mask inadvertent arterial subtraction occurred in only one case in which the mask was obtained at a 23-second delay and arterial opacification remained dense measuring 299 HU. All other postcontrast mask arterial and venous HU measurements were less than 200 HU at 24-second delay or greater. This is well below the default bone removal threshold of 300 HU.
Conclusion
Simplified postcontrast venous-phase mask for cerebral DS CTA provides bone subtraction and vascular conspicuity equivalent to standard technique using a precontrast mask. The slight difference in radiation dose could introduce bias although the effect is thought to be negligible. Optimal time for the postcontrast mask is highly variable secondary to individual hemodynamic differences. The one inadvertent arterial subtraction artifact observed here supports using an approximate 45-second delay. Use of a low-dose protocol maintains ALARA standards. A postcontrast mask can provide additional information via a diagnostic CT venogram or contrast-enhanced parenchymal study if desired.

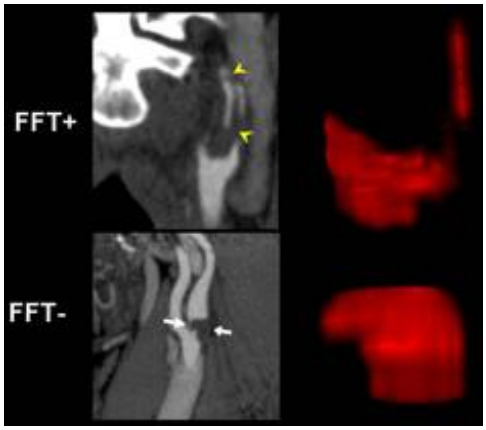
Can *Shape Analysis* Differentiate Proximal Internal Carotid Artery *Thrombus* from Atherosclerotic *Plaque* in Patients Evaluated with CT Angiography for Stroke or Transient Ischemic Attack?

Lum, C.·Thornhill, R.·Jaberi, A.·Stefanski, P.·Torres, C.·Petrcich, W.·Momoli, F.·Dowlatshahi, D.·Ottawa Stroke Research Group (OSRG)
University of Ottawa-Ottawa Hospital Research Institute
Ottawa, ON, CANADA.

Purpose
Patients presenting with transient ischemic attack or stroke imaged with CTA rarely demonstrate free-floating intraluminal thrombus (FFT). It is difficult to distinguish FFT from carotid plaque, but the distinction is critical as management differs. Visually, FFT has been described as appearing more elongated as opposed to plaque. However, there are false positives using only qualitative criteria. More advanced imaging analysis techniques such as shape analysis have been used for evaluation of hippocampi but have not been applied to CTA findings. There is sparse ultrasound literature evaluating shape analysis of carotid plaque morphology as an attempt to better stratify patients with stenosis. Ex vivo analysis of endarterecomy specimens has been performed to evaluate simple criteria such as ulcers and smoothness. Shape analysis has not been used to analyze vascular pathology identified on CTA. Thus, our goal was to apply shape analysis techniques to a population with vascular disease identified on CTA. Our study was to determine whether quantitative shape analysis can accurately differentiate FFT from atherosclerotic plaque.
Materials & Methods
Following Institutional Review Board approval, we collected 23 consecutive cases of suspected carotid FFT seen on CTA (13 men, 65 ± 10 years; 10 women, 65.5 ± 8.8 years). True positive FFT cases (FFT+) were defined as filling defects resolving with anticoagulant therapy versus false positives (FFT-), which remained unchanged and were categorized as plaque. "Virtual endarterectomy" was performed independently by two fellowship-trained neuroradiologists. By consensus, the 3D lesion volumes were extracted from CTA source images and shape descriptors were computed. The five most discriminative features were used to construct ROC curves and to generate three machine learning classifiers. Average classification accuracy was determined by cross-validation.
Results
Follow-up imaging confirmed 16 FFT+ and 7 FFT- cases. Five shape descriptors delineated FFT+ from FFT- cases (two for axial, one for coronal and two for sagittal planes). The logistic regression model produced from combining all five shape features demonstrated a sensitivity of 87.5%, specificity of 71.4%, with an AUC = 0.85 ± 0.09. Average accuracy for each classifier ranged from 65.2-76.4%.



Conclusion
We identified five quantitative shape descriptors of carotid FFT. This 3D shape "signature" shows potential for supplementing conventional lesion characterization in cases of suspected FFT.

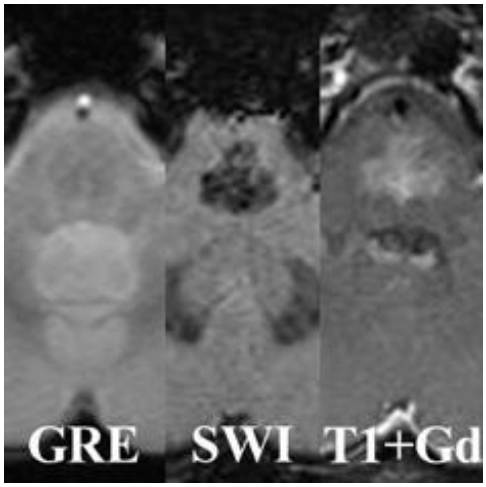
Susceptibility-Weighted MR Imaging: A Better Technique in the Detection of Capillary Telangiectasia when Compared to T2*-Gradient Echo

De Bruin, D. E.·Chaudhry, U. S.·Policeni, B. A.
University of Iowa Hospitals and Clinics
Iowa City, IA.

Purpose
Enhancing lesions on brain MRI can present a diagnostic quandary as both benign lesions such as capillary telangiectasia (BCT) and pathologic lesions such as demyelination or metastatic disease may appear similar. Stagnation of blood in the low-flow venous channels of BCTs results in susceptibility effect secondary to the increase in local deoxyhemoglobin. Both T2*-gradient-echo imaging (GRE) and susceptibility-weighted imaging previously have been demonstrated as valuable in the diagnosis of BCT. Because susceptibility-weighted imaging (SWI) is more sensitive to susceptibility changes than GRE, we aim to demonstrate an increased diagnostic value of SWI compared to GRE in making the diagnosis of BCT.
Materials & Methods
We retrospectively reviewed the MR images of 17 patients with a presumed diagnosis of BCT who were examined from June 2010 to September 2012. All patients had undergone MR imaging at 1.5T with T1, T2, FLAIR, GRE, SWI, and gadolinium-enhanced T1 sequences. Lesions were evaluated for the presence or absence of signal abnormality on each particular sequence.
Results
All 17 CBTs demonstrated distinct signal-intensity loss on SWI compared to 7/17 (41%) showing signal-intensity loss on GRE. The increased frequency of detection using SWI versus GRE is statistically significant ($z = 2.85$, $p < 0.01$; $\chi^2 =$

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

8.10, $p < 0.01$). Six of the lesions showed signal intensity changes on T1 and/or T2 while the remaining lesions were isointense to normal brain.



Conclusion

Capillary telangiectasias are more conspicuous on SWI than GRE and other precontrast MR imaging. In our review, there were no cases where GRE was positive and SWI was negative. Susceptibility-weighted imaging is a valuable tool in diagnosing these benign lesions which may otherwise be occult on noncontrast MR imaging, and should serve to increase diagnostic confidence.

Evaluation of Enhancing Multiple Sclerosis Brain Lesions with 3D T2 FLAIR and T1 Sequences

Stanton, C. L.[1]·Shapiro, M.[1,2,3]
[1]University of Miami, Miami, FL, [2]University of Central Florida, Orlando, FL, [3]Neuroimaging Winter Park, Winter Park, FL.

Purpose

To compare the relative utility of postcontrast 3D T2 FLAIR with 2D T1 spin echo (SE) or 3D T1 turbo spin echo (TSE) for the evaluation of enhancing lesions in patients with multiple sclerosis (MS).

Materials & Methods

One hundred patients were prospectively recruited based upon sequential presentation to undergo MRI for known or suspected MS at the outpatient imaging center Neuroimaging Winter Park (from December 2011 to December 2012). Scanning was performed on a Siemen's Verio 32-channel 3T machine. All 100 patients underwent standard MS protocol which included administration of intravenous contrast (0.05 mmol/kg gadopentetate dimeglumine) with subsequent acqusition of 3D T2 FLAIR followed by either 2D T1 SE or 3D T1 TSE sequences. Independent readers included an experienced CAQ neuroradiologist and a PGY4 radiology resident. Out of 100, a total of 14 patients (aged 16 to 53 years, one male) demonstrated a combined 34 enhancing lesions deemed to represent active MS plaques. These were categorized with respect to size, location, and relative conspicuity on a previously established four-point scale - with "0" being not visible, "1" being barely visible, "2" being clearly visible and "3" being strikingly visible. Differences in lesion conspicuity were compared using Wilcoxon ranked sum test and interobserver variability was compared using kappa statistics.

Results

p-value testing overall difference between FLAIR and T1 for reader 1: .0953. p-value testing overall difference between FLAIR and T1 for reader 2: .0708. *p-values were computed using a paired Wilcoxon ranked sum test. *Interobserver Variability* - k score for lesion conspicuity was .62 for the T1 sequence (good reproducibility) and .62 (good reproducibility) for the FLAIR sequence.

Lesion Conspicuity	# of Lesions	T1 *Mean Conspicuity (SD)*	3D T2 FLAIR *Mean Conspicuity (SD))*	p-value
Lesion size				
<5mm	26	1.96 (.58)	2.13 (.66)	NS
5-20mm	7	2.36 (.48)	2.56 (.45)	NS
Lesion location				
Cortical/Subcortical	5	2.20 (.57)	2.50 (.45)	NS
Periventricular WM	13	2.08 (.45)	2.30 (.48)	.09
Callosal/Pericallosal	4	1.88 (.63)	1.88 (.63)	NS
Deep WM	6	2.00 (.84)	2.08 (1.11)	NS
Posterior Fossa	5	2.00 (.71)	2.40 (.55)	NS

Conclusion

While comparison of enhancing MS lesions in overall conspicuity as well as in subgroup analysis did not meet statistical significance between the sequences this was likely due to a limited sample size. Despite this, we experienced instances where 3D T2 FLAIR was relatively more sensitive for detection particularly of subtle

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

subcortical lesions, a finding which has been suggested previously. As with noncontrast 3D T2 FLAIR, postcontrast 3D T2 FLAIR is certainly valuable for MS lesion localization. While T2 prolongation is the predominant mechanism for T2 FLAIR signal hyperintensity, T1 shortening from gadolinium also contributes. The frequent presence of T2 prolongation in both active and inactive MS lesions emphasizes that pre and postcontrast T1 sequences remain essential for confirming enhancement. As suggested by its utility in assessing other pathologies, we feel that acquisition of a postcontrast T2 FLAIR should be considered as a replacement to precontrast T2 FLAIR in standard MS protocols and our good interobserver reproducibility suggests a useful model to potentially assess this in larger studies.

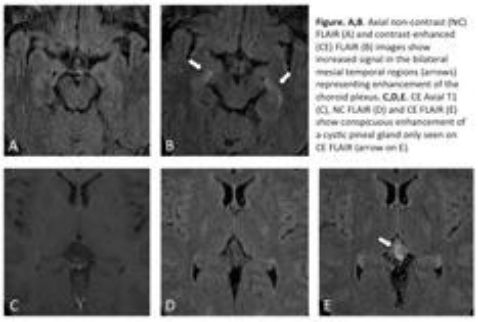
Normal Pattern of Intracranial Enhancement on Postcontrast FLAIR MR Imaging

Morales, H.·Radhakrishnan, R.·Vagal, A.·Qi, Z.
University of Cincinnati
Cincinnati, OH.

Purpose
Postcontrast FLAIR (CE FLAIR) has shown to be a valuable imaging modality in the assessment of lepto-meningeal disease. There is also increased interest in its use for acute stroke and tumors. Despite this, there is limited literature evaluating the normal pattern of enhancement on CE FLAIR in the adult brain. Our aim is to describe the normally enhancing structures on CE FLAIR, thus giving a reference point to avoid diagnostic pitfalls.
Materials & Methods
After institutional IRB approval, 44 patients (mean age: 48.3 ± 15 years) who had pre and postcontrast FLAIR images were selected between April and May 2012. All these patients had a normal MRI brain study. Two neuroradiologists and one radiologist-in-training evaluated the structures that showed enhancement on CEFLAIR and contrast T1-WI (CE T1). Areas that showed enhancement on CE FLAIR and no enhancement on CE T1 also were evaluated.
Results
Enhancement in the choroid plexus and the pituitary infundibulum was seen on CE FLAIR in all cases. Enhancement in the cavernous sinus (75%; 33/44) and pineal gland (75%; 33/44) was seen in the majority of cases. The pituitary gland (40.9%; 18/44) and nasal mucosa/turbinates (31.8%; 14/44) showed enhancement in some cases. Rarely, enhancement in the jugular bulbs (9%; 4/44), cortical veins (4.5%; 2/44) and dural sinuses (2.3%; 1/44) also was seen. In some cases, carotid arteries at the skull base (65.9%; 29/44) and the arteries of the circle of Willis (15.9%; 7/44) showed enhancement on CE T1, but none of these regions enhanced on CE FLAIR. Subtle ocular enhancement (choroid) was seen in most cases on CE T1 (79.5%; 35/44), no cases were found on CE FLAIR. Four cases of cystic pineal gland showed enhancement only on CE FLAIR.



Conclusion
Radiologists should be aware of the normal T1-shortening effect (positive enhancement) of gadolinium on CE FLAIR in the described structures. These findings can be used as a reference to avoid misinterpretations. For instance, increased signal in the mesial temporal region on CE FLAIR should not be confused for abnormal signal as this most likely represents choroid plexus enhancement; on the other hand, enhancement of the cortical veins, dural sinuses or the globes should prompt a search for pathology. Minimal leakage of gadolinium appears responsible for the enhancement only seen on CE FLAIR in some cystic pineal glands.

Safety and Efficacy of Gadoterate Meglumine in MR Imaging in Adult and Pediatric Patients with Central Nervous System Lesions

Maravilla, K.·SENTIO Investigators Group
University of Washington
Seattle, WA.

Purpose
To demonstrate superiority of gadoterate meglumine-enhanced MRI over unenhanced images for visualization of brain and spinal lesions (including tumor, vascular, inflammatory or infectious diseases) in adults and children.
Materials & Methods
Multicenter, randomized, double-blind, fixed-sequence [unenhanced T1 and T2 MRI followed by either gadoterate meglumine (Dotarem, 0.1 mmol/kg) or gadopentetate dimeglumine (Magnevist, 0.1 mmol/kg) T1-enhanced MRI], active comparator study (SENTIO study). Pediatric patients (aged ≥ two years) were assigned to the gadoterate meglumine group only. MR images of all patients were read by three off-site blinded independent readers. All patients also were evaluated by one on-site radiologist. The primary endpoint was lesion visualization with gadoterate meglumine-enhanced MRI comparing unenhanced images in up to five of the largest lesions

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

utilizing three co-primary endpoints: border delineation, internal morphology and degree of contrast enhancement. For each of the three endpoints, a score was computed by summing all lesion scores for a given patient. Each co-primary endpoint then was analyzed using a multiple regression model. Main secondary criteria were evaluated on-site for: lesion visualization, level of diagnostic confidence, image quality, signal intensity, number of lesions, comparison of gadoterate meglumine and gadopentetate dimeglumine for efficacy and clinical safety [including adverse events (AEs), injection site tolerance, changes in vital signs, electrocardiogram recordings and laboratory measures].

Results

A total of 402 patients were evaluable: 364 adults (245 gadoterate meglumine, 119 gadopentetate dimeglumine) and 38 children. The primary endpoint (lesion visualization postgadoterate meglumine enhanced MRI) as well as all three co-primary endpoints were significantly superior ($p<0.001$) for all independent readers when comparing enhanced images to unenhanced images (Table 1). This superiority of gadoterate meglumine enhanced imaging also was confirmed in analyses of all secondary endpoints by on-site evaluators. No statistically significant differences between gadoterate meglumine and gadopentetate dimeglumine were observed for all three co-primary variables for the three independent readers. Analysis of the pediatric group for all three independent readers showed mean scores for each of the three co-primary endpoints were higher for “enhanced” compared to “unenhanced” images. Both contrast agents were well tolerated. Related AEs were reported in 3.8% adult gadoterate meglumine and in 7.7% gadopentetate dimeglumine patients. The most common AEs were injection site pain, headache and nausea. No related serious AEs occurred.

Quantative Volumetric Followup of Patients with Acoustic Neurinomas

Shreiber, R.·Shreter, R.·Goldsher, D.
Rambam Medical Center
Haifa, ISRAEL.

Purpose

Serial MR studies of patients with acoustic neurinoma (AN) is vital in followup and evaluation of the efficacy of surgical or radiation treatment. The current method to evaluate the tumor size, based on linear measurements - this technique is evaluator-dependent, and requires repeating of the measurements by the same observer for best assessment of tumor progression. To enhance accuracy and objectivity of tumor measurements, we use software-generated volumetric measurements in follow-up studies of patients with AN.

Materials & Methods

All patients that were treated in our hospital for AN and had at least two follow-up MR studies in the last three years were included in the study. Semi-automated registration, segmentation and volumetric measurements at all points in time were performed using a new lesion managment package in the PACS system (Carestream Health, Rochester, NY). Correction of the automatic

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

segmentation was done using a live-wire software available on the same package. Each patient was reviewed by two experienced neuroradiologists, who performed postprocessing and lesion measurements. We compared the results obtained from the two independent measurements. Time-for-volume measurements, including refinement of the measurements, were recorded. T1-weighted axial or coronal sequences with gadolinium, were used.

Results

Nineteen patients (11 females and eight males) who were treated and followed up in our hospital were reviewed retrospectively. Age range was 27-76 years (mean = 55.7 years) at the time of the last follow-up study. Two to nine studies per patient (mean 3.9) were examined. The research included a total of 78 studies. The software segmented the lesions successfully in all 78 exams. Average volume of the AN was 2.074 mm^3 (range 0.43 to 19.51 mm^3), average largest linear dimension of the lesions was 24.24 mm (range 10.1 to 40.9). Postprocessing time was completed in less than one minute per lesion including corrections of the automatic segmentation. The difference of the volumetric measurements between the observers in all studies was less than 14% which corresponds to a linear accuracy of 4.4%. As lesions size was larger the difference in size between the observers was smaller.

Conclusion

Volumetric semi-automatic measurements of AC lesions allow accurate assessment for the followup of these patients. The possibility of registration between the exams further improves the confidence of the user in assessing tumor progression. Larger tumors that usually are more difficult for comparisons had better agreement between the observers.

Assessment of Iterative Reconstruction Levels on Pathology Detection in Reduced Dose CT Brain

Neelakantan, A.[1]·Iqbal, A.[1]·Aitken, S.[1]·Andrew, R.[2]·Forbes, K. P.[1]

[1]Institute of Neurological Sciences Glasgow, Glasgow, UNITED KINGDOM, [2]Philips Centre, Guildford Business Park Guildford, Surrey, UNITED KINGDOM.

Purpose

Acceptance of the ALARA (As-Low-As-Reasonably-Achievable) principle necessitates that imaging is performed with the lowest possible radiation dose. Recent studies have demonstrated the value of iterative reconstruction (IR) technology in reducing radiation dose in CT of the brain whilst maintaining image quality in normal subjects; however to the best of our knowledge no other studies have examined pathologic areas. We set out to determine the diagnostic impact of varying levels of IR on reduced dose CT brain in subjects with intracranial pathology.

Materials & Methods

Thirty subjects (mean age 59.2 years, SD20.69; 16M; 14F) with intracranial pathology [cerebral infarct: acute (n = 8), chronic (n = 5), intracranial hemorrhage (n = 5), subarachnoid hemorrhage (n = 3), abscess (n = 2), Chiari (n = 1) and tumors (n = 6)] were identified from consecutive patients who had undergone CT brain with reduced dose (Philips, Brilliance 64 scanner, 64 slice, 200 mAs, 120 kVp, 1 mm slice thickness, 25 noncontrast, five contrast examinations). Data were reconstructed using a variety of iDose (Philips) IR and filtered back projection (FBP) blends (iDose 0-5, varying from 100% FBP to 60% IR). Datasets were blinded analyzed qualitatively by two neuroradiologists, who declared their preferred image dataset for pathology detection (Philips Advantage workstation; axial 4 mm slices, window width of 70HU and center of 35 HU). Interobserver variability was measured by using linear-weighted kappa statistic. Quantitative assessment of image noise (SD) and contrast-to-noise ratio (CNR) of pathology to background were measured and correlated to iDose level.

Results

Qualitative assessment yielded a mean preference of iDose level 2.8 +/- 0.85 for pathology detection (iDose 2: 30% IR, 70% FBP; iDose 3: 40% IR, 60% FBP) (observer 1: mean 3.1+/-1.0; observer 2: mean 2.6 +/-1.1; kappa: 0.11). No lesion/diagnosis was missed on any of the reconstructions. Quantitative assessment demonstrated reducing noise ($r2 = 0.98$;$P<0.05$) and increasing CNR of pathology to background, with increasing iDose level ($r2 = 0.97$;$P<0.05$).

Conclusion

Iterative reconstruction is a valuable technique for routine brain CT imaging, allowing detection of pathology at reduced dose. Data confirms reduced noise and improved CNR of pathology with increasing levels of IR blends. However, subjective assessment suggests that this may not be the only important factor in radiologic interpretation, with radiologist preference for moderate levels of IR, although variable between individuals. This may reflect the smoother, more uniform appearances of higher IR levels.

Relationship between Brain-Derived Neurotrophic Factor Gene Polymorphism and Brain Volume in Major Depressive Disorder: Voxel-Based Morphology Analysis of Brain MR Imaging

Ide, S.[1]·Kakeda, S.[1]·Watanabe, K.[1]·Yoshimura, R.[1]·Abe, O.[2]·Nakamura, J.[1]·Korogi, Y.[1]
[1]University of Occupational and Environmental Health, Kitakyushu, JAPAN, [2]Nihon University School of Medicine, Tokyo, JAPAN.

Purpose
A brain-derived neurotrophic factor (BDNF) potentiates release of dopamine, response to emotionally salient environmental stimuli. The polymorphism of the BDNF gene Val66Met confers genetic susceptibility to a range of major depressive disorder (MDD), and has been found to impact brain morphology. The presence of a Met66 substitution leads to decreased secretion of BDNF at the synapse, and it follows that Met66 allele carriers (either Met-carriers) should have smaller brain volumes than Val/Val homozygotes (Val/Val-carriers). To our knowledge, however, no report has demonstrated that there is a significant volumetric difference in the gray matter between the Val/Val-carriers and either Met-carriers in MDD patients. We investigated the relationship between the brain volume and polymorphism of the BDNF gene in MDD using a voxel-based morphometry (VBM) analysis of brain MRI data.
Materials & Methods
Thirty patients with MDD (17 males, 13 females; mean age 44.9 ± 13.0 years; age range 22-67 years) and age- and sex-matched 30 healthy subjects (17 males, 13 females; mean age 43.7 ± 12.6 years; age range 20-65 years) were divided into the following four groups according to the BDNF gene polymorphism; MDD patients with either Met-carriers (n = 25), MDD patients with Val/Val-carriers (n = 5), healthy subjects with either Met-carriers (n = 20), and healthy subjects with Val/Val-carriers (n = 10). The MR imaging data were obtained with all cases using 3D SPGR (a three-dimensional fast spoiled gradient recalled acquisition with steady state) at 3T MRI. Image processing for VBM was conducted using SPM8 (Statistical Parametric Mapping 8). The DARTEL (Diffeomorphic Anatomical Registration Through Exponential Lie Algebra) toolbox was used in a high-dimensional normalization protocol. The VBM was used to analyze the significance for between-group differences of MRI data.
Results
The comparison between MDD patients and healthy subjects demonstrated the significant genotype-diagnosis interaction on GM volume in the left middle frontal gyrus (composition of prefrontal cortex). Furthermore, in MDD patients, the volume of the left middle frontal gyrus also was significantly smaller for the Met-carriers than for the Val/Val-carriers (P<.05) (Figure).

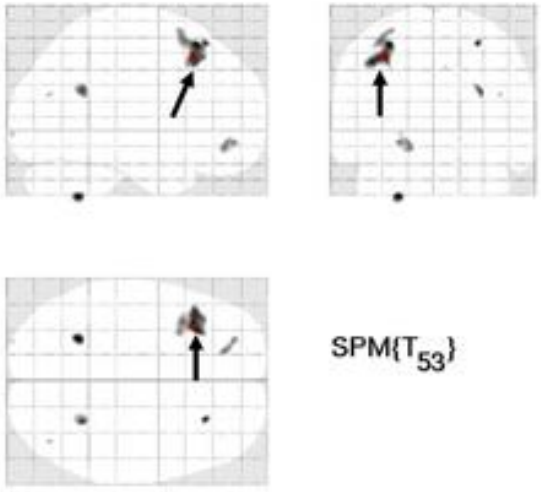

Figure: The region (arrows) shows a significant GM volume decrease in the MDD patients with Met-carriers in comparison to those with Val/Val-carriers (p<0.05).
Conclusion
The polymorphism of BDNF gene was associated with atrophy of the prefrontal cortex in MDD patients, which may relate to manifestation of MDD.

Comparison of Cerebral Blood Flow on Perfusion MR Imaging by Using Arterial Spin Labeling and Dynamic Susceptibility Contrast in Brain Tumors

Tsuchiya, K.·Ohara, A.·Gomyo, M.·Tateishi, H.·Nitatori, T.
Kyorin University
Tokyo, JAPAN.

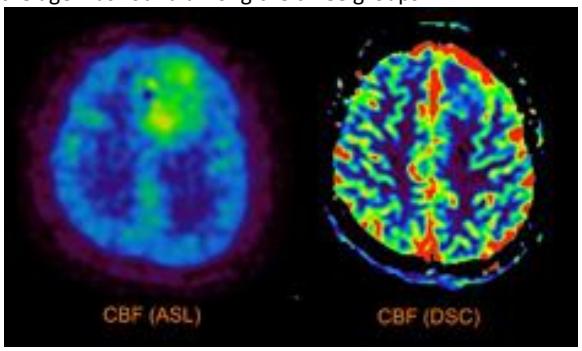
Purpose
Arterial spin labeling (ASL) is a technique that can visualize cerebral blood flow (CBF) by electromagnetically labeling arterial flow. To assess the feasibility of ASL perfusion in the diagnosis of brain tumors, we compared CBF by using ASL and that by using dynamic susceptibility contrast (DSC) imaging that has been an established technique.
Materials & Methods
We visually compared perfusion maps by the two methods in 17 cases (seven men and 10 women; age range, 21-76 years; mean, 54.2 years) of preoperative brain tumor. Their lesions included glioblastoma (six cases), metastasis (two cases), meningioma (two cases), primary central nervous system lymphoma (PCNSL, two cases), and others [anaplastic oligoastrocytoma (AOA), two cases; diffuse astrocytoma, oligodendroglioma, and choroid plexus papilloma, one case each]. Perfusion imaging by both ASL and DSC was performed on the same session using a 3T system. Arterial spin labeling was performed using a pulsed ASL sequence with scanning parameters as follows:

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

TR/TE/TI (labeling delay time)/FA, 6.0 ms/2.1 ms/220 ms/15 deg; FOV, 256 × 256 mm; imaging matrix, 64 × 64; section thickness, 6 mm; number of sections, 15; NEX, 4; acceleration factor, 2.0; and acquisition time, 3 min 24 sec. Dynamic susceptibility contrast perfusion MR imaging scans were acquired with a single-shot field-echo echo-planar imaging sequence (TR/TE/FA, 2000 ms/25 ms/90 deg; FOV, 240 × 240 mm; matrix, 128 × 96; section thickness, 5 mm; number of sections, 17; number of scans, 30; acquisition time, 1 min) in combination with a bolus injection of Gd-based contrast agent.

Results

In 11 of the 17 cases (average age, 56.9 years), CBF by the two methods were equivalent. In four cases (two cases of metastasis and each one case of glioblastoma and oligodendroglioma; average age, 52.5 years), CBF by ASL was less than that by DSC, while the former apparently was greater in two cases (each one case of PCNSL and AOA; average age, 53 years). No statistical difference in the age was found among the three groups.



Conclusion

Discrepancy often is found between CBF by ASL and that by DSC. This may be caused by difference in tumor hemodynamic characteristics and also be related to the labeling delay time in ASL.

Comparative Effectiveness of Unruptured Cerebral Aneurysm Therapies: Propensity Score Analysis of Clipping versus Coiling

McDonald, J. S.·McDonald, R. J.·Kallmes, D. F.·Lanzino, G.·Cloft, H. J.
Mayo Clinic
Rochester, MN.

Purpose

Endovascular therapy has increasingly become the most common treatment for unruptured cerebral aneurysms in the United States. We evaluated a national, multi-hospital database to examine recent utilization trends and compare peri-procedural outcomes between clipping and coiling treatments of unruptured aneurysms.

Materials & Methods

The Premier Perspective database was used to identify patients hospitalized between 2006-2011 for unruptured cerebral aneurysm who underwent clipping or coiling therapy. A logistic propensity score was generated for each patient using relevant patient, procedure, and hospital variables, representing the probability of receiving clipping. Covariate balance was assessed using conditional logistic regression. Following propensity score adjustment using 1:1 matching methods, the risk of in-hospital mortality and morbidity was compared between clipping and coiling cohorts.

Results

A total of 4899 unruptured aneurysm patients (1388 clipping, 3551 coiling) treated at 120 hospitals were identified. Following propensity score adjustment, clipping patients had a similar likelihood of in-hospital mortality [OR = 1.43 (95% CI 0.49-4.44), p =.47] but a significantly higher likelihood of unfavorable outcomes including discharge to long-term care [OR = 4.78 (95% CI 3.51-6.58), p<.0001], ischemic complications [OR = 3.42 (95% CI 2.39-4.99), p<.0001], hemorrhagic complications [OR = 2.16 (95% CI 1.33-3.57), p<.0001], postoperative neurologic complications [OR = 3.39 (95% CI 2.25-5.22), p<.0001], and ventriculostomy [OR = 2.10 (95% CI 1.01-4.61), p = .0320] compared to coiling patients.

Conclusion

Among patients treated for unruptured intracranial aneurysms in a large sample of hospitals in the United States, clipping was associated with similar mortality risk but significantly higher peri-procedural morbidity risk compared to coiling.

Comparative Effectiveness of Ruptured Cerebral Aneurysm Therapies: Propensity Score Analysis of Clipping versus Coiling

McDonald, R. J.·McDonald, J. S.·Kallmes, D. F.·Lanzino, G.·Cloft, H. J.
Mayo Clinic
Rochester, MN.

Purpose

The relative merits of treating ruptured aneurysms with clipping versus coiling continue to be a topic of debate. We evaluated a national, multihospital patient database to examine recent trends in ruptured aneurysm therapies and to compare peri-procedural outcomes between clipping and coiling treatments.

Materials & Methods

The Premier Perspective database was used to identify patients hospitalized between 2006 and 2011 for ruptured aneurysm who underwent clipping or coiling therapy. A

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

propensity score model, representing the probability of receiving clipping, was generated for each patient using relevant patient and hospital variables. Covariate balance was assessed using conditional logistic regression. Following greedy-type matching of the propensity score, the risk of in-hospital mortality and morbidity was compared between clipping and coiling cohorts.
Results
A total of 5229 ruptured aneurysm patients (1228 clipping, 4001 coiling) treated at 125 hospitals were identified. Clipping therapy frequency decreased from 27% in 2006 to 21% in 2011. Following propensity score adjustment, in-hospital mortality risk was similar between groups [OR = 0.94 (95% CI 0.73-1.21) p = .62]. However, unfavorable outcomes were more common in following clipping compared to coiling, including discharge to long-term care [OR = 1.32 (95% CI 1.12-1.56) p = .0006], ischemic complications [OR = 1.51 (95% CI 1.24-1.83); p = .0009], neurologic complications [OR = 1.64 (95% CI 1.18-2.27); p = .0018], and other surgical complications [OR = 1.55 (95% CI 1.05-2.33); p = .0240].
Conclusion
This study of a database of multiple hospitals in the United States demonstrates that clipping of ruptured cerebral aneurysms resulted in greater adjusted morbidity compared to coiling.

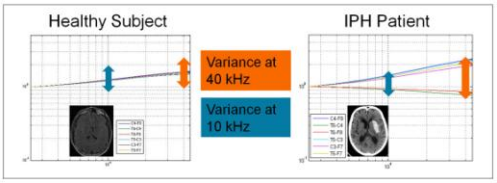
An "EKG for the Brain": Electrical Impedance Spectroscopy for Brain Injury

Kamalian, S.·Rosenthal, E. S.·Bonmassar, G.·Borgie, R. C.·Schwamm, L. H.·Lev, M. H.
Massachusetts General Hospital
Boston, MA.

Purpose
Electrical impedance spectroscopy (EIS) is novel, portable, easy-to-implement device that aims to provide rapid, affordable point-of-care detection, assessment, and monitoring of acute brain injury. An adaptation of "passive" electroencephalography (EEG), EIS relies on noninvasive measurement and modeling of the conduction of minute electrical currents applied transcranially across a spectrum of frequencies. Our purpose was to test the feasibility of EIS to distinguish the impedance differences between normal subjects and brain injury attributable to acute/subacute intracranial hemorrhage or subacute ischemic stroke.
Materials & Methods
We performed a prospective, observational, proof-of-principle study of 15 patients admitted to our Neurosciences Intensive Care Unit for ischemic stroke or intracranial hemorrhage compared to four healthy volunteers. Subjects underwent five minutes of EIS recordings. Electrical impedance spectroscopy device delivers small white-noise current through a pair of stimulation electrodes. Voltage is recorded across three bilaterally symmetric pairs according to 10-20 standard EEG system. The transfer function between the white-noise current input and the recorded voltages was estimated for each recording electrode. Log-log plot of the estimated impedance difference of bipolar ipsilateral neighbor electrodes plotted across the 100Hz to100kHz frequency, which is normalized at 100Hz (Figure 1). The impedance variances, among referenced channels, were recorded at 10 and 40 kHz.
Results
Comparing patients with healthy controls (Figure 1): intrasubject variance among all channels (bipolar to ipsilateral neighboring electrodes) for impedance at 10 kHz, were significantly different (p = 0.02) and area under the curve of ROC analysis was 85% with 80% sensitivity, 100% specificity at 10 kHz (p = 0.0002). Intrasubject variance among all channels for impedance at 40 kHz also were significantly different (p = 0.03) and area under the curve was 87% with 80% sensitivity, 100% specificity at 40 kHz (p<0.0001).



Conclusion
Electrical impedance spectroscopy device is a promising, noninvasive, portable imaging modality that has the potential to be applied in clinical practice to triage patients with acute brain injuries in the battlefield, sportfield and ambulance. Moreover EIS has the potential to be utilized as a brain-monitoring device in Neuro ICU patients to detect new changes in the intracranial pathology.

Accuracy and Interobserver Reliability of CT Angiography Spot Sign Detection in Acute Intracerebral Hemorrhage by Physician Specialty and Training Level: A Prospective Multicenter Study

Huynh, T. J.[1]·Gladstone, D. J.[1]·Flaherty, M. L.[2]·Broderick, J. P.[2]·Demchuk, A. M.[3]·Dowlatshahi, D.[4]·Meretoja, A.[5]·Davis, S. M.[5]·Mitchell, P.[5]·Tomlinson, G. A.[1]·Chia, T. L.[1]·Symons, S. P.[1]·Aviv, R. I.[1]
[1]University of Toronto, Toronto, ON, CANADA, [2]University of Cincinnati, Cincinnati, OH, [3]University of Calgary, Calgary, AB, CANADA, [4]University of Ottawa, Ottawa, ON, CANADA, [5]Royal Melbourne Hospital, Melbourne, AUSTRALIA.

Purpose
Rapid, accurate, and reliable identification of the CT

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

angiography (CTA) spot sign is required to identify patients with intracerebral hemorrhage (ICH) for potential acute hemostatic therapy in clinical trials. We sought to assess the accuracy and interobserver agreement for spot sign identification among neurologists, emergency physicians and neuroradiologists stratified by clinical training level.
Materials & Methods
A total of 120 physicians (48 staff neurologists, 58 neurology fellows; four emergency physicians, three emergency fellows; five staff neuroradiologists, two neuroradiology fellows) underwent web-based CTA spot sign identification training and imaging certification needed to enroll patients in three clinical trials targeting spot-positive ICH patients for hemostatic therapy (STOP-IT, SPOTLIGHT, STOP-AUST). As part of the certification process, 10 ICH cases (five spot-positive, five spot-negative including two spot mimics) were presented to physicians to assess for spot sign presence, spot number, and presence of spot mimic. Representative cases were chosen from our institutional ICH database and true spot-positivity was determined by consensus by three experienced staff neuroradiologists not included in the analysis. Physician accuracy, sensitivity, specificity and time to spot identification were determined. Differences in accuracy, sensitivity, and specificity by clinical specialty and training level were compared with Kruskal-Wallis and Wilcoxon rank sum tests. Interobserver agreement was examined by specialty and training level with the Fleiss multirater kappa statistic.
Results
For spot-positive cases, median (range) spot number, maximum axial spot size, and spot attenuation was one (1-12), four (3.1 - 10.7) mm, and 203 (201 - 496) HU, respectively. Mean (SD) overall accuracy was 87 ± 11% and was similar among neurologists, emergency physicians, and neuroradiologists (87 ± 11%, 87 ± 8%, and 93 ± 8% respectively; p = 0.192). Sensitivity and specificity also was similar among specialties (p = 0.353 and 0.358 respectively). Overall sensitivity for spot detection was reduced compared to specificity (79 ± 19% and 95 ± 11% respectively, p<0.001). Accuracy of staff compared to fellows demonstrated no significant difference (p = 0.125). Overall agreement among staff was substantial (k = 0.63, 95% CI 0.61 - 0.65) and was highest among neuroradiologists (k = 0.79, 95% CI 0.60 - 0.99) compared to neurologists (k = 0.59, 95% CI 0.58 - 0.60) and emergency physicians (k = 0.59, 95% CI 0.46 - 0.73). Median time to spot identification was 2.0 minutes (interquartile range, 1.4 - 3.2 minutes) and was similar among specialties (p = 0.348). True spot signs that were incorrectly classified were most commonly interpreted as spot mimics (p<0.001). When true spots were correctly identified, 80% of responses correctly identified presence of single or multiple spots.
Conclusion
Accuracy for spot identification is high across all specialties with substantial interobserver reliability. High accuracy and agreement is critical for recruitment into ongoing clinical studies.

Community Hospital Experience with Utility of CT Angiography in Acute Intraparenchymal Hemorrhage

Metting, S. W.·Alexander, M. D.·Pandit, R. P.·Patel, M. R.
Santa Clara Valley Medical Center
San Jose, CA.

Purpose
Intraparenchymal hemorrhage (IPH) can result from various etiologies, many of which can be diagnosed by noninvasive CT angiography. Given the potentially grave consequences of such hemorrhage, particularly if progression of primary hemorrhage or re-hemorrhage occur, exclusion of underlying pathology is warranted. Although computed tomographic angiography (CTA) is being increasing utilized in the assessment of IPH, often in an emergent setting, the utility, value, and optimal timing of the study remains to be evaluated.
Materials & Methods
A retrospective analysis identified all CTAs performed at a high volume community hospital from January 2001 through November 2012 performed for IPH based on review of the radiology PACS report. These were cross-referenced against unenhanced CTs with demonstrated IPH. Demographic data, presence of trauma, and imaging results were evaluated including presence of hemorrhage and underlying lesions. Analysis of patients with CTA performed for IPH was conducted to investigate differences in rates and types of positive angiographic findings when comparing between certain variables like age, sex, and associated trauma.
Results
One thousand four hundred ninety-one CTAs were performed for 1344 patients during the study period, of which analysis was completed for 549 patients at the time of this submission. Of the analyzed cases, IPH was present in 63 (11.5%) cases. Thirty-seven (58.7%) of these patients were men. Among these patients, trauma had occurred in 26 (41.3%) patients. Mean age was statistically significantly younger among patients with trauma compared to those without (41.5 years versus 53.3 years, respectively, p = 0.017). Abnormality in addition to intracranial hemorrhage was identified in eight (30.8%) patients with trauma and 13 (35.1%) patients without (p = 0.722). Rates of underlying aneurysms in the setting of IPH were higher in the atraumatic cohort compared to patients with trauma (24% versus 3.8%, respectively, p = 0.07). Other pathologic processes identified included arteriovenous malformation, vessel injury with active extravasation, dissection, vasospasm, vessel occlusion, and venous sinus thrombosis. No statistically significant

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

differences were identified between groups with relation to these other processes.

Conclusion

Intraparenchymal hemorrhage may result from underlying causative processes that must be identified to properly guide treatment. CT angiographs play a role for detection of such pathology, yet little large-scale evaluation of these techniques has been performed to date. Eleven and one-half percent of CTAs performed in the current series demonstrated IPH, and one in three patients with IPH had identifiable underlying pathology. Multiple types of pathology were identified, with aneurysms being most common. Aneurysms were much more likely to occur in people without concomitant trauma than those with. Patients with IPH who have experienced trauma tend to be younger than those who have not. Further analysis of the utility of CTA in the setting of IPH is warranted, particularly with respect to changes in management and affects on outcomes.

Role of Low-Dose Nonenhanced Brain CT in the Neurosurgical and Neurologic Intensive Care Unit

Hoch, M.[1]·Sethi, V.[2]·Shah, P.[1]·O'Connor, E.[1]·Hershey, B.[1]·Ali, S.[1]·Dass, C.[1]
[1]Temple University Hospital, Philadelphia, PA, [2]Temple University Medical School, Philadelphia, PA.

Purpose

To identify a patient population subject to serial short-term follow-up CT evaluation that may benefit from low dose CT examination. Most neurosurgical/neurologic intensive care unit (NICU) patients undergo multiple serial CT scans during a single hospitalization. After the initial routine scan, we explored if low dose follow-up scans could effectively evaluate NICU patients without sacrificing diagnostic accuracy.

Materials & Methods

Following IRB approval, a retrospective chart review was performed identifying 19 NICU patients (ages 18-73 years, mean 49 years) who had three axial nonenhanced brain CT examinations within a span of 72 hours in the following sequence: initial routine dose, followed by low dose, and finally routine dose. Included studies showed a persistent finding on the initial and final scans. From these routine and low dose scans, 59 unique pairs of comparative individual slices were selected (Figure 1). Two board-certified neuroradiologists, each blinded to the scan parameters and patient information evaluated the selected slices. The readers were asked if each image was diagnostically acceptable for interpretation and to note the presence or absence of the following findings: infarction, hemorrhage, herniation, and catheter location. All CT scans were performed on Siemens Sensation 16- or 64-slice machines. Routine scans were acquired with mAs ≥ 310 and collimation of 1.2 - 1.5 mm, while low-dose scans had mAs ≤ 280 and collimation of 5 mm. All other imaging parameters including 120 kVp were kept constant. Regions of interest placed over gray and white matter were obtained from each slice to calculate contrast-to-noise ratios (CNR).

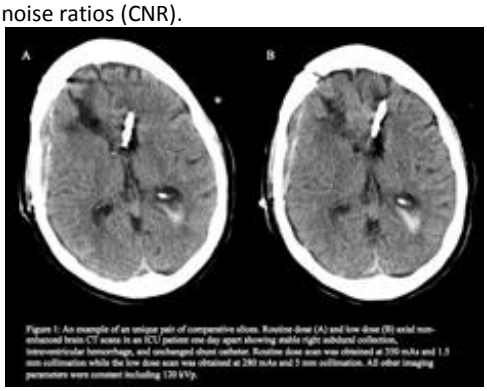

Figure 1: An example of an unique pair of comparative slices. Routine dose (A) and low dose (B) axial non-enhanced brain CT scans in an ICU patient one day apart showing stable right subdural collection, intraventricular hemorrhage, and unchanged ghost catheter. Routine dose scan was obtained at 310 mAs and 1.5 mm collimation while the low dose scan was obtained at 280 mAs and 5 mm collimation. All other imaging parameters were constant including 120 kVp.

Results

There was very high (95.3%) interobserver agreement in identifying pertinent findings on routine and low dose brain CT examinations among the sampled NICU patients (Table 1). Compared to routine dose, low dose CT imaging delivered a 26.07% reduction in average CTDIvol. Despite an average CNR reduction of 29.23%, low-dose imaging provided equal if not better diagnostic accuracy.

Table 1: Findings Made on Routine vs Low Dose CT

	Routine Dose			Low Dose		
	Reader 1	Reader 2	Concordance	Reader 1	Reader 2	Concordance
Venticular Catheter/ICP Monitor Location	10	10	100%	10	10	100%
Midline Herniation	17	20	85%	19	19	100%
Extracranial Herniation	4	4	100%	4	3	75%
Infarction	15	16	94%	17	17	100%
Intra-axial Hemorrhage	30	31	97%	31	30	97%
Extra-axial Hemorrhage	32	32	100%	38	37	97%

Conclusion

Low-dose brain CT is diagnostically acceptable when applied to the adult NICU population, emphasizing the concept of ALARA (As Low As Reasonably Achievable). Further collaboration with referring clinicians may allow development of additional dose reduction protocols.

KEYWORDS: Radiation dose reduction, Protocols, ALARA

Improved Quality and Diagnostic Confidence Achieved by Use of Dose-Reduced Gadolinium Blood Pool Agents for Time-Resolved Intracranial MR Angiography

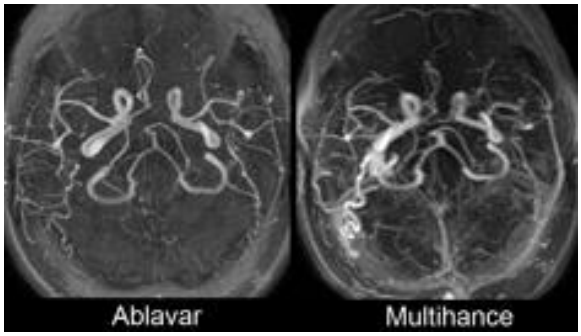
Dehkharghani, S.·Boddu, S. R.·Saindane, A.
Emory University Hospital
Atlanta, GA.

Purpose

Time-resolved MR angiographic (TR MRA) techniques

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

using bolus injection of paramagnetic contrast agents to shorten blood T1 have been employed to evaluate the intracranial vasculature. Standard contrast agents have limited blood pool residence times, thus the rationale for the development of highly protein bound blood-pool agents (BPA) with higher T1 relaxivity and longer intravascular residence, theoretically affording improved image quality with smaller administered doses. This study compares the diagnostic quality of the BPA gadofosveset trisodium (Ablavar) to a standard agent gadobenate dimeglumine (Multihance) for intracranial TR MRA.
Materials & Methods
One hundred datasets were acquired in patients with known or suspected cerebrovascular abnormalities on a clinical 1.5T GE system with time resolved imaging of contrast kinetics (TRICKS) using a standardized protocol. Patients were administered recommended, weight-based doses of Multihance at 0.1 mmol/kg or Ablavar at 0.03 mmol/kg. Two neuroradiologists blinded to the administered agent analyzed images in consensus as follows: Peak arterial and venous enhancement were identified from maximum intensity projections, noting the presence or absence of a nonvenous-contaminated arteriographic phase. Axial source data corresponding to peak arterial and venous phases subsequently were reviewed for quality of enhancement, with attention to six vascular segments: 1) cavernous/supraclinoid internal carotid arteries (ICA); 2) middle cerebral artery (MCA) M1 segment; 3) MCA M2 branches; 4) MCA M3 branches; 5) deep cerebral veins; and 6) dural venous sinuses. Images also were evaluated for artifact-related degradation.
Results
Fifty patients were present in both the Ablavar and Multihance groups. All datasets were complete and deemed satisfactory for assessment. No significant differences were found between agents in their generation of uncontaminated arteriograms. Datasets using the BPA Ablavar, at a lower dose of gadolinium, were rated to be of significantly greater diagnostic quality than Multihance across all interrogated arterial segments including: ICA (p=0.019), M1 (p=0.05), M2 (p=0.003), and M3(p<0.01). Datasets using Ablavar were rated as having significantly better enhancement of the deep venous structures (p=0.016), but not for dural venous sinuses. The frequency of artifacts did not differ significantly between agents. The figure demonstrates the improved quality in peak arterial enhancement using Ablavar in a patient scanned on separate occasions with both contrast agents.



Conclusion
The BPA Ablavar provides superior evaluation of the smaller intracranial arterial and venous structures in TR MRA than Multihance, at a substantially lower dose of gadolinium. This is attributed to the higher relaxivity and pharmacokinetic advantages of BPAs for TR MRA.

Usefulness of Gadolinium-Enhanced Fast Fluid Attenuated Inversion Recovery MR Imaging in Patients with Head Injury

Park, S.[1,2]·Kim, S.[1]
[1]Boramae Medical Center, Seoul, KOREA, REPUBLIC OF, [2]Seoul National University College of Medicine, Seoul, KOREA, REPUBLIC OF.

Purpose
The purpose of this study was to investigate the clinical utility of gadolinium-enhanced fluid attenuated inversion recovery (FLAIR) magnetic resonance (MR) imaging of the brain in patients with head injury.
Materials & Methods
In 70 consecutive patients with head injury referred for gadolinium-enhanced fast fluid attenuated inversion recovery (FLAIR) MR imaging were performed before and after administration of gadopentetate dimeglumine (0.1 mmol per kilogram of body weight). Pre and postcontrast images were evaluated to determine the presence of abnormal contrast enhancement.
Results
Thirty-six of 70 studies showed dural enhancement on post FLAIR images. Diffuse dural enhancement of the whole brain was seen in 10 studies. Seventeen cases demonstrated localized dural enhancement in the location of abnormal localized enhancement of the dura mater correlated with the injured area. In nine studies, falx cerebri only was enhanced. Compared with postcontrast T1-weighted images, postcontrast FLAIR images showed more dural enhancement in 19 patients, an equal number in 10, and fewer lesions in six. Dural enhancement on postcontrast FLAIR images was statistically correlated with the existence of subarachnoid hemorrhage, subdural

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

hemorrhage, post-traumatic loss of consciousness and transient amnesia. (p = 0.005, 0.041, 0.000, 0.032)
Conclusion
Postcontrast FLAIR images well presents dural enhancement in patients with head injury. Moreover the presence of abnormal dural enhancement on postcontrast FLAIR images might imply considerable head injury. So, radiologists should pay more attention to detecting traumatic brain lesion such as small amount of subdural hemorrhage or subarachnoid hemorrhage in case abnormal dural enhancement is shown.

Outcome Prediction in Patients with Glioblastoma Multiforme Using Clinical Features, MR Imaging, and Genetic Biomarkers

Nicolasjilwan, M.[1]·Ying, H.[2]·Chunhua, Y.[2]·Meerzaman, D.[2]·Raghavan, P.[1]·Gutman, D.[3]·Huang, S.[3]·Holder, C.[3]·Chen, J.[4]·Freymann, J.[5]·Kirby, J.[5]·Jaffe, C.[6]
[1]University of Virginia, Charlottesville, VA, [2]National Cancer Institute, Bethesda, MD, [3]Emory University Hospital, Atlanta, GA, [4]University of California San Diego, San Diego, CA, [5]SAIC-Frederick, Inc., Frederick, MD, [6]Boston University School of Medicine, Boston, MA.

Purpose
Recent advances in glioblastoma treatment have geared current research into identification of different categories of biomarkers that can predict patient outcome, and consequently may impact therapeutic decisions through the selection of more aggressive therapies for the tumors with the worse prognosis. The impact of clinical factors on patient outcome and the correlation between MR imaging features of GBM and survival have been reported previously in the literature. Similarly, the association between genomic biomarkers and patient outcome has received growing attention, in particular with the recent introduction of antiangiogenetic drugs. The purpose of our study was to incorporate clinical factors, imaging biomarkers, and tumor gene expression into a statistical model that would potentially constitute a more robust predictor of patient survival than either individual data.
Materials & Methods
The study was conducted as part of the TCGA effort supported by the National Cancer Institute (http://www.cancergenome.nih.gov/). MRI images of 70 GBM patients were reviewed by six neuroradiologists using the VASARI scoring system. The patients' clinical and genetic data were available through the TCGA website. Patient outcome was measured in terms of survival time. The correlation between different categories of biomarkers and survival was evaluated using Cox regression models.
Results
On multivariate analysis, the only features that correlated significantly to survival were: 1) in terms of clinical factors: chemotherapy; 2) in terms of imaging: proportion of tumor enhancing, and 3) in terms of genetics: expression of the gene HRAS. The incremental addition of these three biomarkers into Cox regression models results in an incremental increase in the prediction strength in terms of survival, with the model including clinical, imaging and genetic variables having the highest predictive accuracy.
Conclusion
A combination of clinical factors, VASARI imaging features, and tumor genes predicts survival of patients with GBM. This information may be valuable, as more treatments become available, in directing a more individually tailored therapeutic approach.

Sub-Pial Hemorrhage: Is This an Unusual but Distinct Distribution of Intracranial Hemorrhage?

Matheus, G.·Enterkin, J.·Bartynski, W.
Medical University of South Carolina
Charleston, SC.

Purpose
To demonstrate representative cases of superficial parenchymal hemorrhage with unique imaging features consistent with a sub-pial distribution. Based on these cases we will further discuss the anatomical and physiologic characteristics of the axial and extra-axial spaces with emphasis upon the sub-pial region through both a descriptive and pictorial approach.
Materials & Methods
Five patients were identified with CT and MR imaging demonstrating intracranial hemorrhage with an unusual

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

distribution suggestive of a sub-pial location (4 adults and 1 infant). Clinical context included: trauma [three patients; nonenhanced head CT (NEHCT)], postaneurysm rupture (one patient; NEHCT), and one 9-month-old infant with a parietal hemorrhage of unclear etiology (NEHCT and MRI). Review of the current literature regarding imaging findings, epidemiology, potential consequences, and the anatomy of sub-pial hemorrhage also was conducted.
Results
All of the patients demonstrated the unique imaging pattern including: 1) hemorrhage localized along the brain surface, 2) focal and distinct mass effect upon the adjacent cortical gyri and 3) associated focal sulcal expansion. Hemorrhage locations included frontal lobe, temporal lobe and parietal region. Surface hemorrhage was not free and/or mobile in the subarachnoid space. Confusion with subdural hemorrhage was common. In two of the cases the displaced cortex showed focal hypodensity on NEHCT and with MR imaging demonstrating abnormal signal of the displaced cortex on both T1- and T2-weighted images with associated reduced diffusion. Literature review demonstrates a few cases of localized leptomeningeal/superficial parenchymal distribution intracranial hemorrhage, which has been described in both adults and term newborns. Multiple speculative etiologies are proposed without a definitive consensus for the atypical distribution of the hemorrhage. All of the cases described in the literature with longitudinal follow-up imaging resulted in subsequent encephalomalacia. The sub-pial region has been shown anatomically to represent a poorly distensible space that resides between the pia mater and glia limitans on the brain surface. Arteries and veins cross this space which also contains bundles of collagen fibers extending into the trabecula of the subarachnoid space.
Conclusion
The sub-pial space is a distinct space that can be affected by intracranial hemorrhage. Localized hematomas may form in this space with unique imaging features. These hemorrhages may be associated with adjacent brain parenchymal injury - either primary (i.e., from contusion) or secondary (related to decreased distensibility of this space with resultant compression and/or sequela of direct blood product toxicity to the glia limitans and cortex). A more complete understanding of this atypical hemorrhagic pattern may in turn affect the approach to clinical management.

Incidence of Petrous Apex Cephalocele in Patients with Empty Sella

Jamjoom, D. Z.·Alorainy, I. A.
College of Medicine, King Saud University
Riyadh, SAUDI ARABIA.

Purpose
Petrous apex cephalocele (PAC) is a rare lesion that has been linked to empty sella in several case reports. The primary aim of this study is to document the incidence of PAC in patients with empty sella and examine the correlation between the size of these two lesions, in an attempt to better understand the underlying etiology of PAC. The secondary aim of this study is to document the imaging characteristics of PAC in a large cohort.
Materials & Methods
We found 275 patients with the terms "empty sella" in our radiology report database for the period from January 2005 to December 2011. A total of 214 patients met our inclusion criteria. Retrospective analysis of patients' head CT and/or MRI was performed by two radiologists independently.
Results
Petrous apex cephalocele was found in 33 (15.4%) patients (age range 17 to74 years), and 32 of these were females. Bilateral PAC was more common and seen in 25 patients. There was a statistically significant correlation between the size of empty sella and PAC on the left side. On imaging, all PAC lesions were continuous with the posterolateral aspect of Meckel's cave causing smooth erosion on the anterior part the petrous apex. Lesions followed fluid signal on both CT and MRI.
Conclusion
Petrous apex cephalocele is seen in 15% of patients with empty sella, and in the majority it is bilateral.

Normal Variability in the Morphology of the Lumbar Disk Annuli and their Adjacent Endplates

Engel, C. W.·Martinez, C. R.·Ford, J. M.·Davy-Jow, S. L.·Decker, S. J.
University of South Florida Morsani College of Medicine
Tampa, FL.

Purpose
Variation in the morphology of the posterior margin of the lumbar annuli has not been thoroughly described. Our aim was to determine the normal shape of the posterior lumbar disk annuli and their adjacent endplates through the CT evaluation of normal lumbar spines in a select population of young adults.
Materials & Methods
Two reviewers retrospectively selected 60 CT scans of the

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

abdomen/pelvis (average age = 27.25 years) from a large pool of young adults who presented to an outpatient diagnostic center for evaluation of possible abdominal and/or pelvic pathology. Exclusion criteria included congenital spinal variations/anomalies, scoliosis, prior trauma, degenerative disk or facet disease, disk protrusion, and spondylolisthesis. Three-dimensional models of the lumbar vertebrae and disks were rendered from original raw data, and the curvatures of the posterior margins of the disks and endplates were measured using 3D modeling software.

Results

With positive values reflecting anterior concavity and negative values reflecting posterior convexity, posterior disk curvature was 0.53 ± 0.19 cm^{-1} at L1L2, 0.38 ± 0.16 cm^{-1} at L2L3, 0.30 ± 0.18 cm^{-1} at L3L4, 0.07 ± 0.20 cm^{-1} at L4L5, and -0.20 ± 0.22 cm^{-1} at L5S1 (mean ± 1 SD). The superior endplate curvatures were 0.56 ± 0.14 cm^{-1} at L1L2, 0.42 ± 0.18 cm^{-1} at L2L3, 0.26 ± 0.17 cm^{-1} at L3L4, 0.02 ± 0.17 cm^{-1} at L4L5, and -0.17 ± 0.16 cm^{-1} at L5S1. The inferior endplate curvatures were 0.64 ± 0.18 cm^{-1} at L1L2, 0.50 ± 0.19 cm^{-1} at L2L3, 0.40 ± 0.18 cm^{-1} at L3L4, 0.17 ± 0.20 cm^{-1} at L4L5, and -0.02 ± 0.28 cm^{-1} at L5S1.

Conclusion

There is a normal variation in the shape of the posterior lumbar disk annuli as well as their adjacent endplates. This variation is subtle, with decreasing anterior concavity from L1L2 to L5S1 that usually results in posterior convexity at L5S1 and often at L4L5. The understanding of this normal variation in lumbar disk shape is important in order to avoid a false positive diagnosis of a disk bulge, particularly at L4L5 and L5S1.

Acute Cerebral Edema in CT Negative Patients with Traumatic Head Injury

Butman, J. A.[1,2]·Pham, D. L.[2]·Knutson, A.[2]·Latour, L. L.[3]
[1]The Clinical Center of the NIH, Bethesda, MD, [2]Center for Neuroscience and Regenerative Medicine, Bethesda, MD, [3]National Institute of Neurological Disorders and Stroke, Bethesda, MD.

Purpose

To report diffuse acute cerebral edema as a common consequence of traumatic head injury (THI) in patients with negative head CT.

Materials & Methods

Subjects enrolled in the THINC (Traumatic Head Injury Neuroimaging Classification) study were included with i) negative CT on admission, ii) acute MRI 5% was used to classify individuals as “positive” for acute cerebral edema and the association between edema and MR+ was tested using Fisher’s exact test. <0.05 was considered significant.

Results

Seventy-four subjects met criteria. Overall, ventricles increased in size between the two time points (dV = 2.3%, p<0.0001). Subjects found to be MR+ (n = 41) had a larger dV as compared to those were MR- (3.2% vs 1.1%, p = 0.02). There were 12 of 41 (28%) MR+ subjects classified as having acute edema using the 5% threshold in comparison to 3 of 33 (9%) of MR- subjects, p = 0.04.

Conclusion

Diffuse cerebral edema is a known consequence of THI, but is generally not possible to diagnose acutely unless severe. In this study, we identify a relatively rapid and significant decrease in brain volume between MRI scans performed over the first week, in THI patients with a negative CT scan. We propose that this change is due to resolution of the acute edema induced by the THI, and not due to volume loss, as atrophy would not be expected in this time frame. Cerebral edema was more prevalent and of a higher degree in MR+ patients as compared with MR- patients. Furthermore, we found a subgroup of MR- patients with changes in volume strongly suggestive of acute edema, despite otherwise normal imaging. The clinical implications of this finding remain to be elucidated. Methods to detect diffuse edema at a single time need to be developed.

KEYWORDS: Traumatic brain injury, Diffuse axonal injury

eP-106

Diagnostic Yield of Imaging Evaluations for Suspected Horner’s Syndrome

Delfyett, W. T.·Hein, A.·Chang Sen, L.·Rath, T. J.·Yu, J.
University of Pittsburgh Medical Center Presbyterian-Shadyside
Pittsburgh, PA.

Purpose

Horner's syndrome (ptosis, miosis, anhidrosis) results from a lesion involving the well defined oculosympathetic pathway. Suggested imaging work-up algorithms have been reported in the literature for suspected lesions at each level of the oculosympathetic pathway. However, the radiographic evaluation of suspected Horner's syndrome frequently is negative. The purpose of this study is to evaluate the diagnostic yield of the radiographic workup of suspected Horner's syndrome at adult UPMC facilities and to identify clinical characteristics of patients referred for imaging evaluation.

Materials & Methods

An IRB-approved retrospective search of the electronic medical record was performed for all adult UPMC facilities between 01/01/06 and 08/25/11, for keywords; Horner's or oculosympathetic palsy as a provided indication for imaging. The records of the clinical exam which prompted the imaging evaluation were reviewed by an ophthalmology fellow specifically for documented ptosis, miosis, anhidrosis, clinical presentation, and use of eye-drop testing. All radiographic studies were reviewed in a blinded fashion by a CAQ-certified neuroradiologist.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Studies were categorized as (1) negative, (2) lesion probably related to Horner's syndrome, and (3) lesion definitely causing Horner's syndrome. Categories two and three are considered positive in determining diagnostic yield.
Results
Retrospective medical record search yielded 155 patient evaluations for one or more of the keywords. These constituted 309 exams as determined by CPT codes. Services who provided patient referral were ophthalmology 30%, neurology 24%, internal medicine/primary care 21%, emergency medicine 14%, otolaryngology 2%, surgery 1%, neurosurgery <1%, 7% referring specialty was unclear. In 17 patients (10%) an overlap in symptoms was found and the imaging evaluation was not performed for a clinical Horner's syndrome. Clinical records were unavailable for 60 patients. Upon review of all imaging studies, 21 patient evaluations (14%) were deemed positive. For the subset in which clinical records were available, there were 18 positive cases (19%). Presenting symptoms included ptosis (73%), miosis (71%), and mnhidrosis (6%), ptosis and miosis (52%), and (4%) had ptosis, miosis and anhidrosis. Twenty-five patients (16%) had documented pharmacologic eye-drop testing. Positive radiographic evaluations included; eight carotid dissections, two carotid aneurysms, two lung adenocarcinomas, two midbrain strokes, one lung apex and chest wall invasive aspergillosis, two soft tissue abnormalities of the neck, two skull base lesions and one cervical cord metastasis.
Conclusion
Overall radiographic positive yield in the radiographic evaluation of Horner's syndrome at adult UPMC facilities was 14% for the study period. The ordered imaging workups were found to be heterogeneous across referring specialties. The low number of patients that met all components of Horner's syndrome (4%) suggests that partial Horner's syndromes may be very common or that many patients may be labeled "Horner's" who rather display an overlap in symptoms. There are acute clinical scenarios and known medical conditions which will guide the evaluation of Horner's syndrome aimed at excluding acutely life-threatening conditions such as vascular dissections. However, in an environment of increased utilization review and pre-approval processes, there may be a potential expanded role for relatively inexpensive pharmacologic eye-drop testing in more chronic patients in order to tailor imaging evaluations.

Neurographic Imaging with a Molecular Probe

Schellingerhout, D.·Bredow, S.·Le Roux, L.
M. D. Anderson Cancer Center
Houston, TX.

Purpose
To develop an agent for imaging retrograde axonal transport in nerve tissues based on the optical labeling of a nontoxic fragment of tetanus toxin.
Materials & Methods
A His-tagged recombinant tetanus toxin fragment C (TTc) was produced in E.coli, purified, and labeled with Alexa fluorophors for optical imaging studies. Gel electrophoresis (SDS-PAGE) and quantitative immunodetection studies were performed. Cell uptake studies were performed to assess in vitro efficacy. Labeled TTc was injected into the calf muscles of C57bl and Balb/C mice, and Wistar rats, and imaging performed with the IVIS 200 (Xenogen). In situ validation was performed with laser scanning confocal microscope FV 1000 (Olympus) utilizing intact glycerol mounted samples, and cryo-sections.
Results
Gel electrophoresis and quantitative immunodetection indicated that the integrity and immune reactivity of the protein was preserved after labeling. Cell uptake assays indicated robust uptake in differentiated PC12 cells. In vivo optical imaging demonstrated the uptake of TTc-Alexa in the sciatic nerve and spinal cord. Progressive uptake and transport of the agent could be seen along the course of the sciatic nerve and spinal cord. Confocal microscopy studies on intact excised nerve segments and cryosections confirmed the compound uptake in nerve fascicles of the sciatic nerve. Axonal nerve uptake and superficial lymphatic uptake were clearly distinguishable, and transport was shown to be nerve-specific. Immunohistochemistry on cord sections demonstrated the presence of the agent in spinal cord neurons.
Conclusion
Fluorescently labeled TTc is taken up into motor nerve endings after intramuscular injection, and is retrogradely transported in nerve axons. This process can be demonstrated with noninvasive in vivo imaging, and allows nerve anatomy and function to be studied.

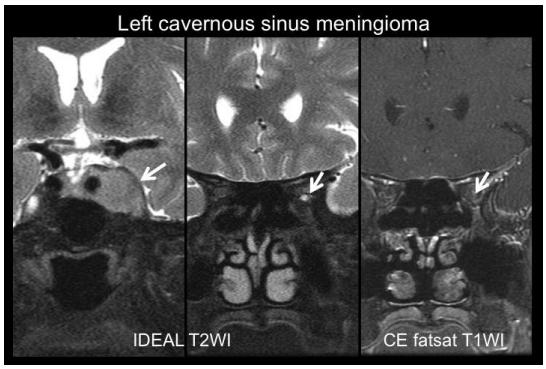
IDEAL T2-Weighted Imaging Assessment of Oculomotor Nerve Impairment

Koike, H.[1]·Morikawa, M.[1]·Enokizono, M.[1]·Uetani, M.[1]·Nakashima, H.[1]·Motomura, M.[1]·Ideguchi, R.[2]
[1]Nagasaki University School of Medicine, Nagasaki, JAPAN, [2]Nagasaki Municipal Hospital, Nagasaki, JAPAN.

Purpose
Several studies have reported usefulness of MRI in diagnosis of disease presenting with oculomotor nerve (CN3) palsy. But few studies have documented pathologic characteristics of CN3 on MRI. Iterative decomposition of water and fat with echo asymmetric and least-squares estimation (IDEAL) has been shown to effectively suppress fat, even in the presence of magnetic field inhomogeneity. Therefore, IDEAL sequence is expected to improve visualization of CN3 in cavernous sinus and apex of orbit. Our object is to evaluate the utility of IDEAL T2-weighted image (T2WI) for detection of oculomotor pathology, and for differentiating CN3 disease from other related disease.
Materials & Methods
We retrospectively examined 17 patients presenting with CN3 palsy or similar symptoms (five men, 12 women; age range: 23 - 88 years) between 2010 and 2012 at our hospital. Seven of the 17 patients had inflammatory disease (six oculomotor neuritis, and one radiation injury), six patients had compression of CN3 (three aneurysms, two after transvenous embolization for carotid cavernous sinus fistula, and one meningioma) and four patients had muscular disease (two myasthenia gravis, one Basedow's disease, one idiopathic external ophthalmoplegia). All MR examinations were performed using a 3T MR scanner with an 8-channel head coil. Coronal IDEAL T2WI was performed with the following parameter: TR/TE = 3400-4000/82-88 ms, FOV = 12 × 12 cm, matrix = 320 × 160, thickness = 2.5 mm). Regions of interest (ROI) of CN3, genu of corpus callosum and extraocular muscles were drawn. Signal intensity (SI) in the ROIs was measured and the SI ratio (SIR, SI of oculomotor nerve/SI of genu of corpus callosum) was calculated. Nine of 17 patients underwent contrast-enhanced coronal T1WI with fat suppression (CE-T1WI), and the SI ratios were also calculated.
Results
On IDEAL T2WI, the SIR of the affected and normal side of CN3 was 1.47 vs 0.95 ($p<0.05$) in the inflammatory disease, 1.53 vs 0.88 ($p<0.05$) in the compression disease, and 0.98 vs 0.77 in the muscular disease, respectively. On CE-T1WI, the SIR of the affected side and normal side of CN3 was 1.49 vs 1.02 ($p<0.05$) in the inflammatory disease, and 0.99 vs 1.08 in the compression disease. In five of six patients of oculomotor neuritis, high signal intensity in extraocular muscles due to denervation atrophy was observed.



Conclusion
IDEAL T2WI can offer clear images of CN3 abnormalities in disease presenting with CN3 palsy. The use of a contrast agent can distinguish the cause of CN3 palsy.

Can We Halt Vision Loss In Idiopathic Intracranial Hypertension with Venous Stenosis?

Seshadri, R.[1]·HR, A.[2]
[1]Sri Ramachandra Medical College, Chennai, INDIA, [2]National Institute of Mental Health and Neurosciences, Bangalore, INDIA.

Purpose
Idiopathic-intracranial-hypertension (IIH) is a disease entity of exclusion characterized by raised intracranial tension (ICT) with no obvious mass lesion or venous sinus thrombosis. It is characterized with intractable headaches, visual obscurations, papilledema; mainly affects obese women of child-bearing age. Multiple pathophysiologic mechanisms have been proposed to explain the increased intracranial pressure (ICP). In a subset of patients, venous sinus stenosis with a significant pressure gradient has been recognized. Three-dimensional phase contrast MRV,

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

contrast-enhanced MRV, cerebral angiography, retrograde venography and manometry help in identification of this subset of patients. The major problem caused by IIH is insidious painless loss of vision which can be halted and reversed to a certain extent, if detected and intervened early. The purpose of this study was to study the effectiveness of venous-sinus stenting in treating IIH due to venous-stenosis.

Materials & Methods

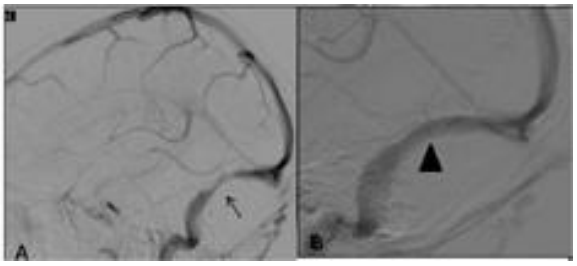
It was a prospective study. Ethical clearance was obtained. Inclusion criteria: Patients diagnosed with IIH, refractory to medical therapy and having venous stenosis with significant pressure-gradient(>/=10 mm of Hg). Exclusion criteria: Patients responding to medical management or venous stenosis with pressure-gradient of less than 10 mm of Hg or venous-sinus thrombosis or intracranial space-occupying lesions. All patients underwent detailed clinical, imaging and ophthalmologic examinations; CSF-analysis, CSF-pressure recording; vasculitic workup. Those fitting the inclusion criteria underwent DSA and manometry. Patients with significant pressure gradient (>/=10 mm of Hg) in venous sinuses were stented with self-expandable stents and pressure difference was recorded poststenting. Postintervention, clinical and ophthalmologic evaluations were performed, and repeat DSA with manometry was performed on followup.

Results

All of the six patients were females (age-range:15- 40 years; weight: 60-88 Kg; BMI: 29-37) (Table 1; Figure 1).

Results of Venous sinus stenting in IIH

case	CSF Pressure	Pre-Stenting visual acuity	Papilledema Right	Papilledema Left	Pre-Stenting Pressure Gradient-mm Hg	Post-Stenting Pressure Gradient-mm Hg	Post-Stenting. Papilledema Right	Post-Stenting Papilledema Left	Post-Stenting visual acuity	Post-Stenting Blurring
1	230	Normal	Present	Present	33	0	Improved	Improved	Normal	Resolved
2	100	Normal	Present	Present	30	4	Improved	Improved	Normal	Resolved
3	200	Normal	Present	Present	30	0	Improved	Improved	Normal	Resolved
4	400	Reduced	Atrophy	Present	32	1	Atrophy	Improved	Improved	Resolved
5	330	Reduced	Atrophy	Atrophy	15	2	Atrophy	Atrophy	Improved	Resolved
6	360	Normal	Present	Present	16	2	Improved	Improved	Normal	Resolved



Conclusion

This study clearly shows that whenever the cause of IIH is a stenosed venous sinus with a significant pressure gradient across the stenosis, stenting definitely helps in normalization of ICP with dramatic relief of symptoms. So it should be a primary modality of treatment in cases of significant venous-sinus stenosis refractory to medical management as it helps in halting the progression of visual loss due to raised ICP.

eP-110

Update on the Sonographic NASCET Index: A Revised Doppler Parameter for Assessment of Internal Carotid Artery Stenosis

Nayak, N. B.[1]·Abdulla, A.[2]·Huang, J.[3]·Hathout, G.[1,3]
[1]University of California Los Angeles, Los Angeles, CA, [2]2David Geffen School of Medicine at University of California, Los Angeles, CA, [3]Greater Los Angeles-West Los Angeles Veterans Administration Medical Center, Los Angeles, CA.

Purpose

Sonography using either a single peak systolic velocity (PSV) measurement alone or the ICA-CCA velocity ratio does not accurately reflect the North American Symptomatic Carotid Endarterectomy Trial (NASCET)-style methodology for assessing carotid artery stenosis. In a previous paper, a new Doppler parameter, the sonographic NASCET index (SNI), was derived by using the PSV at both the stenotic proximal ICA and distal normal ICA to calculate an ultrasound index directly analogous to NASCET methodology. Correlation between SNI and angiography was found to be greater than that of PSV and angiography, with better accuracy in predicting stenosis of 70% or greater. However, all these parameters use only a single time-point velocity measurement, at the peak of the cardiac cycle, which does not take into account complex changes affecting the Doppler waveform as a whole, such as increased diastolic flow in more narrow occlusions. We have devised an updated SNI, revised to integrate the true volume within the vessel at both the stenotic proximal ICA and distal normal ICA over the entire cardiac cycle, and to calculate a NASCET-style measurement of carotid stenosis.

Materials & Methods

Inclusion criteria were established as: angiographically proven carotid stenoses of 40-95%, measured proximal and distal internal carotid artery Doppler PSV values and correlating Doppler waveform images. Occlusions and near-occlusions were specifically excluded. Doppler and angiographic data meeting the inclusion criteria from 25 carotid bifurcations were identified; actual angiographic stenoses ranged from 40-92%. The integral of the area under the Doppler waveform curves was tabulated at both the proximal and distal internal carotid arteries to calculate the revised SNI for each vessel. Peak systolic velocity, ICA-CCA ratio, and SNI were correlated with angiography by using linear regression analysis. Accuracies of SNI and PSV in predicting stenoses of 70% or greater were compared at two thresholds.

Results

Correlation with angiography was found to be significantly better with SNI than either PSV or the ICA-CCA ratio (r^2 = 0.48 vs.0.22; r^2 = 0.48 vs. 0.16). Peak systolic velocity and SNI values that corresponded to 70% angiographic stenosis

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

were 296.5 cm/s and 42.4, respectively. The accuracy of PSV of 296.5 cm/s or greater in predicting stenosis of 70% or greater was 68%, compared with 80% for SNI of 42.4 or greater. The SNI value that corresponded to a PSV threshold of 230 cm/s, the threshold used in our ultrasound laboratory, was 34.4. The accuracy of PSV of 230 cm/s or greater in predicting hemodynamically significant stenosis was 72%, compared with 88% for SNI of 34.4 or greater.
Conclusion
When compared to conventional methodology of inferring the degree of stenosis from elevations of PSV in the stenotic segment without reference to the more normal distal ICA, or using the ICA-CCA ratio (comparing the stenotic segment to the CCA), the revised SNI correlates more closely with angiographic stenosis and is significantly more accurate in predicting stenosis of 70% or greater.

Diagnostic Accuracy of 64-Slice Multidetector CT Angiography in the Assessment of in-Stent Restenosis after Vertebral Artery Ostium Stenting

Yoo, W.[1]·Lee, Y.[1]·Kim, K.[2]·Kim, B.[3]
[1]Bucheon St. Mary's Hospital, Bucheon, KOREA, REPUBLIC OF, [2]Incheon St. Mary's Hospital, Incheon, KOREA, REPUBLIC OF, [3]Seoul St. Mary's Hospital, Seoul, KOREA, REPUBLIC OF.

Purpose
The aim of our study was to assess the diagnostic accuracy of 64-slice multidetector computed tomography angiography (CTA) for the detection of in-stent restenosis (ISR) after vertebral artery ostium (VAO) stenting and to compare these with conventional angiography.
Materials & Methods
Sixty-one stents of 54 patients (34 men, 20 women; mean age, 64 years; range, 48-82 years) were evaluated with 64-slice MDCT angiography. Three sets of images were reconstructed with three different convolution kernels. We assessed diagnostic accuracy for ISR (≥50% diameter narrowing) of VAO stents with CTA in comparison with conventional angiography as the reference standard. The mean interval between initial stent implantation and follow-up CTA was 8.2 ± 3.1 months (range, 3.7-20.4 months). The median interval between CTA and conventional angiography was one day (range, 0-24 days). Evaluations were performed by two observers who were blinded to the results of conventional angiography. Sensitivity, specificity, and positive and negative predictive values were calculated.
Results
By CTA, 52 stents (85.2%) were assessable and nine stents (14.8%) were not assessable. For assessable stents, with CTA, six of seven stents with ISR on conventional angiography were diagnosed correctly. The sensitivity, specificity, and positive predictive value, and negative predictive values for all stents were 90.0%, 84.3%, 52.9%, and 97.7%. However, when excluding unassessable stents, values were 85.7%, 95.6%, 75.0%, and 97.7%. There was no significant difference between CTA and conventional angiography for the detection of ISR after VAO stenting (McNemar test, p = 1.00).
Conclusion
Sixty-four-slice MDCT angiography has high diagnostic value for ruling out significant in-stent restenosis after VAO stenting with high negative predictive value.

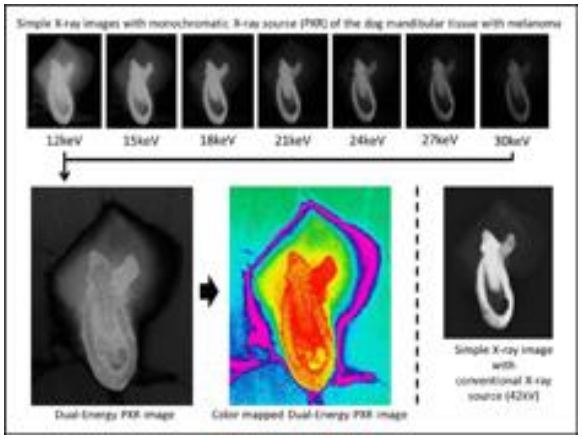
Monochromatic Imaging with Parametric X-ray: A Basic Study

Sekiya, K.[1]·Kaneda, T.[1]·Suemitsu, M.[1]·Hayakawa, Y.[2]·Sakae, T.[1]
[1]Nihon University School of Dentistry at Matsudo, Chiba, JAPAN, [2]Nihon University, Chiba, JAPAN.

Purpose
Parametric radiation-based x-ray (PXR), one of the pioneering studies using accelerator, is studied and expected for a new x-ray source with unique features different from conventional x-ray. In the Laboratory for Electron Beam Research and Application institute of quantum science (LEBRA), the PXR is generated with relatively a small linear accelerator (125MeV) and silicon crystal. The LEBRA-PXR has several unique characteristics, such as a tuneable wavelength, a nearly perfect mono-chromatid, a nearly perfect parallel beam, and high spatial coherence. All of these features are effective for the x-ray imaging and absorption studies. The purpose of this study was to evaluate the potential of LEBRA-PXR as a new x-ray source modality for imaging diagnosis.
Materials & Methods
The subject was a dog mandibular tissue with melanoma. Simple x-ray images were taken with LEBRA-PXR in several wavelengths (12 keV, 15 keV, 18 keV, 21 keV, 24 keV, 27 keV, 30 keV). An energy-subtracted image was generated with the image with the lowest wavelength PXR and the image with the shortest wavelength PXR. The subject was cut, H&E stained, and viewed with a microscope. As a control, an image was taken with conventional x-ray (42 kV, 125 mA, 40 msec; effective energy 21 keV). X-ray images were compared with the histopathologic images.
Results
Compared to conventional x-ray, LEBRA-PXR images showed contrast related to different wavelengths, reflecting histologic differences between tissues. Energy subtraction imaging with LEBRA-PXR offered more information of the lesion with regard to energy absorption coefficient of the tissues.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Conclusion
Using LEBRA-PXR, nearly perfect monochromatic x-ray source imaging, the images displayed different contrasts from conventional x-ray. Therefore, LEBRA-PXR may be useful for diagnostic imaging as a new x-ray source.

Vascular Mapping of the External Carotid Artery System: Comparison of the Visibility between CT Angiography with 64-Slice Multidetector CT and 3D Time-of-Flight MR Angiography at 3T

Iida, E.･Furukawa, M.･Kudomi, S.･Kato, M.･Kishi, T.･Matsunaga, N.
Yamaguchi University Graduate School of Medicine Ube, JAPAN.

Purpose
The knowledge of a patient's individual vascular mapping of the external carotid artery (ECA) system would benefit interventional radiologists for treatment planning in the head and neck disorders. The spatial resolution of CT angiography (CTA) has improved, and CTA with volume-rendering (VR) technique allows for assessment of vascular anatomy of the ECA systems. Time-of-flight MR angiography (TOF MRA) is less invasive and might be an alternative option, but saturation effects often lead to signal reduction of the ECA branches and may influence their visibility. The purpose of this study is to compare the visibility of major branches of the ECA between CTA and TOF MRA by using VR images.
Materials & Methods
Ten patients with head and neck tumor underwent both CTA with 64-slice multidetector CT and three-dimensional TOF MRA on 3T before common carotid arteriography and treatment with interventional radiology. Volume-rendering images of CTA and MRA were reconstructed by two independent radiologists. With two-dimensional digital subtraction angiography (DSA) and three-dimensional rotational DSA of common carotid artery as reference standard, the presence and the length from the origin were evaluated for the following 11 ECA branches (superior thyroid artery, lingual artery, facial artery, ascending pharyngeal artery, occipital artery, posterior auricular artery, internal maxillary artery, middle meningeal artery, accessory meningeal artery, superficial temporal artery and transverse facial artery) on VR images of CTA and MRA. The length from the origin of each artery was graded on a five-point scale (0: none, 1: less than 1 cm, 2: less than 2 cm, 3: less than 3 cm, 4: 3 cm or longer). Wilcoxon signed-rank test was used to determine differences between CTA and TOF MRA. A two-sided value of $P<0.05$ was considered significant.
Results
Two hundred eight branches of 19 ECA in 10 patients (total) were evaluated. For the presence of those branches, 152 branches (73.1%) were identified on CTA, while 181 branches (87.0%) were identified on TOF MRA ($P<0.05$). TOF MRA was superior to CTA in two branches (ascending pharyngeal artery and middle meningeal artery), while there was no statistically significant difference between CTA and TOF MRA in the remaining nine branches. For the length from the origin of each branch, mean score of all branches was 2.63 ± 1.77 for CTA and 2.75 ± 1.47 for TOF MRA, and there was no significant difference. CT angiography was superior to TOF MRA in two branches (superior thyroid artery and lingual artery), while TOF MRA was superior to CTA in two branches (ascending pharyngeal artery and middle meningeal artery). There was no significant difference between CTA and TOF MRA in the remaining seven branches.
Conclusion
Three-dimensional TOF MRA with VR is a noninvasive tool that can provide details of ECA branches, and would be an alternative option for treatment planning of interventional radiology in the head and neck disorders.

Correlation between Cyst Content CT Value and Microvessel Density in Keratocystic Odontogenic Tumor of the Mandible

Sekiya, K.[1,2]･Suemitsu, M.[1,2]･Kuno, H.[2]･Satake, M.[2]･Kaneda, T.[1]
[1]Nihon University School of Dentistry at Matsudo, Chiba, JAPAN, [2]National Cancer Center Hospital East, Chiba, JAPAN.

Purpose
Keratocystic odontogenic tumor is a locally aggressive developmental cystic neoplasm with a high recurrence rate. Previous studies have indicated that microvessel density is a histopathologic parameter that can be

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

indicative of lesion activity. Measurement of the CT value of the cyst content is a simple method for assessing the proportions of the various components. The present study was conducted to investigate the correlation between the CT value and microvessel density in keratocystic odontogenic tumor of the mandible.

Materials & Methods

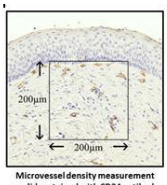
Nineteen subjects with histopathologically confirmed keratocystic odontogenic tumor who underwent preoperative CT examinations between April 2006 and November 2011 were enrolled in this retrospective study. There were nine males (47%) and 10 females (53%), ranging in age from 11 to 70 years (median, 39 years). The average cyst content CT values for all subjects were measured on axial noncontrast CT images of the lesions. The subjects were divided into two groups according to the presence or absence of high CT value spot. The high CT value spot was defined as higher than 90 HU, by reference to previous studies. Histopathologically, microvessel densities in all subjects were also measured on slides immunohistochemically stained with CD34 antibody (Figure 1). Statistical analysis of the correlation between the cyst content CT value and microvessel density was carried out using Pearman's rank correlation coefficient. The significance of differences in microvessel density between the two groups discriminated according to the highest CT value for the cyst content was tested using the Mann-Whitney U test.

Results

The average cyst content CT value was 31.1 ± 14.3 HU, and five subjects (26%) had the high CT value spot. The average microvessel density was 9.3 ± 3.8 per 40000 μm. Cyst content CT values were correlated with the microvessel density of the lesions (r = .48, P = .036) (Figure 2). Subjects who had high CT values spot showed a significantly higher microvessel density in the lesions (P < .05).

Conclusion

It is suggested that the cyst content CT value is correlated with microvessel density in keratocystic odontogenic tumor of the mandible, and therefore may be applicable as a parameter for prediction of local aggressiveness and potential for recurrence.



Microvessel density measurement on slides stained with CD34 antibody

Assessment of Follow-Up Ultrasonography and Clinical Improvement among Infants with Congenital Muscular Torticollis

Park, H. J.
Sungkyunkwan University School of Medicine, Kangbuk Samsung Hospital
Seoul, KOREA, REPUBLIC OF.

Purpose

To evaluate whether a new ultrasonographic assessment method that utilizes the muscular thickness ratio of the SCM can help quantify the outcome of rehabilitation therapy for patients with congenital muscular torticollis (CMT).

Materials & Methods

We evaluated 48 patients (M:F = 17:31; mean age, 3.9 months) who were diagnosed with CMT and who underwent initial and follow-up ultrasonography. The ratio of the thickness of the involved SCM to the thickness of the intact SCM ("SCM thickness ratio") was calculated. A scoring system based on the range of motion of the neck was used to assess clinical improvement. The correlations between clinical improvement and the thickness of the involved muscle, the difference in involved muscle thickness, the SCM thickness ratio, and the difference in the SCM thickness ratio were evaluated with Spearman rank correlations.

Results

Follow-up Cheng scores were higher than initial scores, which indicate clinical resolution (followup, 4.90; initial, 3.38). The SCM thickness ratio at followup was lower than at the initial evaluation (followup, 1.29-1.34; initial, 1.65-1.77). Intra and interobserver agreements were excellent. Most variables were moderately correlated with clinical improvement (correlation coefficients: 0.36-0.509). R1 showed the highest correlation with clinical improvement (0.481 and 0.509), followed by the initial maximal thickness of the SCM (0.434 and 0.488). ΔP (P1-P2) and ΔR showed similar correlation coefficients with clinical improvement.

Conclusion

Measurement of the SCM thickness ratio appears to overcome the problem of a false positive diagnosis of clinical aggravation of CMT resulting from physiologic growth. R1 and ΔR are accurate, objective measurements that can be used in the management of CMT.

Ultrasound Predictors of Thyroid Malignancy: Correlating with Ultrasound-Guided Biopsy and Thyroidectomy

Chen, B. T.·Jain, A. B.·Dagis, A.·Vora, L.·Maghami, E.·Salehian, B.
City of Hope Medical Center
Duarte, CA.

Purpose
Thyroid ultrasound has been used extensively for evaluation of thyroid nodules. Well documented ultrasound features associated with thyroid malignancy include micro or macro calcifications, poorly defined margin, hypoechogenicity, taller-than-wide shape and hypervascularity. Ultrasound features of thyroid nodules play important role in clinical management. The purpose of this study is to determine the prevalence of thyroid malignancy, and to evaluate ultrasound predictors of thyroid malignancy. This study compared the ultrasound features with ultrasound-guided biopsy results. It further tested the ultrasound predictors in the subset patients who went on to have thyroidectomy.
Materials & Methods
All consecutive ultrasound-guided thyroid biopsy procedures from 1/2007 to 12/2011 were reviewed retrospectively for ultrasound characteristics and ultrasound-guided biopsy results. Pathology reports from the subset of patients who went on to have hemi/total thyroidectomy also were reviewed. Multivariate logistic regression models were constructed for testing predictors of malignancy. All p values were reported significant at less than 0.05 from either Fisher's exact test or from Wilcoxon test.
Results
A total of 461 thyroid nodules in 350 patients underwent ultrasound-guided thyroid biopsy procedures during the study interval. Of these, 32 (7%) nodules were excluded from the study due to inadequate sampling, leaving 429 nodules available (median age 58 years ranging from 14 to 88, female 80% versus male 20%). Surgical excision with hemi/total thyroidectomy was performed in 105 (24.5%) thyroid nodules. Of the 429 biopsies, 38 (9%) were reported as malignant or suspicious for malignancy. Male patients have significantly higher chance of malignancy found in biopsy compared to females [(19% versus 6%, p = 0.001 in Fisher's exact test), Odds ratio (95% Confidence Interval): 2.74 (1.24, 6.02)]. Ultrasound features that significantly predict malignancy on biopsy included: ultrasound micro calcifications with p <0.001 and Odds ratio (95% confidence interval): 7.16 (2.95, 17.4), Ultrasound coarse or eggshell calcification in thyroid biopsy with p = 0.002 and Odds ratio (95% confidence interval): 4.49 (1.77, 11.4). Thyroid nodule size and other ultrasound features such as hypoechogenicity, increased vascularity, taller-than-wider, and ill-defined margins are weak predictors of thyroid malignancy. In the subset cohort with subsequent hemi/total thyroidectomy (n = 105), ultrasound biopsy results significantly predict malignancy in surgery with p<<0.0001, Odds ratio and confidence interval: 67.3 (18.3, 248). Ultrasound microcalcification predicts malignancy in surgery with p = 0.02, Odds ratio and confidence interval: 3.33 (1.24, 8.93). Ultrasound coarse or eggshell calcification predicts malignancy with p = 0.0006, Odds ratio and confidence interval: 8.48 (2.48, 28.9). Ultrasound hypoechogenicity predicts malignancy in surgery with p = 0.02, Odds ratio and confidence interval: 4.49 (1.23, 16.3). Ultrasound nodule shape predicts malignancy with p = 0.05, Odds ratio and confidence interval: 5.40 (0.99, 29.4).
Conclusion
The prevalence of thyroid malignancy in our cohort is 9% on biopsy. Micro, coarse or eggshell calcifications significantly predict malignancy on biopsy, which is further validated in the subset cohort with subsequent thyroidectomy. Male patients have significantly higher chance of malignancy found in biopsy compared to females. Ultrasound biopsy results significantly predict malignancy in surgery.

KEYWORDS: Thyroid, Ultrasonography, thyroid nodules

Effect of Radiotherapy on Dynamic Contrast-Enhanced Perfusion Parameters in the Head and Neck

Ishiyama, M.[1]·Richards, T.[1]·Parvathaneni, U.[1]·Furukawa, M.[2]·Anzai, Y.[1]
[1]University of Washington, Seattle, WA, [2]Yamguchi University, Yamaguchi, JAPAN.

Purpose
Dynamic contrast-enhanced (DCE) MRI allows us to obtain quantitative information of microvascular environment. Dynamic contrast-enhanced MR has the potential to differentiate malignant from benign tumors, post-treatment changes from recurrent tumors, and predict treatment response. Chemoradiotherapy is often the primary treatment for advanced stage head and neck cancer. Radiotherapy (RT) may alter the microvascular profile in tumors and the surrounding normal tissues. To interpret DCE MR changes in posttreatment patients, it is essential to understand the impact of radiation on the perfusion parameters of normal head and neck tissues. The aim of this study was to investigate the effects of radiotherapy on the DCE MRI perfusion parameters of the microvascular environment of the normal tissue among patients with previously treated head and neck cancer.
Materials & Methods
Thirty-three patients (27 men and 10 women, mean age; 55.9 years) who underwent DCE MRI for evaluation of head and neck cancer were enrolled retrospectively in this study. Nine patients were treated previously with RT to the head and neck region. Mean time from completion of the therapy to DCE MRI was 23.9 months. Dynamic contrast-enhanced MRI protocol was based on 3D T1-

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

weighted acquisition with time resolution of 2.6 seconds and total acquisition time of 4 minutes 17 seconds (100 dynamic volumes). Quantitative values including permeability surface area (PS) and tumor blood volume (BV) (estimated as area under intensity curve) were obtained from eight locations in the normal tissue. Permeability surface area parameters were obtained using a modified Tofts model. The quantitative values were compared between patient with and without RT, as well as duration after the completion of RT. Wilcoxon signed-rank test was used for analysis.
Results
The number of examined structures depended on the range of scan in each patient because not all of the study covered entire head and neck region. Quantitative values were obtained from the parotid gland (n = 27), submandibular gland (n = 22), tongue (n = 21), floor of mouth (n = 18), medial pterygoid muscle (n = 23), palatine tonsil (n = 25), posterior cervical muscles (n = 31), and cervical spinal cord (n = 33). There were no statistical differences between patients with and without radiotherapy in PS and BV in each location. No statistical difference was observed in PS and BV between patients less than one year from the completion of RT and more than one year from RT.
Conclusion
Radiotherapy has little effect on PS and BV in the normal tissues of the head and neck region. This suggests validity of using ratio between tumor and normal muscles, salivary gland tissues, spinal cords, or palatine tonsil in the head and neck.

Clinical Usefulness of ^{18}F-FDG PET/CT and CT/MR Imaging for Detecting Nodal Metastasis in Patients with Hypopharyngeal Cancer

Kim, J.·Shin, N.·Kim, K.·Lee, J.·Koh, Y.
Yonsei University College of Medicine
Seoul, KOREA, REPUBLIC OF.

Purpose
To assess the clinical usefulness of ^{18}F-FDG PET/CT and CT/MRI for preoperative planning of contralateral neck dissection in patients with hypopharyngeal squamous cell carcinoma (SCC).
Materials & Methods
In total, 35 hypopharyngeal SCC patients who underwent primary site resection with uni or bilateral neck node dissection were evaluated retrospectively. No patient had distant metastasis or history of prior treatment. Every patient underwent PET CT and CT/MRI, and histopathologic analysis was used as the gold standard for assessment of each imaging technique.
Results
Of the 45 patients, 35 (77.8%) had neck node metastasis and 12 (26.7%) had contralateral neck node metastasis. On a level-by-level basis, the accuracy of PET CT for nodal metastases was higher than that of CT/MRI (89.0% vs. 94.0%, p = 0.046). In addition, although three (13.0%) of the 23 patients with palpably negative neck (N0) showed contralateral neck node metastasis, the patients who showed no evidence of ipsilateral nodal metastasis on PET CT and CT/MRI revealed no occult contralateral neck metastasis.
Conclusion
^{18}F-FDG PET/CT has additional values for the preoperative prediction of nodal metastasis in patients with hypopharyngeal cancer. In clinically N0 patients, ^{18}F-FDG PET/CT may prevent them from undergoing unnecessary contralateral neck dissection.

KEYWORDS: Head and neck, PET/CT, lymph node metastasis

eP-119

Clinical Usefulness of ^{18}F-FDG PET/CT for Detecting Nodal Metastasis in Patient with Oropharyngeal Cancer Compared to CT/MR Imaging

Kim, J.·Kim, I.·Choi, Y.·Sohn, B.·Lee, J.·Koh, Y.
Yonsei University College of Medicine
Seoul, KOREA, REPUBLIC OF.

Purpose
To investigate the clinical usefulness of ^{18}F-FDG PET/CT for the preoperative prediction of nodal metastasis in clinically N0 patients with oropharyngeal squamous cell carcinoma (SCC), by comparing with CT and/or MRI.
Materials & Methods
In total, 118 oropharyngeal SCC patients who underwent primary site resection with uni or bilateral neck node dissection were evaluated retrospectively. No patient had distant metastasis or history of prior treatment. Every patient underwent PET CT and CT/MRI, and histopathologic analysis was used as the gold standard for assessment of each imaging technique.
Results
On a patient-by-patient basis, the accuracy of PET CT for nodal metastases was higher than that of CT (77.6% vs. 68.9%, p = 0.015) and MRI (77.6% vs. 66.7%, p = 0.003). Visual correlation of CT/MRI and PET CT yields slightly higher accuracy than CT (73.5% vs. 68.9%, p = 0.020) or MRI alone (73.5% vs. 66.7%, p = 0.028). In addition, 49 (41.5%) of our 118 patients showed clinically negative neck (N0), and the sensitivity for occult neck node metastases in N0 patients was 59.1% in CT, 50.0% in MRI, and 64.0% in PET CT. Ten patients (20.4%) were falsely negative in CT/MRI and nine (18.4%) were falsely negative in PET CT.
Conclusion
Positron emission tomography CT was more accurate than CT/MRI for detecting neck node metastasis of oropharyngeal SCC. In clinically N0 patients, as the

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

sensitivity of PET CT as well as CT/MRI was still low, elective neck node dissection should be followed.

KEYWORDS: Oropharynx, PET/CT, lymph node metastasis

Native versus Radiation-Induced Soft Tissue Sarcomas of the Head and Neck

Eliahou, R.·Learned, K.·Lustig, R.·Alonso-Basanta, M.·Loevner, L.
Hospital of University of Pennsylvania
Philadelphia, PA.

Purpose
Sarcomas of the head and neck in adults are uncommon accounting for approximately 0.1% of annual malignancies in the U.S. Radiation-induced sarcoma of the head and neck is a rare, late complication of radiation therapy. Native and radiation-induced sarcomas are different clinical entities with different clinical course and management. Radiation-induced sarcomas are treated primarily with surgical excision and have a poor prognosis. The purpose of this study is to evaluate and compare the imaging findings of native versus radiation-induced head and neck sarcomas.
Materials & Methods
We retrospectively reviewed our institution sarcoma database from 2002- 2012 to identify patients with head and neck sarcomas for whom we had CT and/or MR imaging from their initial presentation. Their imaging and medical records including histopathology, clinical course, and radiation dose/protocol for those sarcomas that were radiation-induced were reviewed. The masses were evaluated for anatomical locations, borders, size, and tissue characterization (CT attenuation, T1 and T2 signal intensity, and enhancement).
Results
Eight patients had native head and neck sarcomas (four male, four female, mean age 60 years) and eight patients had radiation-induced sarcomas (four male, four female, mean age 57 years). The radiation-induced sarcoma group received a mean total radiation dose of 68 Gy and had a mean latency period for the development of the sarcoma in the irradiated field of 13 years. The most common primary diagnosis treated with radiation was nasopharyngeal squamous cell carcinoma in three of eight patients. The most common sarcoma histopathology for both groups was soft tissue spindle cell sarcoma (seven of eight in the radiation group, five of eight in the native group). Most sarcomas were high-grade (six of eight in the native group, and eight of eight in the radiation group). The most common anatomical location of adult sarcomas was skull base occurring in six of eight in the radiation group and three of eight for the native group. Enhancing large masses (4.1 cm average size for both groups) was typical. For the native group, six of eight masses were well circumscribed, none necrotic, three of eight involved bone with chronic as well as focal permeative changes. For the radiation group, all sarcomas had poorly defined margins, necrosis was seen in 50%, and six of eight were associated with permeative bone erosion.
Conclusion
Native and postradiation sarcomas of the head are uncommon, and are different clinical entities. Although imaging findings are not pathognomonic and share some similarities, radiation-induced masses have infiltrative margins, necrosis is frequent as is permeative bone destruction, compared to native tumors which are more circumscribed, frequently solid, with less aggressive bone changes. In the radiated group high clinical suspicion for treatment-induced sarcoma in the appropriate setting is important, as these are not uncommonly initially misinterpreted for neoplastic recurrence.

eP-121

Differentiation of Recurrent Tumor from Postradiation Changes on DCE MR Perfusion in the Head and Neck Region

Ishiyama, M.[1]·Parvathaneni, U.[1]·Richards, T.[1]·Furukawa, M.[2]·Anzai, Y.[1]
[1]University of Washington, Seattle, WA, [2]Yamaguchi University, Yamaguchi, JAPAN.

Purpose
Conventional MR or CT imaging has limitations in differentiating post-treatment changes from recurrent tumors following chemoradiotherapy among head and neck (HN) cancer patients. Dynamic contrast-enhanced (DCE) MRI potentially serves as surrogate of microvascular environment, such as leakiness of blood vessels or microvascular density. We hypothesize that DCE parameters such as permeability surface area (PS) and tumor blood volume (BV) (estimated as area under intensity curve) are useful in differentiating a recurrent tumor from post-treatment inflammation or fibrosis. The purpose of this study is to investigate the usefulness of quantitative microvascular parameters in head and neck cancers.
Materials & Methods
This retrospective study included consecutive 29 patients (22 men and seven women, mean age: 56.2 years) who underwent DCE MRI on a 3T scanner. Of 29 patients, 16 patients had newly diagnosed biopsy-proven untreated primary HN cancers, seven patients had biopsy-proven recurrent HN cancers, and six patients had benign post-treatment enhancement confirmed by clinical follow-up examinations. Dynamic contrast-enhanced MRI protocol was based on 3D T1-weighted acquisition with time resolution of 2.6 seconds and total acquisition time of 4 minutes 17 seconds (100 dynamic volumes). An experienced radiologist drew regions of interest to include entire lesion using conventional MR images as anatomical

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

reference. Four points in the internal carotid artery were selected and averaged for the arterial input function. Quantitative values including PS and blood volume (BV) were calculated on in-house software (modified Tofts model) and they were compared between the tumor group (primary and recurrent HN cancers) and the nontumor group (benign post-treatment enhancement). Wilcoxon signed-rank test was used for analysis.
Results
Permeability surface areas were 2.4 x 10 -4 +/- 1.6 10 -4 (mean ± SD) in the tumor group (n = 23) and 4.8 x 10 -4 +/- 8.3 10 -4 in the nontumor (post-treatment) group (n = 6). There was a statistically significant difference (p = 0.03) between the two groups (p = 0.03). In contrast, no statistically significant difference was observed in BV between these two groups (p = 0.085).
Conclusion
Post-treatment changes in the head and neck region had markedly high permeability property. There was no significant difference in BV between tumors and post-treatment changes.

KEYWORDS: Dynamic contrast-enhanced MR, Permeability MR imaging

Assessment of the Necrosis in the Cervical Lymph Nodes: Diagnostic Value of Contrast-Enhanced Ultrasonography Compared with Enhanced CT and Pathologic Findings

Kato, M.·Iida, E.·Furukawa, M.·Fujita, T.·Tanabe, M.·Oga, A.·Matsunaga, N.
Yamaguchi University
Ube, JAPAN.

Purpose
In the lymph node staging of head and neck squamous cell carcinoma (HNSCC), central necrosis is a characteristic feature suggesting metastatic nodes. Contrast-enhanced ultrasonography (CE US) provides sensitive vascular flow images, and we hypothesized that CE US would improve diagnostic accuracy for the detection of necrotic nodes. The purpose of this study is to assess the value of CE US for identifying the nodal necrosis compared with that of contrast-enhanced CT (CECT), which is widely used for nodal staging.
Materials & Methods
Consecutive 17 patients (age range: 42-91 years; mean age, 66 years) with histologically proven HNSCC were included in this study. Both CE US and CE CT were performed for preoperative nodal staging, and the interval among imaging examinations and operation was within 1 month (mean interval between both examination: 9.4 days, mean interval between first examination and operation: 21.4 days). Two radiologists independently reviewed images regarding the presence of nodal necrosis with a four-point grading scale. Those findings were compared with pathologic findings, which were used as a standard reference, for each individual node. Interobserver and intermodality agreements were calculated. The diagnostic performance of each modality for detecting the necrotic lymph node was analyzed, and compared statistically. ROC analysis also was performed.
Results
Ten of 17 patients had metastatic nodes. Of the total of 53 dissected lymph nodes, 17 nodes were metastatic nodes and 14 of them had necrosis on pathology. The mean short-axis diameter of necrotic nodes was 5.4 mm (range ±3.4 mm). Regarding the evaluation of nodal necrosis, the interobserver agreement was excellent on both modalities (CE US: κ = 0.91, CE CT: κ= 0.94), and the intermodality agreements also were excellent (reviewer 1: κ = 0.90, reviewer 2: κ= 0.92). The sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy was 93%, 95%, 87%, 97%, 93% on CE US, and 93%, 92%, 81%, 97%, 91% on CE CT, respectively. Between both modalities, there was no significant difference for the diagnostic performance. On ROC analysis, the value of area under the curve was 0.93 on CE US and 0.94 on CE CT, respectively.

A 59 year-old patient with carcinoma of lower gingiva. Low attenuation area is seen in the superior deep cervical lymph node on CECT (A) and corresponds to hypoecholcanea on CEUS (B). A necrotic lymph node metastasis is pathologically confirmed.

Conclusion
Although ultrasonography has some shortcomings such as operator dependency, CE US showed a highly diagnostic performance for identifying necrosis in the metastatic lymph nodes without any radiation exposure. Combined diagnostic criteria with CE US may be a powerful diagnostic tool for lymph node staging in HNSCC.

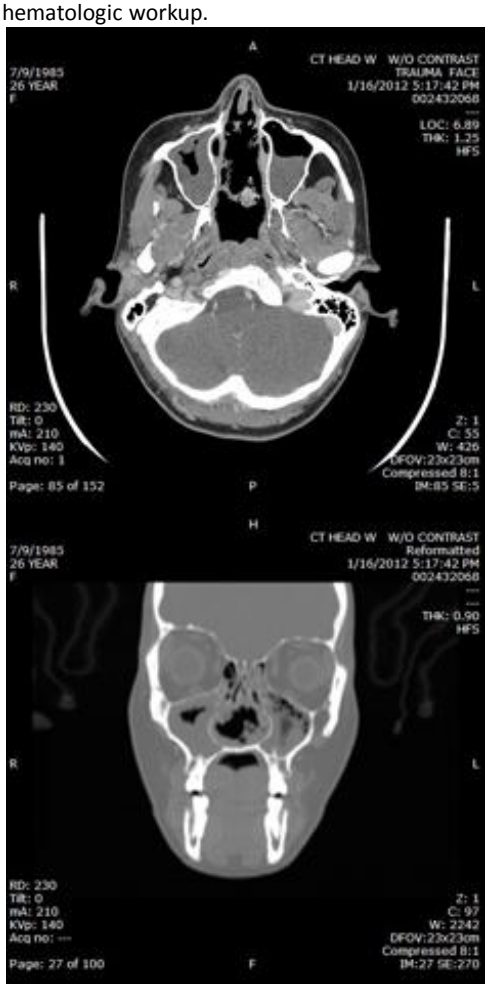
Invasive Fungal Sinusitis with Aspergillosis in an Immunocompetent Patient

Iqbal, S.·Joshi, A.·Zuberi, A.·Iqbal, M.
University of Kansas School of Medicine Wichita
Wichita, KS.

Purpose
Invasive fungal sinusitis with Aspergillus rarely has been

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

described in an immunocompetent patient.
Materials & Methods
CT imaging details the invasive nature of Aspergillus epidentered in the maxillary sinus and subsequently invading through to the nasal cavity with destruction of nasal trubinates, bony nasal septum, as well as the soft palate. Additionally, a full clinical workup of the patient is presented to explore etiologies and underlying conditions for the patient's presentation. She presents to the ER with "a hole in the roof of my mouth." Detailed history, extensive hematologic workup in order to exclude any immunodeficiency, and biopsy for pathologic diagnosis were reviewed. Follow-up imaging also was obtained at our institution.
Results
CT Imaging of a young healthy female patient demonstrates an invasive, destructive process, epicentered in the maxillary sinuses with destruction of the nasal turbinates, nasal septum, and soft palate. The samples sent to pathology obtained by the otolaryngologist, confirmed the destructive nature of the infection and the smears were positive for a fungal etiology, which grew out Aspergillus. No congenital or acquired immunodeficiencies were found upon extensive hematologic workup.



Conclusion
We describe an unusual case of invasive Aspergillus sinusitis in a pregnant patient with otherwise no immunodeficiencies. Our hypothesis is that her chronic use of cephalexin for acne may have altered the sinonasal flora, predisposing her to develop invasive Aspergillus sinusitis.

KEYWORDS: Sinonasal disease, Invasive fungal, immunocompetent

eP-124

Clinical Significance of Incidental Torus Tubarius Calcification

Buch, K.[1]·Nadgir, R.[1]·Ozonoff, A.[2]·Sodagari, F.[1]·Sakai, O.[1]
[1]Boston Medical Center, Boston, MA, [2]Harvard School of Public Health, Boston, MA.

Purpose
Calcification of the torus tubarius rarely has been reported in the literature. Histopathologic studies previously have described cases of Eustachian tube calcification and describe an association with increasing patient age. To our knowledge, a large study examining the prevalence of torus tubarius calcification and potential clinical significance on an unrestricted patient population using thin-section CT has not been reported.
Materials & Methods
Following IRB approval, 1000 patients were included in this study and consecutive noncontrast brain CT scans between January 2011 and February 2011 were reviewed retrospectively for presence of torus tubarius calcifications. Note was made as to whether these calcifications were unilateral versus bilateral. Studies were acquired axially at 1.25 mm slice thickness on 64-detector row CT scanners. Electronic medical records were reviewed on all subjects, and clinical parameters including age, gender, random glucose, hemoglobin A1C, alkaline phosphatase levels, and chronic medical conditions including diagnosis of diabetes, alcoholism, HIV, and renal disease were recorded. Severely motion-limited studies, follow-up examinations if performed, and subjects with limited clinical data were excluded. Statistical analysis of imaging and clinical data was performed using a Fisher test.
Results
Study population consisted of 974 patients with 459 males (mean age, 51 years) and 515 females (mean age, 54 years), ranging in age from 1 month to 100 years. Seven patients out of 974 were found to have torus tubarius calcifications with an overall prevalence of 0.7%. Four out of seven patients had bilateral calcification of the torus tubarius (57.1%) compared to three out of seven patients with unilateral calcification of the torus tubarius (42.9%). There was no statistically significant correlation between diabetes mellitus, HIV or renal disease and prevalence of torus tubarius calcification. There was an increased

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

prevalence of elevated alkaline phosphatase in patients with torus tubarius calcification; however, after controlling for age and gender there was no statistically significant correlation. There was no statistically significant correlation between patient age and presence of torus tubarius calcification.
Conclusion
Calcification of the torus tubarius is rare with an overall prevalence of 0.7%, based on the largest series to date on an unrestricted population using thinner section CT imaging. While the clinical significance remains uncertain, there is no statistically significant association between the presence of torus tubarius calcification and common medical conditions or increase in age.

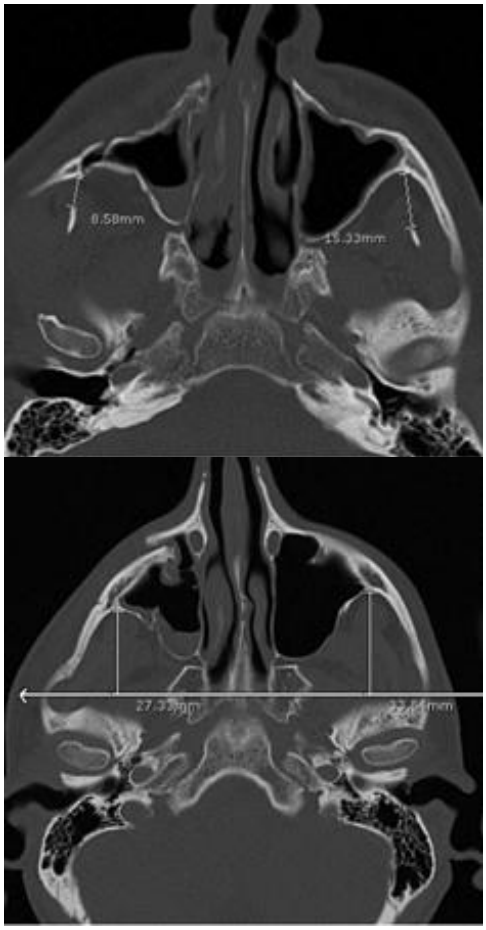
KEYWORDS: Calcifications, Incidental findings, Torus Tubarius

eP-125

CT Findings in Zygomatic Complex Fractures with Trismus

Johnson, J. M.[1]·Morgan, J. N.[2]·Troulis, M.[1]·Rubin, P.[3]·Caruso, P. A.[1]
[1]Massachusetts General Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA, [3]Boston Eye Physicians and Surgeons, Boston, MA.

Purpose
To review the CT imaging findings in patients with zygomatic complex fractures (ZCF) to determine if certain findings are predictive for the development of trauma-induced trismus.
Materials & Methods
CT images of 30 patients (8 female), age range 14-85 years, with zygomatic complex fractures were reviewed. Patients with mandibular fractures were excluded. The CT imaging for each patient was reviewed and the following elements were recorded: fracture or intactness of the zygoma, the zygomatic sutures, the maxilla, the sphenoid bone and the temporal bone and the relationship of fracture fragments to the mandible and zygomatic arch. Evaluation also was performed on the relationship of the fracture components and regional soft tissues and muscles of mastication.
Results
Sixteen of the 30 patients reported trismus. Two measurements were statistically significant in relationship to the presence of trismus. A measure of retroposition of the zygomatic body between the fractured side and the contralateral normal side revealed a difference of 4.44 mm, (± 3.12) in the trismus group compared to 2.43 mm (± 1.88) in the group without trismus (p = 0.04). The difference of the distance between the coronoid process of the mandible and the zygomaticomaxillary suture between the fractured side and the contralateral normal side was 4.13 mm (± 3.03) in the group with trismus and 2.21 mm (± 1.93) in the group without trismus (p = 0.05).



Conclusion
Greater degrees of retroposition of the zygomatic body and narrowing of the space between the zygomaticomaxillary suture and the coronoid process are associated with trismus in the setting of ZCF. These elements should be evaluated routinely in this type of injury.

Identifying the Malignant Parotid Neoplasm: Evaluation of Imaging Characteristics

Klatt-Cromwell, C. N.·Pina, S.·Chiu, W.·Jewells, V.·Hackman, T. G.
University of North Carolina Chapel Hill
Chapel Hill, NC.

Purpose
Parotid gland masses are comprised of a diverse array of lesions encompassing many benign and malignant entities. While approximately 85% of all tumors are thought to be benign, such as pleomorphic adenomas and Warthin's tumors, the remaining lesions include various malignancies and metastatic disease. With the aggressive behavior of some malignancies, including mucoepidermoid carcinoma

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

(ME), acinic cell carcinoma (ACC), adenoid cystic carcinoma (ADC), and carcinoma ex pleomorphic adenoma (CPA), earlier detection is of paramount importance. There is limited discussion in the literature regarding characteristic CT findings for these pathologies and their predictive nature. We hypothesize usage of standardized grading characteristics on imaging may help predict the presence of malignancy pre-operatively. Therefore, the aim of this study was to identify the imaging characteristics of parotid masses that may more accurately diagnose and classify malignant lesions.

Materials & Methods

Retrospective cohort study evaluating patients identified to have parotid masses based on pathology record search over a five-year period. Inclusion criteria were all patients presenting with parotid masses with CT imaging. Lesions of skin origin with parotid infiltration were excluded. Using a blinded approach, patients' pathology reports and imaging were assessed and classified by independent physicians. Three imaging characteristics were used to assess the cohort. Each patients' parotid mass was evaluated for the presence of the following characteristics: lobulated appearance, poorly-defined borders, and infiltration (finger-like projections). Pathology specimens were assessed for final pathologic grading, evidence of infiltration, and margin status. Univariable and multivariable logistic regression models were used to evaluate the association between imaging characteristics and malignancy.

Results

Two hundred eighty-five patients, 129 females and 156 males, ages 7-92 years were identified with parotid masses. Two hundred twenty-nine patients were found to meet all inclusion criteria to undergo analysis. Of these, 80 patients (35%) had malignancies, including 27 (34%) ME, 13 (16%) ACC, 5 (6%) CPA, and 2 (3%) ADC. Results from univariable models demonstrate that infiltration (p<.0001) and margin definition (p=0.01) are significantly associated with malignancy. Those with infiltrative front are 12 times more likely to be associated with malignancy [OR=12 (95% CI: 5.5-26)]. Patients with poorly defined borders are two times more likely to represent malignancy [OR=2 (95% CI: 1.2-3.6)]. Assessing three characteristics together, infiltrative front remains strongly associated with the malignancy (p<.0001).

Table 1: Multivariate Analysis

Model Covariates	Total (N=229)	Malignant (N=80)	Benign (N=149)	Chi-Square	P-Value	Odds Ratio	Lower 95%	Upper 95%
Poorly Defined Margins	94	42	52	2.6159	0.1058	1.79	0.88	3.62
Lobulated Appearance	169	57	112	2.7168	0.0993	0.58	0.31	1.11
Infiltrative Front	47	37	10	36.9214	<0.001	11.86	5.34	26.34

Conclusion

Parotid masses represent a diverse group of lesions with variable imaging characteristics. Our analysis revealed strong correlation between two characteristics (infiltrative front and poor margin definition) and malignancy. We would advocate for these grading characteristics to be used pre-operatively in counseling for potential malignancy. Of note, ACC and CPA showed better margin definition, which we hypothesize may be due to the indolent growth of acinic cell and the benign origin of carcinoma ex pleomorphic adenomas.

Zoomed EPI Diffusion Tensor Imaging of the Optic Nerve

Shah, P. N.·Covington, A.·Middleton, D.·Mohamed, F.
Temple University
Philadelphia, PA.

Purpose

The purpose of the study was to (a) image optic nerve (ON) in normal adults using a new zoomed DTI technique and (b) to optimize the DTI imaging parameters and provide a reliable method of DTI ON imaging for clinical use.

Materials & Methods

Twelve subjects (ages 25-50 years) without clinical evidence of ON pathology were recruited on a volunteer basis. All the subjects were instructed to fixate their eyes to a marker inside the 12-channel head coil during DTI scanning. Initially a sagittal scout T1 followed by conventional FSE T2-weighted scans of the orbit were obtained. A zoomed EPI technique DTI sequence was installed and optimized for imaging the optic nerve on a 3.0T Siemens Verio MR scanner. The following scan parameters were used to obtain high-resolution images of the orbits: 6 directions, b=800s/mm^2, voxel size=1.7x1.7x1.5 mm^3, axial slices=10, TR=6100-8000 ms, TE=94 ms, averages=16. This pulse sequence is based on a single shot echo planar (EPI) sequence with spatially selective 2D RF excitations. The data were transferred to an independent workstation for postprocessing. Tensor estimation was performed using MedINRIA software (www-sop.inria.fr/asclepios/software/MedINRIA/). Various DTI indices were calculated for ROIs drawn at every axial slice location along each individual ON: fractional anisotropy (FA), axial diffusivity (AD), radial diffusivity (RD), and mean diffusivity (MD) were measured. Each ON was located on the b0 image and a ROI was manually drawn on the corresponding FA map to include the middle portion of the ON verified by a board certified neuroradiologist.

Results

Imaging with the zoomed DTI sequence resulted in reliable DTI data of the ON (Figure 1). Qualitative examination of the images demonstrated reduced eddy current and motion distortions. A total of 23 ON were included in the data analysis. In one subject the ON on one side demonstrated severe distortion and hence not included in the analysis. Subjects showed mean ± standard deviation: FA=0.43±0.06, AD=1.04±0.22x10^{-3}mm^2/s,

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

RD=0.52±0.13x10^{-3} mm^2/s, MD=0.69±0.15x10^{-3} mm^2/s. The total scan time for DT imaging was under 5:30 min.

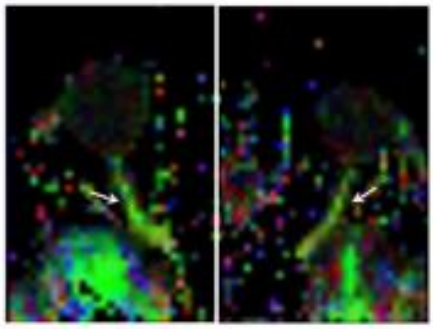

Figure 1: Fractional anisotropic images of the right and left optic nerve (white arrows) in a healthy volunteer using a zoomed DTI technique

Conclusion

This study demonstrates that reliable DT parameters of the optic nerve can be obtained in a reasonable time frame utilizing standard MR imaging equipment. Future studies with clinical pathology of the ON are warranted.

3T MR Characterization of the Optic Nerve Sheath in Astronauts

Hakimelahi, R.[1]·Riascos, R.[1]·Hasan, K. M.[2]·Heymann, J. C.[1]·Cotes, C. C.[1]·Sargsyan, A.[3]·Alperin, N.[4]·Kramer, L. A.[2]
[1]University of Texas Medical Branch, Galveston, TX, [2]University of Texas Medical School at Houston, Houston, TX, [3]Wyle, Houston, TX, [4]University of Miami, Miami, FL.

Purpose

Monitoring changes in the optic nerve (OND) and/or optic nerve sheath diameters (ONSD) on MR images has been used to evaluate patients with elevated intracranial pressure (EICP). We sought to compare and evaluate the physical dimensions of the optic nerve and the sheath in astronauts previously exposed to microgravity using 3T MRI with the assumption that exposure to microgravity can increase intracranial pressure due to cephalad fluid shift.

Materials & Methods

Twenty-seven astronauts (three females), with previous missions to the International Space Station (ISS) ranged between 14-382 days and who underwent MRI of the orbits between 2010 and 2012 were identified retrospectively. Fourteen astronauts were scanned before and after their most recent missions. The repeat scans were treated independently because of differences in microgravity exposure. In total, 40 scans (80 eyes) were evaluated. Seventeen astronauts were categorized as short-duration (< 30 days) and 23 as long-duration (≥30 days) based on cumulative microgravity exposure. The measurements were done 3 mm behind the fovea on axial and sagittal isovolumetric T2-3D-TSE sequences.

Results

No statistically significant difference was identified between the short and long mission groups in OND and ONSD of either eye. Both OND and ONSD were significantly longer in vertical directions than in the horizontal directions for both groups. A statistically significant difference between the axial and sagittal diameters also was observed in both eyes in the whole study population (p = 0.000) (Table 1).

Table 1. Comparison of axial and sagittal measurement in OND and ONSD.

	Axial	Sagittal	P Value
All OND Right	0.28 ± 0.01	0.31 ± 0.01	0.000
All ONSD Right	0.67 ± 0.02	0.70 ± 0.02	0.000
All OND Left	0.29 ± 0.01	0.32 ± 0.01	0.000
All ONSD Left	0.65 ± 0.01	0.69 ± 0.01	0.000
Short-Duration Microgravity Exposure OND Right	0.27 ± 0.01	0.30 ± 0.01	0.003
Short-Duration Microgravity Exposure ONSD Right	0.64 ± 0.02	0.67 ± 0.02	0.021
Short-Duration Microgravity Exposure OND Left	0.64 ± 0.02	0.32 ± 0.01	0.000
Short-Duration Microgravity Exposure ONSD Left	0.66 ± 0.02	0.71 ± 0.02	0.000
Long-Duration Microgravity Exposure OND Right	0.29 ± 0.01	0.32 ± 0.02	0.026
Long-Duration Microgravity Exposure ONSD Right	0.69 ± 0.03	0.72 ± 0.03	0.000
Long-Duration Microgravity Exposure OND Left	0.29 ± 0.01	0.31 ± 0.01	0.010
Long-Duration Microgravity Exposure ONSD Left	0.65 ± 0.02	0.67 ± 0.02	0.001

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Conclusion
These findings suggest a slightly elliptically shaped optic nerve/sheath in this population which theoretically could also be seen in other patient populations with different degrees of EICP. If this were found to be correct, it would be advisable to measure the optic nerve/sheath on coronal images. Shape of the nerve can be identified easily on the coronal views and both axial and sagittal diameters can be measured on the same slice to identify the largest diameter. We did not find any significant difference in OND or ONSD between the astronauts with short-duration and long-duration microgravity exposure. This might be due to a small sample size and consequent low statistical power.

Diffusivity of Intraorbital Malignant Lymphoma versus IgG4-Related Disease: 3D Turbo Field Echo with Diffusion-Sensitized Driven Equilibrium Preparation Technique

Hiwatashi, A.[1]·Yoshiura, T.[1]·Togao, O.[1]·Yamashita, K.[1]·Kikuchi, K.[1]·Honda, H.[1]·Obara, M.[2]
[1]Kyushu University, Fukuoka, JAPAN, [2]Philips Electronics Japan, Tokyo, JAPAN.

Purpose
It is difficult to evaluate diffusivity of the intraorbital structures using echo planar (EP) imaging. 3D turbo field echo with diffusion-sensitized driven-equilibrium preparation (DSDE TFE) is a novel non-EP technique for diffusion-weighted imaging (DWI). The purpose of this study was to differentiate intraorbital malignant lymphoma (ML) from IgG4 related disease (IgG4-RD) using the apparent diffusion coefficient (ADC) derived from DSDE TFE.
Materials & Methods
Fifteen patients with ML and eight with IgG4-RDs were imaged with DSDE TFE. Motion probing gradients were conducted at one direction (A-P) with b values of 0 and 500 s/mm^2. The imaging voxel size was 1.5x1.5x1.5 mm^3. Apparent diffusion coefficient was measured in the lesions. Signal intensity compared to normal gray matter on T1-weighted images, fat suppressed T2-weighted images and fat suppressed postcontrast T1-weighted images also was measured. Statistical analyses were performed with Mann-Whitney U test.
Results
Intraorbital lesions were clearly visualized on DSDE TFE without obvious geometrical distortion. Apparent diffusion coefficient of ML (1.24 ± 0.50 x 10^{-3} mm^2/s; mean ± standard deviation) was significantly lower than that of IgG4-RD (1.67 ± 0.84 x 10^{-3} mm^2/s; P < 0.05). Conventional sequences could not separate ML from IgG4-RD (0.92 ± 0.18 versus 0.94 ± 0.21 on T1-weighted images, 0.92 ± 0.17 versus 0.95 ± 0.14 on T2-weighted images, and 2.03 ± 0.35 versus 2.30 ± 0.58 on postcontrast T1-weighted images, for ML and IgG4-RD, respectively; P > 0.05).

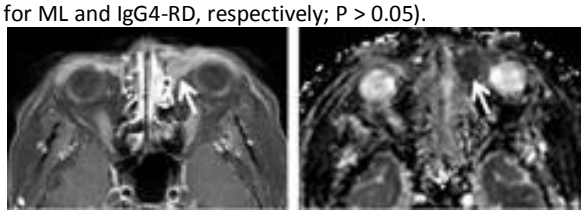

Figure: A 69-year-old male with lymphoma. Postcontrast fat-suppressed T1WI shows enhancing lesion in the left epicanthus (left, arrow). Apparent diffusion coefficient map shows restricted diffusion in the lesion (right, arrow).
Conclusion
Apparent diffusion coefficient derived from DSDE TFE help differentiate ML from IgG4-RD.

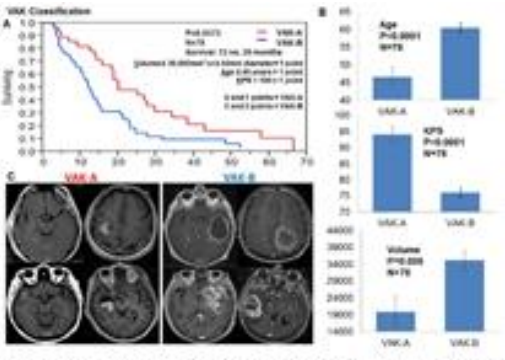
A Novel MR Imaging-Based Prognostic Classification Identifies Distinct Molecular Subgroups in Glioblastoma Multiforme

Colen, R. R.[1]·Mahajan, B.[2]·Sathyan, P.[1]·Kumar, A. J.[1]·Majumder, S.[1]·Hegi, M.[3]·Zinn, P. O.[4]
[1]M. D. Anderson Cancer Center, Houston, TX, [2]Brigham and Women's Hospital, Boston, MA, [3]University of Lausanne, Lausanne Switzerland, SWITZERLAND, [4]Baylor College of Medicine, Houston, TX.

Purpose
Several studies have established glioblastoma multiforme (GBM) prognostic and predictive models based on age, Karnofsky Performance Status (KPS), extent of resection, MGMT methylation, CIMP or IDH1 status. However, these parameters either have little connection to the underlying tumor biology and/or can only be determined by invasive measures. Thus, we present a novel clinically relevant imaging-genomic GBM classification based on tumor volume, patient age, and KPS (VAK) that can be determined upon patient admission.
Materials & Methods
We quantitatively analyzed the volumes of 78 GBM patient MRIs present in The Cancer Imaging Archive (TCIA) corresponding to patients in The Cancer Genome Atlas (TCGA) with VAK annotation. The variables then were combined using a simple 3-point scoring system to form the VAK classification. A validation set (N = 64) from both the TCGA and Rembrandt databases was used to confirm the classification.
Results
The image-based VAK-A and VAK-B classes showed significant median survival differences in discovery (P = 0.007) and validation sets (P = 0.008). A molecular gene signature comprised of a total of 25 genes and microRNAs was significantly associated with the classes and predicted survival in an independent validation set (P = 0.001). A

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

favorable MGMT promoter methylation status resulted in a 10.5 months additional survival benefit for VAK-A compared to VAK-B patients.



Volume, Age, KPS (VAK)- A and B classes showing **(A)** Kaplan Meier survival plot **(B)** Mean volume, Age, and KPS in VAK-A and VAK-B classes and **(C)** representative MRI images for VAK-A and VAK-B patients.

Conclusion

The noninvasive, image inclusive VAK classification with its implication of VAK-specific molecular regulatory networks, can serve as a very robust initial prognostic tool, clinical trial selection criteria, and important step toward the refinement of personalized therapy for GBM patients. A highly prognostic and predictive imaging genomic GBM classification that implies distinct genomic and possibly targetable molecular pathways can be a major advancement in personalized therapy.

Accuracy of a Multinomial Logistic Regression Model in Identifying Parathyroid Adenoma on 4D CT

Hito, R.[1]·Kelly, H. R.[1]·Ginat, D. T.[1]·Hamberg, L. M.[2]·Hunter, G. J.[1]

[1]Massachusetts General Hospital, Boston, MA, [2]Brigham and Women's Hospital, Boston, MA.

Purpose

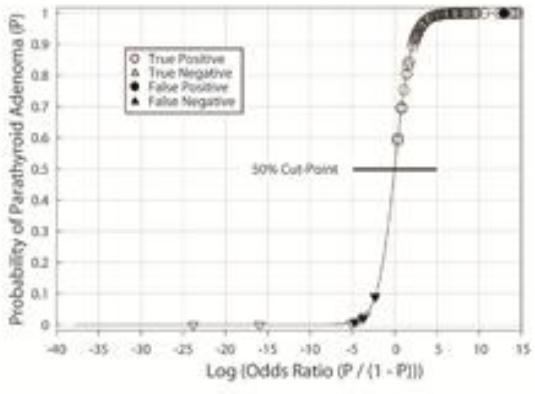
To investigate the accuracy of a 3-covariate multinomial logistic regression model in discriminating between parathyroid adenoma and nonadenomatous tissues as seen on presurgical localization scans using 4-dimensional computed tomography (4D CT).

Materials & Methods

Informed consent was waived by the institutional review body for this chart review study. From January through November 2012 there were 125 patients with biochemically documented hyperparathyroidism who underwent three-phase, contrast-enhanced 4D CT. Thirty-two did not proceed to surgery. Twenty were from outside institutions and follow-up information was not available. In the remaining 73 (13 men, 60 women: mean ages 61 and 61.3 years, respectively) surgical records were reviewed and the site(s) of the removed tissue identified. Using these locations as reference data, regions of interest (ROIs) were placed on these tissues on the 4D CT images. Hounsfield unit (HU) values from the ROIs were entered into an Excel worksheet where the probability that the surgically removed tissue was parathyroid adenoma was calculated using the logistic regression model, previously defined in an independent patient cohort. Probabilities over 50% were taken to mean parathyroid adenoma. The accuracy, sensitivity and positive predictive values of the model for identifying parathyroid adenoma were determined.

Results

There were 83 potentially abnormal surgical samples collected from 73 patients. Pathology identified 77 parathyroid adenomas and six thyroid lesions. The logistic regression model predicted 75 parathyroid adenomas. Seventy-four were correctly classified (true positive) and one was misclassified by the model (false positive). The model classified three true parathyroid adenomas as thyroid (n = 1) or lymph node (n = 2) (false negative). The remaining five lesions were classified correctly by the model as not parathyroid tissue (true negative). The accuracy, sensitivity and positive predictive values for the model were 95.2, 96.1 and 98.7 % respectively. Figure 1 demonstrates the distribution of the data along the model curve.



Conclusion

A 3-covariate multinomial logistic regression model using HU values from a three phase 4D CT scan protocol demonstrates that utilization of this model can allow for parathyroid tissue to be reliably discriminated from local mimics with high sensitivity and positive predictive value. Vascular thyroid nodules may behave indistinguishably from parathyroid adenoma and their interpretation remains challenging. Cystic parathyroid lesions and small lesions in regions of the scan that are noisy also may be challenging and application of the model under these circumstances must be performed cautiously.

Imaging-Genomic Necrosis Mapping Reveals Gender-Specific Survival and Molecular Determinants in Glioblastoma Multiforme

Colen, R. R.[1]·Changlai, T.[1]·Sathyan, P.[1]·Gutman, D.[2]·Zinn, P. O.[3]
[1]M. D. Anderson Cancer Center, Houston, TX, [2]Emory University, Atlanta, GA, [3]Baylor College of Medicine, Houston, TX.

Purpose
Despite recent discoveries of new molecular targets and pathways, the search for an effective therapy for glioblastoma (GBM) continues. A newly emerged field, imaging genomics, links gene expression profiles with MRI phenotypes. Cell death in GBM can either be associated with tumor suppressor or oncogenes, since increased cell death can be caused by an aggressive cellular growth (lack of oxygen/nutrients) or by the presence of tumor suppressor genes inducing apoptosis. Thus, an imaging genomic necrosis screen has the potential to uncover novel molecular determinants of cell death in GBMs. Here, we present the first comprehensive radiogenomic analysis using quantitative necrosis MRI volumetrics and large-scale gene- and microRNA expression profiling in GBM.
Materials & Methods
Based on The Cancer Genome Atlas (TCGA) and The Cancer Imaging Archive (TCIA) gene, microRNA, and quantitative MR imaging data sets were created in 78 patients. Top concordant genes and microRNAs correlated with high necrosis volumes were further analyzed using Ingenuity Pathway Analysis and cognate microRNA-gene networks created.
Results
Female patients demonstrated significantly lower volumes of necrosis than male patients. Thus, a gender specific analysis was chosen and revealed that female patients with high necrosis had a significantly shorter survival compared to both females with lower necrosis or males with high necrosis, while survival in males was similar in patients with high versus low tumor necrosis. The genomic analysis revealed that predominantly oncogenic pathways were associated with necrosis in female patients, while male patients showed a strong association with tumor suppressor pathways, while gender independent necrosis pathways showed equal distribution of both tumor suppressors and oncogenes.
Conclusion
Here, we propose a novel diagnostic method to screen for molecular correlates of necrosis in GBM. Our findings have potential therapeutic significance since the understanding of cell death molecular gene and microRNA signatures can improve therapy and patient survival in GBM.

A New Simplified CT-Guided Approach for Greater Occipital Nerve Infiltration in the Management of Arnold's Neuralgia: Preliminary Results in Twenty-One Procedures

Kastler, A.[1,2]·Onana, Y.[3]·Aubry, S.[3,2]·Kastler, B.[3,2]
[1]University Hospital, Clermont Ferrand, FRANCE, [2]I4S Laboratory EA 4268, Franche Comte University, FRANCE, [3]University Hospital, Besançon, FRANCE.

Purpose
To evaluate the efficacy of a new simplified CT-guided approach in the management of greater occipital nerve infiltration.
Materials & Methods
A total of 17 patients (five men, 17 women, with a mean age of 45 years) who underwent 21 procedures were included in this retrospective study between March 2012 and November 2012. All included patients suffered from severe greater occipital nerve neuralgia refractory to conventional specific treatments. Procedures were performed under CT guidance and local anesthesia. Initial nonenhanced planning CT was performed from C0 to C2. Infiltration of greater occipital nerve was performed exclusively at the most superficial site at the first bend of the GON between inferior obliquus capitis and semispinalis capitis muscles facing C1-C2 level, using a 22G needle. A mixture of fast- and slow-acting anesthetic (1.5 mL lidocaine hydrochloride 1% and 3 mL ropivacain hydrochloride 0.25%) then was injected followed by the injection of 1.5 ml of cortivazol at predefined target site. Pain was evaluated on VAS scores immediately before and after procedure and on a monthly basis following procedure. Technical success was defined by the ability to accurately position needle tip at target site. Clinical success was defined by pain relief greater than or equal to 50% lasting for at least one month.
Results
Mean pain prior procedure was 7.65/10. Patients suffered from unilateral pain in 13 of 17 cases (right, n = 7, left, n = 6) and bilateral pain in four cases. Technical success of procedure was 100%. Mean procedure time was 10-15 minutes. Clinical success rate was 86% (18/21 procedures, 2/17 patients). In case of clinical success, mean pain relief duration following procedure was 3.25 months (1-6 months).
Conclusion
This novel simplified CT-guided infiltration approach appears to be effective in the management of refractory Arnold's neuralgia. With this new technique, infiltration of the GON is safer, faster and technically easier compared to other previously described techniques.

KEYWORDS: Infiltration, CT, Headache, Arnold Neuralgia

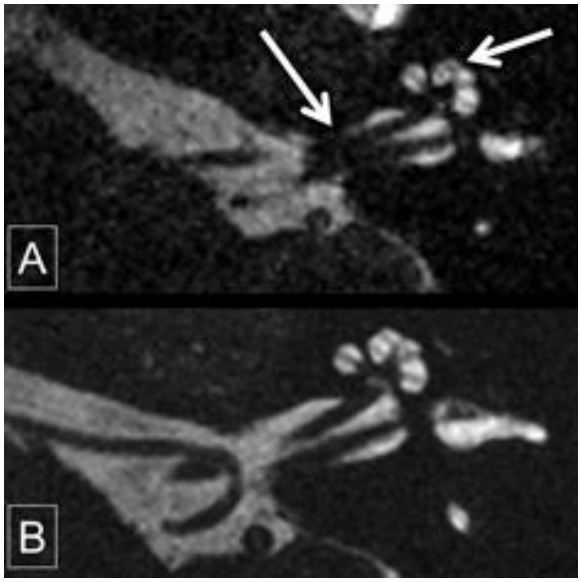
Reducing Banding Artifact in Balanced Steady-State Free Precession MR Imaging of the Inner Ear Using a Novel Shim Cycling Technique

Abele, T. A.·Kim, S. E.·Roberts, J. A.·Hadley, J. R.·Parker, D. L.·Wiggins, R. H.
University of Utah
Salt Lake City, UT.

Purpose
Balanced steady-state free precession (bSSFP) magnetic resonance (MR) imaging provides high-resolution cisternographic evaluation of the cerebellopontine angle/internal auditory canal (CPA/IAC) and inner ear but is limited by banding artifact associated with variations in the main magnetic field. Inner ear imaging with bSSFP is especially prone to banding artifact given the long TR required for high resolution and magnetic susceptibility related to the surrounding temporal bone. We have developed a novel shim cycling technique that reduces 3D bSSFP banding artifact by combining multiple image volumes acquired with different shim currents to create a uniform composite volume. The purpose of this study is to demonstrate marked reduction in banding artifact using our shim cycling technique in high-resolution 3D bSSFP imaging of the inner ear.
Materials & Methods
MR imaging of the inner ears of a healthy human volunteer was performed on a Siemens 3T TIM Trio using a custom built 4-channel coil (2 channels overlying each external ear). After initial adjustment of the volume shims, transmit voltage, and center frequency, seven 3D bSSFP (TrueFISP) image volumes were acquired. Between each volume acquisition the x-shim was altered, so that successive sets of images had different banding artifact locations. 3D bSSFP parameters were: TE/TR=3.4/6.8 ms, FA=50 degrees, FOV=160 x 160 mm2, matrix = 384 x 384 x 48, total scan time=14 minutes. Acquisition voxel dimension was 0.4 mm isotropic and displayed as 0.2 mm isotropic after zero-filled interpolation. To create the composite volume a median filter was applied along the shim steps with a width equal to the number of shim cycling volumes.
Results
Standard 3D bSSFP images demonstrated banding artifact in the apical turn of the cochlea and anterior wall of the internal auditory canal (arrows, Figure A). Shim cycled 3D bSSFP images (Figure B) at a similar plane showed marked reduction in banding artifact with improved delineation of the osseous architecture of the cochlea, cochlear and vestibular nerves, and anterior inferior cerebellar artery within the CPA/IAC.



Conclusion
Preliminary results demonstrate that composite shim cycled 3D bSSFP has markedly reduced banding artifact compared to a standard 3D bSSFP sequence. This technique has potential to significantly improve CPA/IAC and inner ear imaging with better detection of vestibular schwannomas and vascular loops, advanced characterization of inner ear microstructure, and reduced pseudolesions related to banding artifact. Future directions include comparison to other artifact reduction techniques and prospective evaluation of inner ear pathology.

KEYWORDS: Inner ear, MR imaging, banding artifact

eP-135

Quantitative Volumetric Analysis of Venous and Lymphatic Malformations of the Head and Neck to Assess Response to Percutaneous Sclerotherapy

Alexander, M. D.[1]·McTaggart, R. A.[2]·Choudhri, O. A.[2]·Wu, A.[3]·Ross, M.[4]·Do, H. M.[2]
[1]Santa Clara Valley Medical Center, San Jose, CA, [2]Stanford University School of Medicine, Stanford, CA, [3]New York University, New York City, NY, [4]George Washington University, Washington, DC.

Purpose
Percutaneous sclerotherapy is used widely to treat venous and lymphatic malformations, but no superior sclerosant has been identified. Studies evaluating efficacy of various sclerosants have relied heavily on qualitative and subjective measures such as cosmetic changes and patient satisfaction. This study describes and evaluates a novel quantitative technique for the evaluation of these lesions that may be employed in future research to define the best treatment agents.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Materials & Methods
Prospectively maintained procedure records were queried retrospectively to identify all patients with vascular malformations who underwent percutaneous sclerotherapy in the interventional neuroradiology department of a major academic medical center. Lesions were characterized as venous or lymphatic malformations according to the Mulliken and Glowacki classification. Medical records and images were reviewed to record demographic information, clinical and imaging characteristics of the lesions, all treatment sessions and modalities, and clinical response. Initial diagnostic and clinical data were used to classify lesion size by apparent size and degree of visible asymmetry due to the lesion. Size was categorized as not visible, small, medium, or large. Most recent clinical outcome was categorized as excellent, good, fair, or poor in keeping with previously reported classification schemes. Lesion volume was calculated using T2-weighted images for all available studies using Aquarius iNtuition version 4.4.6 (Terarecon, Foster City, CA). Due to a broad spectrum of patient age, volumes were normalized by body mass at time of diagnosis. Additionally, macrocystic and microcystic components of lesions were measured. Pearson coefficients (rho) were calculated to identify correlation between clinical and volumetric measures. Student's *t*-tests were performed to compare dichotomized groups based on lesion characteristics.
Results
Thirty-five patients were identified, undergoing a total of 75 sessions of percutaneous sclerotherapy. At the time of analysis complete records were available for review of 70 such interventions. Analysis of initial volumetric data compared to clinical measures was possible for 30 patients, and this yielded statistically significant correlation (rho = 0.359, p = 0.036). In those patients for whom data were available, an inverse correlation was found between initial lesion volume and qualitative clinical response to treatment (rho = -0.493, p = 0.027).
Conclusion
Previous research into percutaneous sclerotherapy for venous and lymphatic malformations of the head and neck has relied almost exclusively on qualitative clinical measures. The current study demonstrates the feasibility of volumetric analysis of such lesions based on magnetic resonance images. A significant correlation was seen between initial volumetric data and clinical measures of lesion size. The volumetric analysis also demonstrated an inverse correlation between initial lesion volume and clinical response to treatment. As further comparisons of various sclerosants are conducted to determine which agent is most effective, quantitative methods such as those described in this study should be utilized in addition to qualitative clinical results.

Incidental Thyroid Nodules on CT: Evaluation of Risk Categorization Methods for Workup of Nodules

Nguyen, X. V.[1,2]·Roy Choudhury, K.[1]·Eastwood, J. D.[1]·Lyman, G. H.[1]·Esclamado, R. M.[1]·Werner, J. D.[1]·Hoang, J. K.[1]
[1]Duke University Medical Center, Durham, NC, [2]The Ohio State University Wexner Medical Center, Columbus, OH.

Purpose
Thyroid nodules are common incidental findings on CT, but there are no clear guidelines regarding their further diagnostic workup. This study compares the performance of two risk categorization methods of selecting CT-detected incidental thyroid nodules (ITN) for workup.
Materials & Methods
The two categorization methods were Method A, which was based on nodule size ≥10 mm, and Method B, which was a three-tiered system based on aggressive imaging features, age <35 years and size ≥15 mm. In Part 1, the two categorization methods were applied to thyroid cancers in the National Cancer Institute's SEER database to compare the cancer capture rates and survival. In Part 2, 755 CT neck scans at our institution were reviewed retrospectively for the presence of ITNs ≥5 mm, and the same two categorization methods were applied to the CT cases to compare the number of patients that would theoretically meet criteria for workup. Comparisons of proportions of subjects captured under Methods A and B were made using McNemar's test.
Results
For 84,720 subjects in the SEER database, Methods A and B each captured 74% (62,708/84,720 and 62,586/84,720, respectively) of malignancies. SEER subjects that would not have met criteria for further workup by both methods had equally excellent 10-year cause-specific and relative survival of >99%. For Part 2, the prevalence of ITN ≥5 mm at our institution was 133/755 (18%). The number of ITN that would be recommended for workup by Method A was 57/133 (43%) compared to 31/133 (23%) for Method B ($p<0.0005$).
Conclusion
Compared to using a 10-mm size cutoff, the 3-tiered risk stratification method identifies fewer ITN for workup but captures the same proportion of cancers in a national database and shows no difference in missing high-mortality cancers.

Applying the Society of Radiologists in Ultrasound Recommendations for FNA of Thyroid Nodules: Effect on Workup, Malignancy Detection and Costs

Hobbs, H. A.·Bahl, M.·Nelson, R. C.·Eastwood, J. D.·Esclamado, R. M.·Hoang, J. K.
Duke University
Durham, NC.

Purpose
The Society of Radiologists in Ultrasound (SRU) developed sonographic recommendations for thyroid nodules that should undergo FNA. The intention of the guidelines was not to diagnose all cancer, but to diagnose "clinically significant " cancers while avoiding unnecessary tests and surgery in patients with benign nodules. The goal of this study was to determine the tests and surgeries that could be saved and the malignancies that would be missed if thyroid biopsies were performed according to SRU recommendations. A secondary aim was to estimate costs saved if SRU recommendations were utilized.
Materials & Methods
This is a retrospective study of 400 consecutive ultrasound-guided thyroid FNA encounters from July 2010 to June 2011. All nodules receiving biopsy were categorized as SRU positive (SRU+) or negative (SRU-) based on the sonographic findings. The SRU recommendations include solid nodules ≥15 mm, nodules with microcalcifications ≥10 mm, coarse calcifications ≥15 mm, and solid-cystic component ≥20 mm. Medical records were reviewed for pathology and management. Pathology was defined by surgical pathology result if available and FNA cytopathology if the patient did not have surgery. All malignancies were confirmed at surgery and were further followed for stage of disease, treatment response and overall survival. Cost estimates for SRU- patients were based on the reimbursement fee for procedural and pathology CPT codes according to 2012 Medicare Reimbursement Schedule.
Results
Four hundred biopsy encounters were for 390 patients and 560 nodules. Table 1 shows the final pathology results and management for SRU+ and SRU- groups. SRU- group represented 87/400 (21%) biopsy encounters and included five surgical resections for benign disease. Malignancy rate in the SRU+ and SRU- groups was 9% and 6%, respectively. All SRU- malignancies were localized papillary carcinomas ≤14 mm. The SRU+ group included 22 malignancies with mean size of 2.9 cm and 17 cases of regional disease. There were no tumor recurrence or deaths in the study period. The total healthcare cost estimate over a 12-month period for SRU- patients with benign disease was $89,188 (biopsy $64,728, surgery $24,460).
Table 1. Categorization of biopsies, pathology and treatment for SRU positive and SRU negative encounters.

	SRU positive	SRU negative	Total
Biopsy episodes/encounters	313	87	400
Biopsy episodes with benign results	245	82	327
Thyroid carcinoma total	22	5	27
Localized	17	5	22
Regional	4	0	4
Metastatic	0	0	
Malignancy – other type	1	0	1
Resection for benign disease	58	5	63
Follow-up imaging for nodule surveillance	85	35	120

Conclusion
Utilizing SRU recommendations would reduce the number of thyroid FNA encounters by 21% and prevent five surgical procedures for benign disease, resulting in a savings of over $89,000 for workup of benign disease. Although there were missed malignancies in the SRU- group, they were not aggressive by histological type, size and stage. Society of Radiologists in Ultrasound recommendations captured all malignancies that were larger and/or with metastatic disease.

18F Fluorodeoxyglucose Positron Emission Tomographic CT in the Evaluation of Residual/Recurrent Squamous Cell Carcinoma of the Oral Cavity and Oropharynx

Spampinato, M.·Matheus, M.·McLaughlin, C.·Kereshi, B.·Day, T.·Rumboldt, Z.
Medical University of South Carolina
Charleston, SC.

Purpose
Our goal was to assess the use of [18F] fluorodeoxyglucose positron emission tomographic CT (PET CT) in the assessment of recurrent or residual loco-regional disease in patients with previously treated oral cavity and oropharyngeal squamous cell carcinoma, with the hypothesis that maximal SUV measurements of the primary tumor site would be predictors of overall survival.
Materials & Methods

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

We retrospectively reviewed records of 64 patients referred for PET CT imaging to evaluate for residual or recurrent cancer of the oral cavity and oropharynx over a two-year period [42 men, 57 Caucasian, 7 African American, median age 61 (range 27-82)]. After PET CT all patients either underwent a biopsy of the primary tumor site or had routine clinical followup of at least 12 months. Imaging data collection was conducted by two observers and discrepancies were resolved by consensus. Maximal SUV were recorded for the primary tumor site. Overall survival in days was recorded. Differences in SUV measurements and clinical characteristics between patients with and without disease recurrence were evaluated using Mann-Whitney and Pearson chi-square tests. Receiver operating characteristic (ROC) analysis provided potential cut-off values for identification of tumor recurrence. Subsequently, Kaplan-Meier survival curves also were generated for the dichotomized maximal tumor SUV values, based on the results of the ROC analysis. Results were considered statistically significant when $p < 0.05$.

Results

There were no significant differences between subjects with and without recurrent disease in gender ($p = 0.179$), racial distribution ($p = 0.684$), ethanol abuse ($p = 0.177$), history of smoking ($p = 0.503$), initial cancer staging (0.924), and age ($p = 0.137$). As expected, survival was significantly worse in patients with recurrent disease ($p < 0.001$). Maximal primary tumor site SUVs were significantly different between pathology-proven recurrent tumors and cases without disease at pathology or clinical followup ($p = 0.001$). The area under the ROC curve for maximal primary tumor site SUV was 0.74 (95% confidence interval: 0.60 - 0.88, $p = 0.001$). Thresholds of 4.3 and 4.5 for maximal primary tumor site SUV provided the best combination of sensitivity, specificity and accuracy for this parameter (respectively 80%, 51%, 70% and 76%, 55%, 70%). The Kaplan Meier analysis showed that maximal tumor SUV values > 4.3 and maximal tumor SUV values > 4.5 were significant predictors of overall survival (respectively chi square =13.40, $p < 0.001$; chi square =12.19, $p < 0.001$)

Conclusion

Quantitative SUV measurements and in particular maximal primary tumor site SUV can be a useful adjunct to the interpretation of [18F] PET CT studies in the detection of residual/recurrent disease and in predicting survival in squaumous cell carcinoma of the oral cavity and oropharynx.

MR Perfusion Findings in Head and Neck Masses

Aralasmak, A.·Yetis, H.·Yıldız, S.·Meric, A.·Pinarbasili, N.·Toprak, H.·Alkan, A.
Bezmialem Vakif University
Fatih/Istanbul, TURKEY.

Purpose

To define MR perfusion findings of head and neck masses.

Materials & Methods

Total 48 patients, referred to MR unit for head and neck imaging for mass lesion, were enrolled. T2 dynamic contrast-enhanced MR perfusion sequences were added following routine noncontract views, thereafter contrast-enhanced sequences of the neck region were completed. For MR perfusion, routine dose of gadolinium (0.1 mmol/kg body weight) was administrated after 7sn of data acquisition. The injection was performed by automatic injector in the right arm at a rate of 5 ml/s followed by 15 ml saline. During the postprocessing, vertebral arteries were chosen for reference artery. Following computation of CBV, CBF, MTT and TTP maps, measurements were performed from solid and mostly enhancing and hyperperfused part of the mass lesions. At the same slice, measurements from normal-appearing muscles also were measured. Normalized CBV (nCBV), CBF (nCBF), MTT (nMTT), and TTP (nTTP) values were calculated by dividing the perfusion values of the mass lesions to that of the skeletal muscles. Except three, pathology results of all were obtained and correlated with nCBV, nCBF, nMTT, nTTP values. Lymphadenopathies were accepted as mass lesions and grouped according to their pathology.

Results

Table shows the neck masses, their pathology results and their nCBV, nCBF, nMTT, nTTP values.

Head and Neck Masses	Number	nCBV	nCBF	nMTT	mTTP
Ectopic Thyroid Tissue	2	50.7	20.6	3.03	10.28
Squmaous Cell Cancer	10	45.15	16.03	3.25	1.17
Papillary Thyroid cancer	4	35.43	26.99	4.02	3.58
Glomus tumor	4	25.5	13	5.52	4.5
Parotid Warthin Tumor	1	22.82	19.08	2.3	1.52
Reactive Lymph node Hyperplasia	2	21.69	9.26	1.52	1.28
Parotid Myoepithelial Carcinoma	1	12.31	7.06	1.81	1.44
Granulamatous Lymphadenitis	3	7.39	6.71	1.72	2.16
Lymphoma	9	6.85	7.59	4.09	1.15
Giant Multinoduler Goiter	3	6.58	3.91	9.59	1.34
Sebaceous Carcinoma	1	3.72	19	1.45	1.69
Parathyroid Carcinoma	1	1.51	1.35	0.79	0.99
Lipoma	2	1.84	2.23	0.57	1.16
Venolymphatic malformation	1	0.58	50	1.07	0.98
Mucocele	1	0	0	0	0

Conclusion

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

MR perfusion studies with conventional head and neck MR imaging will be helpful for characterization of head and neck masses. Ectopic thyroid masses, SCCs, papillary thyroid cancers and glomus tumors were well hyperperfused masses of neck region. Lymphomas usually were hypoperfused masses. Although we observed some SCC masses as minimally hyperperfused and some lymphoma masses as hyperperfused in our study. Granulomatous lymph nodes were usually hypoperfused compared to the reactive lymph nodes. Warthin and myopeithelial carcinoma of parotid gland were both hyperperfused masses. Giant multinoduler goiters were observed hypoperfused, although they are enhancing avidly on postcontrast views.

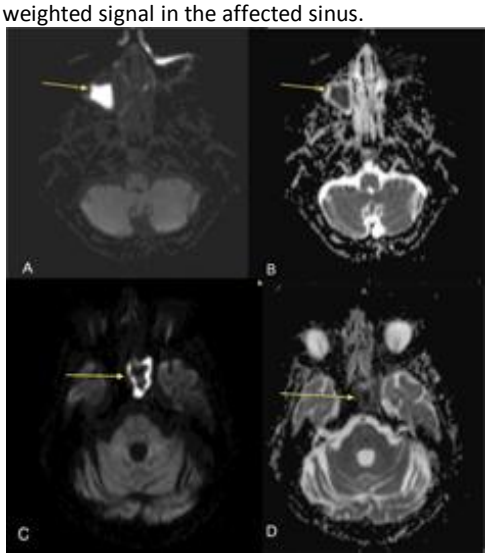
Diffusion Restriction in the Paranasal Sinuses: Clinical and Computed Tomographic Correlation

Besachio, D. A.·Rassner, U.
University of Utah
Salt Lake City, UT.

Purpose
To identify any clinical significance of diffusion restriction in the paranasal sinuses seen on brain magnetic resonance imaging (MRI).
Materials & Methods
Brain MRI imaging interpreted by a single neuroradiologist over a one-year period was reviewed retrospectively. Diffusion restriction on DWI imaging was identified in the paranasal sinuses or nasal cavity in 29 patients. When computed tomography (CT) of the site demonstrating diffusion restriction was available, these findings were correlated with MRI findings. Any available clinical-pathologic correlation also was performed.
Results
The most commonly identified site of diffusion restriction is the maxillary sinus. We were able to correlate diffusion restriction with CT scan of the head, face or neck in 18 subjects performed within eight weeks of MRI. Thirteen of 18 (72%) demonstrated mucoperiosteal thickening on CT of the involved sinus wall. We identified two main patterns of diffusion restriction in the paranasal sinuses, central and mucosal. Although only three cases were seen, a mucosal pattern of diffusion restriction in the sphenoid sinus was noted with the diagnosis of invasive fungal sinusitis in two of three cases (66%). A single case of maxillary sinus mucosal diffusion restriction was present with a confirmed case of invasive fungal sinusitis. The single case of nasal cavity diffusion restriction demonstrated squamous cell carcinoma on follow-up resection of the associated soft tissue mass. Of note, no CT correlative cases demonstrated air-fluid levels, a finding often associated with acute sinusitis. T1- and T2-weighted imaging characteristics were variable but low or mixed low and intermediate T2 signal predominated (24/29) in areas of diffusion restriction, in concordance with previous literature. Of note, all cases of invasive fungal sinusitis and diffusion restriction were associated with high T1-weighted signal in the affected sinus.



Conclusion
Diffusion restriction in the paranasal sinuses is an uncommon finding on brain MRI but likely represents a finding worthy of mention. The most common pattern identified is central restriction, which appears to be strongly associated with changes seen in chronic inflammatory sinonasal disease. A mucosal pattern was less common and in the sphenoid sinus may be associated with mucosal necrosis secondary to invasive fungal sinusitis.

One Low-Radiation Exposure MDCT of the Sinuses Can Be Used for Both Clinical Diagnosis and Be of Adequate Quality to Provide Safe Navigational Guidance for Sinus Surgery

Siegelman, J. R. Q. W.[1]·Supanich, M.[2]·Magri, A.[3]·Lesnik, G. T.[1]·Green, S. J.[1]·Donovan, W.[1]
[1]William W Backus Hospital, Norwich, CT, [2]Henry Ford Hospital, Detroit, MI, [3]Upstate Medical Physics - Landauer, Victor, NY.

Purpose
Given the recent changes announced by the International Commission on Radiological Protection (ICRP) related to tissue reactions from low levels of ionizing radiation, and new lowered threshold for absorbed dose in lens of .5 Gy, institutional dose and radiation exposure levels for sinus computed tomography (CT) studies using automatic exposure control (AEC) were examined across one institution's three unique scanner models. In addition, the adequacy of institutional protocols for endoscopic sinus

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

surgical (FESS) surgical mapping was assessed. This work aims to assess radiation dose levels objectively. This research examines the use of $CTDI_{vol}$ and estimated organ dose.

Materials & Methods

Under IRB approval, retrospective radiation exposure levels and organ dose estimates from routine CT sinus studies using AEC on three volumetric MDCT scanners from three different manufacturers were carried out using a commercially available program eXposure ™. The software uses one phantom model from the Cristy set of models, and the UK National Radiation Protection Bureau (NRPB report R186) to complete the Monte Carlo simulation to estimate organ doses based on the area scanned and the scanner output. Mean organ dose of the lens and salivary glands were compared with the the scanner reported CTDI vol $_{vol}$, and DLP. Data from a total of 303 consecutive patients studies over a period of 10 months were identified for analysis. The same diagnostic scans also were utilized for surgical planning. The objective navigational ability of Functional Endoscopic Sinus Surgery software (Landmarx TM) for all 49 patients who underwent both sinus CT using these protocols was assessed.

Results

The data from the patient population was found to have a $CTDI_{vol}$ mean 11.8mSv, s.d. 2.1, lens dose 5.3mSv, sd 0.825, Salivary gland dose 8.5 mSv, sd 1.657. A linear relationship was found between $CTDI_{vol}$ and absorbed lens dose with a slope of 0.37 and a Pearson Correlation Coefficient of 0.92. The relationship between $CTDI_{vol}$ and the dose absorbed by the salivary glands was determined to have a linear relationship with a slope of 0.75 and a Pearson Correlation Coefficient of 0.93. FESS software was able to successfully navigate in all 49 of consecutive cases at our institution (n = 49).

Conclusion

Low radiation exposure MDCT, utilizing a radiation dose level, below the 25th percentile based on ACR Dose Index Registry for sinus CT and approaching radiation exposure levels obtained with cone beam CT, provides adequate anatomical detail for endoscopic sinus surgical navigation. Absorbed organ dose in sinus studies is provided utilizing the retrospective Monte Carlo simulation of absorbed organ doses from clinical CT studies and linear relationships between organ doses and $CTDI_{vol}$ were observed.

Oval Window Dysplasia: Developmental Dynamics and Imaging Correlate

Raz, E.[1]·Gupta, D.[1]·Gangadhar, K.[1]·Hagiwara, M.[1]·Som, P.[2]·Yu, E.[3]·Fatterpekar, G.[1]
[1]New York University, New York, NY, [2]Mount Sinai Hospital, New York, NY, [3]University of Toronto, Toronto, ON, CANADA.

Purpose

Recent genetic and embryologic studies have demonstrated that the development of oval window is intimately dependent on the development of stapes footplate and the normal course of the tympanic segment of the facial nerve. The purpose of our study was to provide an imaging correlate to the normal and abnormal embryogenesis of these structures by: 1. Assessing the presence and size of the oval window in individuals with normal stapes. 2. Assessing the presence and size of the oval window in patients with dysplastic or absent stapes. 3. Evaluating the course of the facial nerve through the tympanic cavity in “normal” individuals, and in patients with dysplastic stapes.

Materials & Methods

Fifteen patients with absent or dysplastic stapes were identified retrospectively by searching the hospital database and radiology reports. Of these, three patients demonstrated opacified middle ear cavities making it difficult to assess the stapes. These three patients were therefore excluded from the study. Twelve age-matched individuals with normal high-resolution CT studies of the temporal bone, obtained for trauma were included as the control population. The studies were assessed for presence of stapes and oval window, size of oval window, and course of the facial nerve through the tympanic cavity.

Results

In the control population, the stapes and oval window were identified in all 12 individuals. The oval window measured 2.3 + 0.2 cm (mean 2.4 cm) in the axial plane, and 1.5 + 0.2 cm (1.4 cm) in the coronal plane. In the patient population, the stapes was absent in 10 patients, and dysplastic in two patients. In all 10 patients, where the stapes was absent, the oval window was completely atretic. Instead a bony plate was seen in the expected location of the oval window. In the remaining two patients with dysplastic stapes, in terms of its morphology and orientation, the oval window was seen to be dysplastic, being smaller in size, measuring 0.8 - 1.0 cm in the axial plane, and 0.5 - 0.8 cm in the coronal plane. A normal course of the facial nerve was seen in all 12 normal temporal bone CT studies. Instead, an anomalous course of the facial nerve was seen in all 12 patients.

Conclusion

Our study conclusively shows that a normal stapes is essential for the presence of a normal window. Likewise, an absent/dysplastic stapes results in an absent/dysplastic oval window, and is associated with an anomalous course

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

of the tympanic segment of the facial nerve. These findings are consistent with recent embryologic and genetic studies which have demonstrated that the presence of oval window is largely dependent on induction signals from the stapes, and is influenced by the location of the facial nerve in the tympanic cavity.

KEYWORDS: Temporal bone, Dysplasia

Paragangliomas and the Jugular Vein

Orru', E.·Aygun, N.·Blitz, A. M.·Carey, J. P.·Olivi, A.·Yousem, D. M.
Johns Hopkins Medical Institution
Baltimore, MD.

Purpose
Paragangliomas are neuroendocrine tumors originating from the extra-adrenal paraganglia of the nervous system, and arise in the head and neck region (H&N) in three percent of cases. The most common pathologic entity in this area is carotid body tumor (CBT), followed by glomus jugulare (GJ) and jugular tympanicum (JT), while the rarest is glomus vagale (GV). Surgery is the only definitive treatment, tailored on a patient-by-patient basis depending on symptoms and location of the lesions. These tumors are known to often involve neighboring structures, either invading or compressing them. Our aim was to determine the incidence of jugular vein (JV) invasion or compression by paragangliomas and to determine which modality [computed tomography (CT), magnetic resonance imaging (MRI) or digital subtraction angiography (DSA)] was most accurate in making this determination.
Materials & Methods
This study was HIPAA compliant and approved by the institutional IRB. We retrospectively reviewed the records and imaging studies of all the patients with H&N paragangliomas identified in the past five years via a radiology information system keyword search. Imaging studies of 31 patients who underwent surgical treatment were reviewed and compared with surgical reports regarding JV involvement.
Results
The study group consisted of 19 (61.3%) females and 12 (38.7%) males with an average age of 48 years (range: 26-69 years). Of these patients 18 (58.0%) had GJ, seven (22.6%) had CBT, three (9.7%) had JT and three (9,7%) had GV. Eight (25.8%) tumors were recurrent. Overall, imaging studies identified JV involvement in 20 cases (64.5%), of which 16/31 (51.6%) showed JV invasion and four of 31 (12.9%) JV compression. Only GJs showed JV invasion. MR imaging was performed in 19 patients and gave positive results in 15 cases, showing sensitivity (Se) of 93%, specificity (Sp) of 60%, positive predictive value (PPV) of 87% and negative predictive value (NPV) of 75%; accuracy was 84%. CT was performed in 17 patients with eight positive results showing Se of 89%, Sp of 100%, PPV of 100% and NPV of 89%; accuracy was 94% . DSA for purposes of pre-operative embolization was carried out in 20 patients and positive in eight patients, showing Se of 54%, Sp of 86%, PPV of 88%, NPV of 50%; accuracy was 65%.
Conclusion
The JV is involved in 64.5% of cases of H&N paraganglioma. Wall invasion is characteristic of the GJs, while JV displacement can be present with other tumors. For the evaluation of the JV in the presurgical management of H&N paragangliomas, MRI has the highest Se while CT has the highest Sp. Digital subtraction angiography alone is not reliable in assessing the JV involvement, but is very rarely performed as the only imaging modality.

eP-144

Redefining Normal Facial Nerve Enhancement: Healthy Subject Comparison of Typical Enhancement Patterns, Postcontrast Spin Echo versus Magnetization Prepared Rapid Acquisition Gradient-Echo Imaging

Lubarsky, M.·Aiken, A. H.·Saindane, A.·Kang, J.·Hudgins, P. A.·Dehkharghani, S.
Emory University
Atlanta, GA.

Purpose
Normal facial nerve contrast enhancement patterns have been described on conventional T1-weighted spin echo (SE) sequences. However, they have not been described on the more recently introduced and commonly employed magnetization prepared rapid acquisition gradient echo (MPRAGE) sequences. Advantages of MPRAGE are near-isotropic volumetric images that allow multiplanar reformations and robust contrast. In this investigation we compare the pre vs. postcontrast features of cranial nerve VII of both SE and MPRAGE sequences in a 23-patient cohort.
Materials & Methods
In this prospective IRB-approved study, 23 patients with no facial nerve symptoms comprised the study population, and 38 normal nerves were reviewed (eight nerves were excluded due to presence of a mass). Pre and postcontrast signal intensity (SI) on SE and MPRAGE of seven facial nerve segments (cisternal, canalicular, labyrinthine, geniculate, superficial petrosal, tympanic, and stylomastoid) were assessed independently by two neuroradiologists, following consensus read of a subset of cases. Corresponding pre and postcontrast multiplanar data sets were analyzed synchronously; signal intensities for each segment were assigned a value of 0-3 (0-no signal; 1-faint visualization; 2-signal equivalent to normal brain; 3-signal equivalent to enhancing dural sinus), with

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

enhancement defined as the difference in signal intensity between pre and postcontrast images. Statistically significant differences in location and degree of SI and enhancement were assessed. Statistical significance was defined as a p-value:<0.05.
Results
1. Statistically significant higher precontrast SI was demonstrated in five segments (cisternal, canalicular, labyrinthine, geniculate and stylomastoid) on MPRAGE when compared to SE sequences. 2. Statistically significant higher postcontrast SI was demonstrated in cisternal, canalicular, labyrinthine, geniculate and superficial petrosal nerve segments on MPRAGE when compared to SE sequences. 3. In the SE series, statistically significant enhancement was demonstrated in labyrinthine, geniculate, superficial petrosal nerve, tympanic, and stylomastoid segments and lack of enhancement was demonstrated in cisternal and canalicular segments. 4. In the MPRAGE series, statistically significant enhancement was demonstrated in geniculate, superficial petrosal nerve, tympanic, and stylomastoid segments and lack of significant enhancement was demonstrated in cisternal, canalicular and labyrinthine segments.
Conclusion
Significantly greater facial nerve SI is observed on MPRAGE sequences, both with and without gadolinium administration among normal subjects in most facial nerve segments. Improved identification of the facial nerve and/or its circumneural plexus on MPRAGE is thus more likely, and may be misinterpreted as pathologic when evaluated in the context of existing paradigms of normal enhancement derived from past studies employing SE techniques. Postcontrast MPRAGE sequences may falsely suggest pathologic enhancement in intracanalicular or occasionally the cisternal segments, two segments that have been described as nonenhancing, likely due to the greater intrinsic SI of the nerve. True enhancement patterns differed only in the labyrinthine segments, seen only in SE, likely due to the insufficient resolution to identify the nerve/plexus on precontrast SE. As volumetric, high-resolution imaging becomes more commonplace, examiners should remain cognizant of normal deviation from expected "enhancement" patterns to avoid misdiagnosis and other interpretive pitfalls.

eP-145

Semicircular Canal Dehiscence in Children with Sensorineural Hearing Loss

Choudhri, A. F.[1,2]·Whitehead, M. T.[1,2]·MacDonald, C. B.[1]
[1]University of Tennessee Health Science Center, Memphis, TN, [2]Le Bonheur Children's Hospital, Memphis, TN.

Purpose
Imaging of sensorineural hearing loss (SNHL) often is performed with temporal bone CT, sometimes with MR and occasionally using both modalities; however many patients have no identifiable structural abnormality. An enlarged vestibular aqueduct is a commonly reported finding in children with SNHL; however the incidence of other communications between the labyrinthine system and the intracranial compartment is not known. We evaluated the incidence of dehiscence of the superior, lateral, and posterior semicircular canals (SSCC, LSCC, PSCC), respectively in children with SNHL.
Materials & Methods
One hundred consecutive temporal bone CT studies on children with SNHL were evaluated by two neuroradiologists. All studies were acquired volumetrically on a 320 detector CT scanner with 0.5 mm collimation. 0.5 mm axial source data were available for review in all cases, as well as 1 mm axial and coronal bone algorithm images. The osseous integrity of the semicircular canals was evaluated, as well as the morphology of the vestibule, cochlea, and the size of the vestibular aqueduct.
Results
There were 11 instances of semicircular canal dehiscence identified in eight patients, all of whom had normal size of the vestibular aqueduct and no CT evidence of cochlear dysplasia. This included seven PSCC, three SSCC, and one LSSC. Of the seven cases of PSCC dehiscence, three were only visible on the 0.5 mm images whereas four were visible on both 1.0 and 0.5 mm images. The cases of SSCC and LSSC dehiscence were visible on both data sets.
Conclusion
Semicircular canal dehiscence is not uncommon in children with SNHL, and may be related to SNHL by the same mechanisms as an enlarged vestibular aqueduct. Dehiscence of the PSCC may be easier to detect on source data as opposed to thicker sections. Close scrutiny of the vestibular system and semicircular canals, including use of thin-section data, may increase the diagnostic yield on CT of the temporal bone performed in children with SNHL.

KEYWORDS: Temporal bone, Hearing loss

Head and Neck Endovascular Repair of Vascular Malformations

Yakes, W. F.
Vascular Malformation Center
Englewood, CO.

Purpose
To determine the efficacy of ethanol embolotherapy of extracranial head and neck vascular formations of all types, particularly after failures of other endovascular and surgical treatments.
Materials & Methods
One hundred sixty-six patients (64 males, 102 females; mean age 38 years) presented with extracranial arteriovenous malformations (AVMs) of the head and neck area. Over half of the patients had undergone previously

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

failed therapies. All patients underwent ethanol embolotherapy under general anesthesia. Forty-five patients had AVMs and 121 patients had venous malformations (VM).
Results
Of 45 AVM patients, 26 patients are cured (mean followup 2½ years); of 121 venous malformation patients 65 are at end-therapy (mean followup 4½ years). The remaining patients are not at end-therapy and are being treated for their residual malformations. In AVM followup, arteriography is the main imaging modality to determine cure or residual AVM as MR is less sensitive in the evaluation of residual AVM. In VM followup, MR is the main imaging tool, particularly with T-2 fat suppression and/or STIR imaging. All patients demonstrated improvement post-therapy. Complications were 4.5%, to include bleeding self-limited partial 7th nerve palsy (with recovery), skin injury (not requiring skin grafts), infection and pain.
Conclusion
Ethanol has proven its consistent curative potential at long-term followup for high-flow AVMs and low-flow VM lesions at long-term followup as lesions in the periphery. Complication rates remain low. The procedures are tolerated well by the patients and done on an out-patient basis. Prior surgery and embolization procedures can cause difficulty in lesion access, but does not obviate further ethanol endovascular treatment.

Pipeline Embolization Device Strategies

Urdaneta-Moncada, A. R.[1]·Ziegler, J.[2]·Mowji, P.[3]·Feng, L.[1]·Chao, K.[1]
[1]Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA, [2]Kaiser Permanente San Diego Medical Center, San Diego, CA, [3]Kaiser Permanente Orange County Medical Center, Anaheim, CA.

Purpose
Pipeline embolization device (PED) is a flow diversion stent for the treatment of large wide-neck aneurysms that are not well treated with coiling methods including stent assisting coiling. The PED material and design are relatively unique including its deployment. Objective: Evaluation of the PED procedures including issues during deployment and strategies to outcome problems.
Materials & Methods
Retrospective multicentered case series of 30 PED procedures for treatment of aneurysms. The cases were evaluated for issues that arose during PED deployment. The different strategies for managing problems were assessed for their effectiveness.
Results
There were eight major issues with PED deployment. 1. Detachment from capture coil, 2. Pipeline embolization device apposition to the vessel wall, 3. Torqueing or twisting of the PED, 4. Accurate placement of the PED, 5. Herniation of PED into aneurysm, 6. Advancing the microcatheter and removing the delivery system, 7. Accessing the distal outflow artery, and 8. Postprocedure stroke within three days. Successful treatment strategies for each of the major issues demonstrated reasonable success.
Conclusion
Pipeline embolization device is a 1st generation flow diversion stent with a variety of issues related to its deployment. However, familiarity with PED deployment strategies can result in a more successful deployment.

Endovascular Treatment of Complex Intracranial Aneurysms: Flow Diverter Silk Stent

Buyukkaya, R.[1]·Cebeci, H.[2]·Erdogan, C.[2]·Hakyemez, B.[2]
[1]Duzce University, Duzce, TURKEY, [2]Uludağ University, Bursa, TURKEY.

Purpose
Endovascular treatment of intracranial cerebral aneurysms is different from classic saccular aneurysms when they are wide-necked, blister-like, fusiform-shaped and large size (more than 20 mm). Treatment of these aneurysms are more difficult and mortality and morbidity rates are higher. Flow diverter stents are designed specifically for

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

challenging aneursyms. They provide endovascular reconstruction in aneurysmal segment to induce cure. In this study flow diverter stent (Silk; BaltExtrusion) technique is used in the treatment of complex ruptured or unruptured aneurysms. Early and midterm results of treatment, technical approach, thromboembolic results and approach to ruptured aneurysms were evaluated.
Materials & Methods
Thirty-two patients [age range: 34-79 years; 23 female (71.8%), nine male (28.2%)], whose aneurysms were not eligible for conventional endovascular techniques or surgery, were treated with Silk stent. Forty Silk stents were placed in 34 aneurysms (32 radiologically and clinically diagnosed patients). Three of the aneurysms were ruptured anerysms. Twenty of the aneurysms were carotid-ophthalmic aneurysms (58.8%) and six were cavernous ICA aneurysms (17.6%). There were two supraclinoid aneurysms (5.9%), two petrosal ICA aneurysm (5.9%). There were only four posterior circulation aneurysms in our series (11.8%). Except for three patients (8.8%) who presented with subarachnoid hemorrhage, all patients were pretreated with dual antiplatelet medications for at least three days before intervention. Three patients who presented with subarachnoid hemorrhage were treated with dual antiplatelet medications at the time of intervention. All patients received antiplatelet medication at least for a three-month period after endovascular treatment.
Results
The Silk stents were placed in a proper position in all patients. Adjunctive therapies were performed in four (12%) patients. Intra-arterial abciximab was administered in two patients because of intra-arterial thromboembolic event and intrastent balloon modelling was done in two patients. There was one mortality (2.94%) and one transient morbidity (2.94%). Control angiographic studies were performed in 31 patients (one mortality) and 33 aneurysm at the mean time of 9 ± 3 months (3-15 mo) after treatment. Control angiographic results included 81.8% complete occlusion (27/33), 12.1% residual neck remnant (4/33) and 6.1% residual saccular filling (2/33).
Conclusion
Flow diverter Silk stent is an effective tool for endovascular treatment of ruptured and unruptured challenging aneurysms because it allows high total occlusion rates, it is safe and effective and has acceptable mortality and morbidity rates.

KEYWORDS: Aneursym, Flow diverter, silk stent

eP-149

Are 'AComs' "AComs"?

Hughes, N.·Shankar, J.
Dalhousie University
Halifax, NS, CANADA.

Purpose
In current literature, the term anterior communicating aneurysm (Acom) incorporates true anterior communicating artery, A1-A2 junction, A1 and A2 aneurysms. What proportion of Acoms are actually true Acoms?
Materials & Methods
We completed a retrospective imaging review of coiled Acom aneurysms in the Dalhousie neuroradiology department from January 1, 2007 to October 6, 2011 for a total of 57 patients. Of these, 47 had CT angiography (CTA) imaging available on the Nova Scotia PACS system. Only patients with CTA images were recategorized into one of the four subgroups. One patient's images were indeterminate. Classification was accomplished using 0.6, 1.5 or 2.5 mm axial source images with coronal and sagittal reconstructions.
Results
There were 39 A1-A2 junction aneurysms, four true Acom, two A2 and one with both A1-A2 and true Acom. Of the 40 A1-A2 junction aneurysms, 15 were males. Thirty-eight of the 46 presented with rupture. All of the eight elective coilings were A1-A2 aneurysms. For most of the aneurysms, the domes were projecting in two orientations, for example superior and anterior. The five true Acom aneurysms appeared to project in one plane, two superior, two inferior and one anterior.
Conclusion
The pathogenesis of the subgroups of Acom aneurysms is unclear and further research is needed. In our study, the vast majority of Acom aneurysms are A1-A2 junction aneurysms. Are these four subgroups, therefore, linked together inappropriately in the current literature?

Preliminary Results of Flow Diversion Device (Silk Stent) in the Treatment of Intracranial Aneurysms in Fifteen Subjects: Medium and Long-Term Followup

Morin, F.·La Piana, R.·Cortes, M.·Tampieri, D.
Montreal Neurological Institute
Montreal, QC, CANADA.

Purpose
Treated intracranial aneurysms have an approximately 30% rate of recanalization. In the last years, many technical advances, such as the balloon remodelling technique and stent-assisted coils, have improved the results obtainable with endovascular treatment. A new

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

generation of stents has been introduced recently: the flow diversion devices. They have been developed especially for the treatment of giant, fusiform or wide-neck aneurysms. Flow diverters reduce intra-aneurysmal blood flow and eventually thrombosis of the aneurysm is achieved. The SILK stent is a self-expandable flexible stent with low porosity; it was approved for clinical use in Europe in 2007. The aim of our study is to analyze the preliminary results at medium and long-term followup of our experience with SILK stent in a series of 15 consecutive cases.

Materials & Methods

The use of SILK stent as flow diverter was introduced at our Department of Neuroradiology in April 2009. Since then, a series of 15 patients with a total of 16 intracranial aneurysms were treated endovascularly using SILK stents. Thirteen patients were female and two were male, with a mean age at treatment of 53.7 years (range between 42 and 63 years of age). There were 13 aneurysms located in the anterior circulation, two in the basilar artery and one in the vertebral artery. Thirteen of these aneurysms were saccular and three were dissecting. Neuroradiologic followup [DSA, CTA (320 row scanner, Toshiba Aquilion ONE) or MRI/A] was available for 14 patients at three months (100%), 11 patients (77.3%) at 8-12 months and seven patients (46.7%) at two years.

Results

Twelve patients were treated using one SILK stent; of these, in one patient one SILK stent treated two aneurysms. In four patients two SILK stents were required in a telescopic fashion. In five subjects coils were used in addition to the SILK stent. The mean duration of followup was 15.3 months (s.d. 7.9). Reduction of flow within the aneurysm was achieved and visualized in all 15 patients (100%) at the immediate post-treatment angiography. Complete occlusion of the aneurysm was observed in 12 cases at their latest neuroradiologic study (12/15; 80%). In the remaining three patients (20%) a residual flow in the aneurysm still was observed at their latest follow-up exam (one at eight-month followup, two at 24-month followup).

Conclusion

In our three years experience of SILK stent use, a total of 15 patients and 16 aneurysms were treated at our Institution. Our data showed good results in terms of complete occlusion of the aneurysms, which was achieved and maintained in 80% of cases as of their latest follow-up study.

Single Center Direct Comparison of Neuroform and Enterprise Stents in the Treatment of Wide-Necked Intracranial Aneurysms

Durst, C.[1]·Khan, P.[2]·Gaughen, J.[1]·Patrie, J.[1]·Jensen, M.[1]·Evans, A.[1]
[1]University of Virginia, Charlottesville, VA, [2]Batra Hospital and Medical Reseach Centre, New Dehli, INDIA.

Purpose

Individually, the technical successes, clinical outcomes, and complications for Neuroform and Enterprise stents have been well documented. However, few studies have directly compared the technical or clinical outcomes of both stents. This study represents only the second report of a direct comparison of not only the technical and clinical outcomes, but also the complications associated with the use of each stent at a single institution.

Materials & Methods

A retrospective chart review identified 109 patients who underwent stent-assisted coil embolization for the treatment of a wide-neck aneurysm, which was defined as an aneurysm with either a dome to neck ratio of less than two or a neck diameter greater than 4 mm. Immediate and long-term clinical and imaging outcomes were recorded for all patients.

Results

Our technical success rate of 95.8% is concordant with that reported in the literature. Primary occlusion rates were 15.6% while an additional 32.8% of the treated aneurysms showed delayed occlusion on follow-up imaging and an additional 12.5% demonstrated progressive but incomplete occlusion on later exams. There were 18.8% of the treated aneurysms recanalized with an equal distribution between the Neuroform and Enterprise stents. However, major complication rates were three-fold higher with Enterprise stents as compared to Neuroform stents, 15.4% versus 4.5%, respectively. In total, eight out of the 10 major complications experienced with Enterprise stents occurred in vessels deemed tortuous. Conversely, only one major complication occurred in tortuous vessels using the Neuroform stent.

Conclusion

Although this study is retrospective and nonrandomized, it represents one of the first direct comparisons of Enterprise and Neuroform stents, limiting intra-operator variability. Our technical and clinical outcomes were individually similar to those of other institutions. There is no significant difference in the immediate or long-term occlusion or recurrence rates between the Enterprise and Neuroform stents. However, our data suggest an increased risk of major complication, particularly infarction, when using an Enterprise stent.

Endovascular Treatment of Intracranial Aneurysms: Occurrence of Thromboembolic Events

Lee, Y.·Yoo, W.
Catholic University of Korea
Bucheon, Wonmigu, Sosadong, KOREA, REPUBLIC OF.

Purpose
To evaluate the frequency and causes of thromboembolic events associated with endovascular embolization of intracranial aneurysms. Correlations between radiologic findings (aneurysm size, localization, embolization time, number of coils used, as well as patient age) were evaluated with the occurrence of thromboembolic events.
Materials & Methods
Three hundred sixty-eight patients treated with coil embolization (396 total procedures) between March 2007 and September 2012 were included. All patients underwent a routine diffusion-weighted magnetic resonance imaging (DWI) within the 72 hours after the intervention for the detection of ischemic complications.
Results
Thromboembolic complications were more common in patients with ruptured aneurysms (12/23, 51%) than in those with unruptured aneurysms (112/373, 30%).The incidence of DWI abnormalities was higher in older patients (≥60 years) when compared to younger patients (≤60 years). There was no correlation between aneurysm location and the occurrence of lesions or among the number of coils used, the size of the aneurysm, or embolization time.
Conclusion
In order to provide adequate and timely treatment, a routine DWI followup after coil embolization of intracranial aneurysms might be helpful, especially in older patients.

Curative Embolization of Brain Arteriovenous Malformations with Onyx: Patient Selection, Embolization Technique, and Outcome

Mansour, O.
Alexandria University
Alexandria, EGYPT.

Purpose
A new curative embolization technique with Onyx for selected small and medium-sized superficially located brain AVMs was developed, which consists of obliteration of the nidus, including incremental occlusion of the draining veins. We report our first clinical results.
Materials & Methods
Between June 2008 and July 2011, 24 patients (seven women, 17 men; mean age, 41 years; range, 6-74 years) with AVMs were selected for curative embolization with Onyx. Presentation was hemorrhage in 14 and seizures in 10 patients. AVM location was frontal in 11, occipital in six, parietal in four, and temporal in three. Arteriovenous malformation size was a mean of 2.2 cm (median, 2; range, 1-3 cm).
Results
Complete angiographic obliteration of the AVM with Onyx in a single session was achieved in all 24 patients. There were no hemorrhagic or ischemic complications (0%; 95% CI, 0%-16.3%), and no new deficits induced by the treatment. Of 14 patients with ruptured AVMs, one patient who presented with a large frontal hematoma died shortly after surgical evacuation of the hematoma following complete embolization of a micro-AVM. Follow-up angiography at three months in 23 patients demonstrated a small AVM remnant in one that was treated with gamma knife radiosurgery. The other 22 AVMs remained completely occluded.
Conclusion
In selected patients with small and medium-sized superficial brain AVMs, as defined in our study, injection of Onyx by using a curative embolization technique in a single session seems to provide a safe and effective alternative to radiosurgery or surgery.

Color Doppler-Guided Percutaneous Sclerotherapy of Smaller Facial Arteriovenous Malformation

Bhalla, N.[1]·Bhalla, M.[2]
[1]Victoria Jubilee Hospital, Ahmedabad, INDIA, [2]Medical College of Wisconsin, Milwaukee, WI.

Purpose
To evaluate efficacy of percutaneous treatment of facial arteriovenous malformation (AVM) measuring less than 4 cm, using polidocanaol 3% under color doppler (CD) guidance in outpatient clinical settings.
Materials & Methods
Six patients with facial AVM identified and measured on CD examination as less than 4 cm were treated with CD-guided percutaneous foam sclerotherapy during July 2008 and February 2010 on clinic basis. Following informed consent, lesion site was prepped in routine fashion, and venous side of lesion was identified on CD and compressed manually. The lesions were percutaneously punctured under CD guidance using 21 gauge needle. Polidocanol 3% diluted 50% with distilled water was foamed using Tessari's technique and was injected into the lesion. Polidocanol (1-3 cc) was used depending on lesion size. Treated site was kept compressed for 20 minutes following the procedure. Up to three such sessions were performed. Results were considered as worsened, totally occluded, partially occluded and unsuccessful based on CD

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

findings and clinical examination. None of the patients were admitted indoor or required hospital stay.
Results
Complete occlusion of AVM was achieved in four patients in up to three sittings, three of which showed reduced lesion size. Two of the six patients achieved partial occlusion with reduced vascularity. None of them worsened and none of the procedure-related complication was noted. All patients complained of transient swelling, tenderness and discoloration at local site for up to one week.
Conclusion
Percuatenous sclerotherpy of facial AVM measuring less than 4 cm on CD study, is a safe and effective procedure which is reasonably effective with very low morbidity or complication and gives good clinical improvement, even when performed on outpatient clinic basis.

eP-155

A Multidisciplinary Team Approach to Treating Intracranial Arteriovenous Malformations in a Regional Neuroscience Center

Davis, E.·O'Leary, S.·Flynn, P.·Smyth, G.·McKinstry, S.·Abouharb, A.·Simms, H. N.·Rennie, I.
Royal Victoria Hospital
Belfast, UNITED KINGDOM.

Purpose
To evaluate the management and treatment of intracranial AVMs and their outcomes over a five-year period in a regional center. Intracranial arteriovenous malformations (AVMs) are a relatively uncommon entity but can prove fatal or result in serious neurologic sequelae. With advances in radiologic imaging techniques these lesions are increasingly recognized and there are myriad approaches to treatment with no defined gold standard and treatment protocols based on locally available expertise. The decision regarding treatment is complex and involves a number of factors including whether the lesion is ruptured or unruptured, how amenable it is to treatment based largely on the Spetzler-Martin grading system, patient wishes as well as compromise between risk versus benefit. In our institution we have adopted a multidisciplinary team approach with all treatment options considered.
Materials & Methods
Retrospective chart review of all patients with AVMs managed by our unit over the past five years. Patients charts were assessed and the following information extrapolated: (1) Spetzler-Martin grade of all patients. (2) Multidisciplinary team meeting notes were evaluated to see which treatment options were offered and (3) Whether a stereotactic radiosurgical opinion was sought. (4) What discussions were had with the patient. (5) What treatment plan was ultimately decided upon. (6) What the outcome of the treatment was. (7) Whether more than one treatment was employed and how many times and lastly (8) Morbidity and mortality.
Results
In our institution we have adopted a multidisciplinary team approach involving both neurosurgery and neuroradiology. This includes endovascular embolization with glue and onyx and surgical resection, with these options available locally. As well as this the majority of unruptured AVMs are referred for a Stereotactic Radio-Surgical opinion. This adjunct to our locally available expertise is invaluable and ensures that we are capable of offering a comprehensive service for the treatment of AVMs. All treatment options are carefully considered and often patients ultimately have a combination of treatment modalities with a common pathway being for embolization prior to completion stereotactic radiosurgery. In our institution over the past five years, we have treated over 100 patients - 33.6% of these were treated with embolization only, 32.7% had stereotactic radiosurgery only with a further 24% going on to have a combination of both embolization and stereotactic radiosurgery and 4.8% were managed conservatively. Of the remaining patients, two patients did not attend followup, one resolved spontaneously, one additional patient was deemed untreatable following review by the multidisciplinary team and another patient died from unrelated causes prior to treatment. Processes, complication rates, etc. to be included at a later date.
Conclusion
With the various treatment options available and lack of level I or II evidence available in the literature regarding treatment, we feel that a multidisciplinary team approach, as offered in our institution, is the optimum approach and most beneficial to the patient. This combined approach leads to thorough evaluation and input from all specialties involved in AVM treatment.

KEYWORDS: Arteriovenous malformation, multidisciplinary

eP-156

Novel Technique for Selective Ophthalmic Artery Infusion Chemotherapy of Retinoblastoma in Children with Retrograde Ophthalmic Artery Flow

Abruzzo, T. A.[1]·Kimbrough, D. A.[2]·Cornell, K.[1]·Augsburger, J.[1]·Geller, J.[1]
[1]Cincinnati Childrens Hospital Medical Center, Cincinnati, OH, [2]University of Cincinnati Medial Center, Cincinnati, OH.

Purpose
Selective ophthalmic artery (OA) infusion chemotherapy (SOAIC) is an alternative to enucleation for the treatment of advanced intra-ocular retinoblastoma. In many children, microcatheter placement in the OA causes flow reversal and precludes delivery of chemotherapeutic agents to the

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

tumor. The purpose of this work was to develop an interventional technique for stable conversion of retrograde OA flow to anterograde during SOAIC.
Materials & Methods
Between June 2009 and December 2012, patients with unilateral or bilateral International Classification System group C and D retinoblastoma and intact visual function were treated by SOAIC using melphalan, topotecan, or combinations of melphalan, topotecan and carboplatin depending on prior systemic chemotherapy regimens. Treatment cycles were every three to four weeks until examination under anesthesia (EUA) revealed stable tumor remission. Adjunctive therapies including subconjunctival carboplatin injections and cryotherapy were administered depending on the initial response to treatment and the extent of vitreal seeding. All SOAIC treatments were administered by placing a 4 French introducer sheath in the femoral artery and a coaxial 4 French diagnostic catheter in the internal carotid artery on the side of the tumor. Systemic heparin anticoagulation was administered in addition to adjunctive nebulized albuterol, intravenous decadron and intranasal Afrin. Chemoinfusions were administered through coaxial 1.2-1.5 French microcatheters placed through the diagnostic catheter and into the OA ostium. Ophthalmic artery hemodynamics were assessed by microcatheter angiography. If OA flow was anterograde the age-adjusted dose of chemotherapy was administered through the microcatheter in a total volume of 30-45 ml over a period of 30-40 minutes. If retrograde OA flow was demonstrated, temporary balloon occlusion (TBO) of the ipsilateral external carotid artery (ECA) was performed using an over-the-wire balloon occlusion catheter. Anterograde OA flow was confirmed by microcatheter angiography before and after intra-arterial administration of chemotherapy.
Results
Thirteen eyes with retinoblastoma were treated in 12 patients (four male). Patients ranged in age from seven to 96 months. Each eye was administered 2-10 treatment cycles, (average five). Sixty-two procedures were performed. In six patients, OA flow became retrograde after microcatheter placement. In all six patients TBO of the ECA restored anterograde flow to the OA. Anterograde OA flow remained stable throughout each SOAIC procedure enabling effective delivery of the entire chemotherapy dose to the intraocular tumor target. Twenty-two SOAIC procedures were performed with TBO of the ECA. There was no serious morbidity or complications directly attributable to the balloon occlusion procedure. Two of the seven eyes treated by standard SOAIC technique were enucleated because of suspicious findings on EUA, both of which were histologically negative for tumor. One of the six eyes treated with adjunctive TBO of the ECA was enucleated because of treatment refractory vitreal seeds. Two patients managed with standard SOAIC technique still are actively being treated. One patient currently is being managed with the TBO technique. All remaining patients have been in tumor-free remission an average of five months.
Conclusion
Temporary balloon occlusion of the ECA is a safe and effective means of managing retrograde OA flow in children undergoing SOAIC.

Carotid Blowout Syndrome: Endovascular Management by Stenting and Embolization

Tisnado, J.[1]·Fox, W. C.[1]·Amendola, M. A.[2]·Sydnor, M. K.[1]·Amendola, C.[3]·Ehlenberger, C. A.[1]·Tisnado, J.[4]
[1]Medical College of Virginia Hospitals/VCU Medical Center, Richmond, VA, [2]Innovative Cancer Institute, South Miami, FL, [3]Georgetown University, Washington, DC, [4]Hartford General Hospital, Hartford, CT.

Purpose
Carotid blow out syndrome (CBOS) is a catastrophic emergency associated with high morbidity and mortality (M&M). The usual causes are: head and neck malignant tumor invasion, postoperative, postradiation therapy, inflammatory and trauma, among others. The conventional surgical management, including carotid artery and/or branch ligation and/or carotid artery bypass, is fraught with high M&M, may be ineffective and result with limited success. With the advent of covered and uncovered, balloon-expandable or self-expandable metallic stents, the emergent management of CBOS has improved and currently a permanent or temporary success in the endovascular management is expected.
Materials & Methods
During the last few years, we have studied 15 patients (adults and children, male and female) with CBOS of different etiologies, considered difficult or not manageable by surgery. The insertion of different types of stents, covered or uncovered, self-expanding or balloon-expandable, has been successful. We have used Gore Viabahn® Endoprosthesis, iCast™ (Atrium), Fluency® Plus Stent-Graft (Bard), Wallstent and Wallgraft (Boston Scientific) and Protégé (Bard). All procedures have been done in the IR suite and were successful in temporarily managing CBOS. No major stenting or embolization complications occurred. The patients had a relatively long or a temporary survival in a short followup.
Results
The emergency insertion of stents is a safe, effective and relatively easy procedure to permanently or temporarily manage CBOS. A longer followup and more patients treated are necessary to determine the long-term role of stenting in CBOS.
Conclusion
The surgical management is difficult and may be ineffective. The placement of stents, with or without

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

adjuvant embolization, must be considered the first choice to manage CBOS, particularly in desperate situations.

KEYWORDS: Carotid artery stenting, Mortality, head and neck tumor

Impact of Pretreatment Diffusion-Weighted Imaging ASPECTS on the Outcomes of Mechanical Thrombectomy for Acute Anterior Circulation Stroke

Yoon, W.·Jung, M.·Jung, S.·Kang, H.
Chonnam National University Hospital
Gwangju, KOREA, REPUBLIC OF.

Purpose
Correlation between pretreatment lesion size on diffusion-weighted imaging (DWI) and functional outcome in acute ischemic stroke is still unclear. The aim of this study was to assess whether the Alberta Stroke Program Early CT Score (ASPECTS) on DWI can reliably predict clinical outcomes at three months following mechanical thrombectomy therapy in patients with acute anterior circulation stroke.
Materials & Methods
Fifty-four consecutive patients with anterior circulation stroke treated with mechanical thrombectomy using Solitaire stent system within six hours after symptom onset were enrolled. ASPECTS was assessed on DWI just prior to the mechanical thrombectomy. Diffusion-weighted imaging ASPECTS scores were either categorized into 0 to 6 (n = 27) or 7 to 10 (n = 27). The primary outcome measure was a modified Rankin Scale (mRS) score of 0-2 at three months.
Results
The median ASPECTS on DWI was 6.5. At three months, 21 (39%) had an mRS score of 0-2, and three patients (5.5%) had died. Patients with an mRS score of 0-2 (good outcome) were younger (61 ± 15.4) than other patients (73 ± 8.6, $p = 0.003$), had lower rates of previous coronary artery disease (0% vs 18.1%, $p = 0.038$), and had higher rate of recanalization (100% vs 51.5%, $p<0.001$). Of patients with DWI ASPECTS 7-10, 48.1% had good outcome. Of those with DWI ASPECTS 0-6, 29.6% had good outcome. There was no significant association between DWI ASPECTS and clinical outcome ($p = 0.163$). On multivariate regression analysis, independent predictor of good outcome (mRS 0-2) was patient's age (odds ratio = 0.922, $p = 0.02$).
Conclusion
Diffusion-weighted imaging ASPECTS does not seem to impact on clinical outcomes after mechanical thrombectomy in patients with acute anterior circulation stroke. Patient's age, history of coronary artery disease, and recanalization status were significantly associated with clinical outcomes after mechanical thrombectomy for acute anterior circulation stroke.

Emergent Carotid Artery Stenting within Six Hours after Onset of Acute Ischemic Stroke

Yoon, W.·Jung, M.·Jung, S.·Kang, H.
Chonnam National University Hospital
Gwangju, KOREA, REPUBLIC OF.

Purpose
Acute ischemic stroke attributable to atherosclerotic steno-occlusive disease of extracranial internal carotid artery (ICA) carries a poor prognosis. The purpose of this study was to investigate the recanalization rate and clinical outcomes following emergent carotid artery stenting for hyperacute ischemic stroke.
Materials & Methods
Carotid artery stenting was performed in 28 patients with acute atherosclerotic steno-occlusive disease of extracranial ICA within six hours of stroke onset. Of these patients, 23 patients had tandem intracranial arterial occlusion at the level of ICA terminus (n = 2), M1 segment of middle cerebral artery (MCA) (n = 14), M2 segment of MCA (n = 4), and M3 segment of MCA (n = 3). Treatment for intracranial occlusions included mechanical thrombectomy, or combination of mechanical clot disruption and intra-arterial urokinase infusion. Successful recanalization was defined as successful extracranial ICA stent placement plus intracranial thrombolysis in cerebral ischemia (TICI) grade 2b or 3 after the treatment. The primary outcome measure was a modified Rankin Scale (mRS) score of 0-2 at three months.
Results
Median patient age was 71 years, and median NIHSS score at presentation was 11. Overall, successful recanalization rate was in 57.1% (16/28). Symptomatic intracerebral hemorrhage occurred in one patient (3.6%). Sixteen patients (57.1%) had a good clinical outcome (mRS 0-2) at three months. Successfully recanalized patients had a significantly higher rate of good outcome than those without recanalization at three months (75% vs 33%, $P = 0.027$). Patients without intracranial tandem occlusion had a more favorable clinical outcome than those with intracranial occlusion (100% vs 47.8%, $P = 0.033$). Mortality was 0% (0/28) at three months.
Conclusion
Emergent carotid artery stenting in acute atherosclerotic extracranial ICA steno-occlusive disease has a relatively high recanalization rate with a good clinical outcome in more than half of the patients. Successful recanalization (extracranial and intracranial) is associated with a good outcome in our cohort of patients undergoing emergent carotid artery stenting.

KEYWORDS: Actue stroke, Carotid artery stenting, emergencies

Outcome of Mechanical Thrombectomy with the Solitaire Stent in Acute Intracranial Internal Carotid Artery Occlusion

Yoon, W.·Jung, M.·Jung, S.·Kang, H.
Chonnam National University Hospital
Gwangju, KOREA, REPUBLIC OF.

Purpose
Acute stroke from occlusion of the intracranial internal carotid artery (ICA) is associated with a poor clinical outcome despite intravenous or intra-arterial thrombolytic treatment. Mechanical thrombectomy using retrievable stents is a newly available modality for acute stroke therapy. The purpose of this study was to evaluate the safety and efficacy of mechanical thrombectomy using Solitaire stent in the treatment of patients with acute intracranial ICA occlusion.
Materials & Methods
Between November 2010 and March 2012, a total of 64 consecutive patients with acute ischemic stroke were treated with mechanical thrombectomy by using Solitaire stent at our center. Of those patients, we retrospectively reviewed 17 consecutive patients presented with acute stroke attributable to ICA terminus occlusion within six hours from symptom onset. Successful recanalization was defined as thrombolysis in cerebral ischemia (TICI) grade 2b or 3. The primary outcome measure was a modified Rankin Scale (mRS) score of 0-2 at three months.
Results
Median patient age was 70 years, and median NIHSS score at presentation was 14. Median procedure time was 54 minutes. Overall, successful recanalization was achieved in 64.7% (11/17). No symptomatic intracerebral hemorrhage occurred. Five patients (29.4%) had a good clinical outcome (mRS 0-2) at three months. Good outcome occurred in 46% of patients (5/11) with recanalization and in 0% of patients without recanalization (P = 0.049). Mortality was 5.9% (1/17) at three months.
Conclusion
Mechanical thrombectomy using Solitaire stent has a relatively high recanalization rate with a good outcome in one third of patients and a significantly low mortality rate in patients with acute ICA occlusion. Patients with successful recanalization by Solitaire thrombectomy have improved clinical outcome compared with those patients without recanalization.

Absorbed Dose Measurements of Flat Panel CT Acquisitions for Parenchymal Blood Volume Estimates in Interventional Radiology

Supanich, M. P.[1]·Theesen, H.[2]·Sanders, W.[1]
[1]Henry Ford Health System, Detroit, MI, [2]Siemens AG, Hoffman Estates, IL.

Purpose
The use of flat panel CT in interventional neuroradiology settings has increased in recent years due to the ability to acquire and display of CT-like images, CT angiograms (CTAs) and blood volume maps. The use of these image sets during a treatment holds particular promise in stroke management. To date, there has been no characterization of the absorbed dose to the brain from flat panel CT studies. Given the increased focus on radiation dose in the community and the fact that many patients undergoing an interventional procedure are subjected to multiple studies using ionizing radiation, assessing the radiation dose of these studies is important.
Materials & Methods
Absorbed radiation dose measurements were performed using a 0.6 cc ionization chamber and digital electrometer from Radcal Corporation. A modified anthropomorphic head phantom from Phantom Laboratory composed of tissue equivalent material and a human skull was utilized to obtain the absorbed dose measurements. Holes were drilled in the phantom to allow insertion of the ion chamber for measurements. Tissue equivalent rods were placed in the holes not used for the dose measurement. Absorbed dose measurements of a standard parenchymal blood volume technique using two consecutive spins were made on a Siemens Artis Zee biplane system. Each spin was acquired over eight seconds with the dose to the detector set at 0.36 uGy per view. The ionization chamber was placed in the center hole of the head phantom and located at the level of the eyes. Average tube potential and tube current reported for each spin were 72 kV and 528 mA, respectively. The system reported the Air KERMA for each spin was 114 mGy. Measurements of absorbed dose in both standard noncontrast CT, CTA and shuttle CT perfusion (CTP) of the head were performed on GE CT systems. The ionization chamber placement replicated that of the flat panel CT acquisition. The scan ranges were consistent with clinical practice. The acquisitions were performed using automatic exposure control and the scanner reported $CTDI_{vol}$ was 63.6 mGy(head-16cm), 29.4 mGy(head-16cm) and 120.5 mGy(head-16cm) for the CT, CTA and CTP studies, respectively.
Results
The measured absorbed dose in the center of the phantom's brain was recorded from the digital electrometer used to read out the ionization chamber. The total absorbed dose from the two spins of the flat panel CT acquisition was 29.1 mGy. The measured absorbed doses were 48.0 mGy, 21.4 mGy and 78.4 mGy for the CT, CTA

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

and CTP studies, respectively.
Conclusion
The acquisition of flat panel CT data using a dual spin acquisition following the intravenous injection of contrast agent in an interventional setting provides whole brain noncontrast CT images, parenchymal blood volume maps and 3D images with enhancement of both arteries and veins. These three datasets can be acquired at an absorbed dose nearly equivalent to a standard head CTA, at 60% of the dose of a standard head CT, and at more than half the dose of our institution's CTP protocol.

Dose Reduction in 3D Rotational Angiography with Axial Collimation

Radvany, M. G.[1]·Banckwitz, R.[2]·Koehler, C.[2]·Ehtiati, T.[3]·Mahesh, M.[1]
[1]Johns Hopkins University School of Medicine, Baltimore, MD, [2]Siemens, Forcheim, GERMANY, [3]Siemens, Princeton, NJ.

Purpose
As 3D tomographic imaging in flat panel systems is used more frequently it is important to consider methods for limiting the total radiation dose during the procedure. Different operators perform 3D acquisitions using varying modes to acquire data including different degrees of magnification and axial collimation. In this paper we present a study to demonstrate that axial collimation significantly reduces the effective radiation dose to the patient without reducing the diagnostic quality of the image data.
Materials & Methods
Dose measurements were performed using Rando Alderson 73 kg anthropomorphic phantom. This phantom is equipped with slices of 2.5 cm thickness for carrying thermoluminescent dose meter (TLD). Thermoluminescent doses were inserted in different measurement locations inside the Alderson phantom. The phantom was examined under the C-arm angiographic system AXIOM Artis (Siemens Healthcare, Germany) with a 30 x 40 cm flat image detector, using 5s 3D DSA protocols (syngo 3D DSA, Siemens Healthcare, Germany) at 48 cm FOV and 42 cm FOV without axial collimation, and then repeated using axial collimation of approximately 30%. The dose area product (DAP) also was recorded for each acquisition. The radiation dose measurement in Sievert, averaged over the TLDs, then is converted to effective dose. Subsequently we searched the radiology database for patients who underwent cerebral angiography with 3D rotational angiography to find and compare image quality at different rates of magnification and collimation. When the angiography suite was installed, operators routinely obtained rotational angiograms without collimation at 48 cm and 42 cm FOV while gaining familiarity with the equipment. Subsequent software updates allowed collimation in the axial direction and a 30% collimation was adopted for all studies unless clinically indicated.
Results
The results of the measurements performed on Alderson phantom show that the 5s 3D DSA protocol without any axial collimation has an effective dose of 0.9 mSv for both zoom rates, while the same protocol with an axial collimation of about 30% of FOV has an effective dose of 0.7 mSv for both zoom rates. The DAP for the same acquisitions was 155.2 $mGym^2$ for 48 cm FOV, and 119.8 $mGym^2$ for 42 cm FOV. Using axial collimation the DAP was reduced to 73.9 $mGym^2$ and 50.6 $mGym^2$ at 48 and 42 cm FOV respectively. In clinical studies we found that the image quality was maintained using axial collimation. The mean DAP on 48cm FOV was 695.9 $mGym^2$ and 1230 $mGym^2$, with and without collimation respectively. The DAP on studies obtained at 42cm FOV was 392.3 $mGym^2$ and 1008.9 $mGym^2$, with and without collimation respectively.
Conclusion
Axial collimation can be used to reduce the effective dose by approximately 25% without sacrificing diagnostic image quality. The phantom experiment shows that the effective dose is not reduced by change in magnification rate, therefore changing FOV from 48 cm to 42 cm is not a reliable technique for reducing radiation dose and should be practiced carefully to avoid truncation artifacts.

Clinical Outcomes of Coiling Ruptured Aneurysms Have Significantly Improved: A Meta-Analysis of Outcome of Coiling in Hydrocoil Endovascular Occlusion and Packing Study and the Cerecyte Coil Trial Compared with the International Subarachnoid Aneurysm Trial

Molyneux, A. J.[1]·Graham, C.[2]·Williams, C.[3]·Sneade, M.[1]·Forrester, L.[2]·White, P.[4]
[1]Oxford University, Oxford, UNITED KINGDOM, [2]Edinburgh University, Edinburgh, UNITED KINGDOM, [3]Glasgow University, Glasgow, UNITED KINGDOM, [4]Newcastle University, Newcastle, UNITED KINGDOM.

Purpose
To determine clinical outcomes at discharge and three - six months in patients with subarachnoid hemorrhage from a ruptured aneurysm prospectively enrolled in the Hydrocoil Endovascular occlusion and Packing Study (HELPS) and the Cerecyte Coil Trial (CCT) and to compare with the one-year outcomes in similar patients in the International Subarachnoid Aneurysm Trial (ISAT).
Materials & Methods
A predefined protocol of the meta-analysis has been presented previously. The study included all patients enrolled in HELPS2 and CCT3 who were WFNS grade 1 and 2 at the time of randomization. These were compared with

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

the comparable ISAT patients allocated to clipping and coiling and were good grade at the time of randomization and in good grade at the time of treatment; patients who died, rebled, deteriorated due to delayed ischemic deficit or who crossed over to the other treatment were excluded. We prespecified the same subgroups as in ISAT. We examined procedural complications, discharge outcomes, rebleeding rates and three and six months clinical outcomes in HELPS and CCT respectively and compared these with 12 months outcomes in ISAT. Of 999 patients enrolled in the HELPS and CCT randomized trials, 487 patients were enrolled and treated for a recently ruptured aneurysm were in good clinical grade, WFNS 1 & 2. In the ISAT cohort 832 of 1073 patients allocated to coiling, and 846 of 1070 allocated to clipping fulfilled the eligibility criteria.

Results

There were more large aneurysms and posterior circulation aneurysms in HELPS/CCT than ISAT- 15·3% versus 6·1% large (p<0·001) and 11·4% versus 2·4% posterior circulation respectively (p<0·001). Otherwise the baseline characteristics were similar. Procedural rupture was reported in 171/846 (20·2%) of the ISAT clipping group, 46/832 (5·5%) of the ISAT coiling group and 24/487 (4·9%) of the HELPS/CCT group (p = 0.7). Thrombo-embolic complication was reported in 22/846 (2·6%) of the ISAT clipping group, 38/832 (4·5%) of the ISAT coiling group and 11/487(2·2%) of the HELPS/CCT group, p = 0.86 (versus ISAT clipping) and p = 0.035 (versus ISAT coiling) respectively. Rebleeding after treatment occurred in 4/487 (0·8%), in HELPS/CCT, compared with a total of 23/832 in the ISAT coiling group (2·8%), (p = 0.015) and a rebleed rate of 10/846 (1·2%), (p = 0.78) in the ISAT clipping group. Discharge home was seen in 35·5% of the ISAT clipping group, 46·5% of the ISAT coiling and 69·2% of the HELPS/CCT group. (p = <0.001). Independent outcome (mRS 0-2) was observed at followup, (3/6 months HELPS/CCT, one year ISAT) in 630/846 (72.7%), 682/832 (81.8%) and 418/487 (88.2%) in ISAT clipping, ISAT coiling and HELPS/CCT respectively. The case fatality at one year was 6·2%, 4·9% and 3·4%, in ISAT clipping, ISAT coiling and HELPS/CCT respectively.

Conclusion

The recent clinical outcomes of coiling have significant improved compared with the period of ISAT enrollment from 1994 to 2002. These findings further reinforce the significant clinical benefit of coiling compared with clipping for suitable aneurysms.

Comparison of 3D Rotational Angiography with Its Axial Source Images in the Evaluation of Intracranial Aneurysm Dimensions

Ferris, M.[1]·Stokum, C.[1]·Ashruf, S.[1]·Abu-Zahra, K. W.[1,2]
[1]University of Maryland, Baltimore, MD, [2]Mecklenburg Radiology Associates/Novant Healthcare, Charlotte, NC.

Purpose

3D rotational angiography (3DRA) is a staple in the evaluation of intracranial aneurysms for endovascular treatment. 3D rotational angiography is superior to 2D digital subtraction angiography (2D DSA) in determining an aneurysm's spatial relationships, but is inferior in its ability to accurately measure aneurysm dimensions due to postprocessing in the construction of 3DRA from axial source images (ASI). The purpose of this study is to further describe the measurement accuracy of 3DRA using ASI as a standard of reference.

Materials & Methods

A retrospective analysis of 49 patients with 52 intracranial aneurysms who underwent 3DRA for evaluation of previously untreated aneurysms was conducted. Two neuroradiologists measured the dimensions of each aneurysm using 3DRA and corresponding ASI. The mean difference in neck sizes and dome-to-neck ratios between 3D RA and ASI were calculated. The proportions of "wide-neck" aneurysms seen on 3DRA and ASI were compared using two different definitions of "wide-neck," including <1.5 and <2.0. Interobserver variability was calculated in all instances.

Results

For Observer A: the average difference in neck size was 0.78 mm. ± 0.90 (P < .0001); the average difference in dome-to-neck ratio was 0.32 ± 0.77 (P < .0001). For Observer B: the average difference in neck size was 0.87 mm. ± 0.61 (P < .0001); the average difference in dome-to-neck ratio was 0.23 ± 0.48 (P < .0001). The two readers demonstrated no significant difference (all P < .0001) and good correlation in their measurements of: neck size in 3DRA (r = 0.8428), neck size in ASI (r = 0.8764), and dome-to-neck ratio in 3DRA (r = 0.8085). The two readers demonstrated no significant difference (P = 0.0046) but weak correlation in their measurement of dome-to-neck ratio in ASI (r = 0.3869). With a definition of wide-neck as dome-to-neck ratio <1.5, no statistical difference was found between the two readers in their classification of aneurysms as wide-neck using either 3DRA (P = 1.0) or ASI (P = 0.6685); Observer A read 28 aneurysms(28/52; 53.8%) as wide-neck using 3DRA compared with 17 aneurysms (17/52; 32.7%) using ASI (P = 0.0477); Observer B read 27 aneurysms (27/52; 51.9%) as wide-neck using 3DRA compared with fourteen aneurysms (14/52; 26.9%) using ASI (P = 0.0156). With a definition of wide-neck as dome-to-neck ratio <2.0, there was no statistical difference between the two readers in their classification of aneurysms as wide-neck using either 3DRA (P = 1.0) or ASI

(P = 0.4224); Observer A read 41 (41/52; 78.8%) aneurysms as wide-neck using 3D compared with 29(29/52; 55.8%) using ASI (P = 0.0208); Observer B read 41 (41/52; 78.8%) aneurysms as wide-neck using 3DRA compared with 34(34/52; 65.4%) using ASI (P = 0.1891).
Conclusion
In this retrospective study, 3DRA measurements significantly overestimated aneurysm neck sizes and significantly underestimated dome-to-neck ratio, with good agreement between two readers. Aneurysm neck size and dome-to-neck ratio are essential determinants in the decision to treat endovascularly and in device selection. Axial source image analysis should supplement 3DRA in the evaluation of intracranial aneurysms for endovascular treatment.

Stent-Assisted Coil Embolization of Aneurysms with Small Parent Vessels (≤ 2 mm): Safety and Efficacy Analysis

Puri, A. S.·Kuhn, A.·Hou, S.·Gounis, M. J.·Wakhloo, A. K.
University of Massachusetts Medical Center
Worcester, MA.

Purpose
Stent-assisted coil embolization (SACE) is a new therapeutic approach for wide-neck intracranial aneurysms. Stent-assisted coil embolization however can be technically challenging in small cerebral vessels (≤2 mm). Only a limited number of case series are available in the literature that have studied the safety and efficacy profile. We present our experience with currently approved stents for SACE of aneurysms with small cerebral vessels.
Materials & Methods
We identified all patients who underwent SACE with either a Neuroform or an Enterprise stent at our institution between June 2006 and October 2012. Only patients with a parent artery diameter of ≤2 mm were included. Patient comorbidities (arterial hypertension, smoking, hyperlipidemia, and coronary artery disease) and aneurysm characteristics (ruptured versus nonruptured, incidental finding, recanalized) were documented and angiographic follow-up data were reviewed.
Results
A total of 41 patients with 44 aneurysms met our criteria and were included in the study. The mean age was 54.5 years. Mean parent artery diameter was 1.7 mm (range 1.2 mm to 2 mm). Aneurysms were detected as incidental findings in 34.1%. Most aneurysms were located in the anterior circulation (75%). Middle cerebral artery aneurysms were found in 29.6% and anterior communicating artery aneurysms in 34.1% of cases. Aneurysms associated with symptoms were seen in 31.8%. Fourteen aneurysms had been previously coiled but recanalized and thus were retreated with stent-assisted coil embolization. In 54.5% of cases (n = 24) a Neuroform stent was used. Stent placement was successful in 41 cases (93.2%). Periprocedural thromboembolic complications occurred in six interventions (13.6%) but all were treated successfully with IA lysis (abciximab). Aneurysm rupture with SACE and vessel straightening was seen in one case (2.3%) each. Near complete or complete aneurysm obliteration was seen in 37 aneurysms (84.1%). Six-month follow-up angiography was available for 28 patients (68.3%). Coil compaction was seen in three cases one of which also revealed an in-stent stenosis but not requiring a retreatment. One stent occlusion was seen at followup, but did not require any further intervention due to excellent collaterals. Longer-term followup at 12 to 20 months were available in 13 patients. In two cases coil compaction remained stable compared to the six-month followup and in two cases new aneurysm recanalization was noticed. No in-stent stenosis was found. Three-year follow-up angiography was available for four patients. Further coil compaction was seen in one patient who had previously shown stable recanalization at six and 12 month follow-up angiography. Retreatment was only necessary in this single case.
Conclusion
Our results suggest that SACE of aneurysms with parent vessels ≤2mm in diameter is feasible with acceptable periprocedural complications and excellent long-term patency rate of parent arteries. However, like with other locations, recanalization, although low, remains an issue.

P2Y12 Assay Values in the Prediction of Thromboembolic Events after Neurointervention

Gingras, J.·Clopton, D.·Durst, C.·Schweickert, P.·Patrie, J.·Jensen, M. E.·Evans, A.
University of Virginia
Charlottesville, VA.

Purpose
Dual antiplatelet therapy has been established as the standard of care for prevention of in-stent thrombosis after placement of an intracranial stent. However, the desire to prevent in-stent thrombosis counters the need for the aneurysm to thrombose after coil embolization. Additionally, platelet inhibition predisposes patients to a number of complications, while the dose and treatment duration are not standardized. Expense, patient compliance, and associated complications demand the need for appropriate use of antiplatelet therapy in this patient population. The purpose of this study is to determine the odds of a patient having an adverse event as compared to the inhibition of aneurysm thrombosis based on the P2Y12 assay and Aspirin Reaction Unit (ARU) values.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Materials & Methods
A retrospective analysis identified 110 patients who had undergone stent-assisted coil embolization of a wide-neck aneurysm. Patients were reviewed by members of the research team not involved in the initial treatment. Patients who were treated electively were initiated on standard dual anti-platelet therapy of aspirin 325 mg and clopidogrel 75 mg three to five days prior to the procedure. Six patients presenting acutely with subarachnoid hemorrhage received antiplatelet therapy of aspirin and/or clopidogrel just prior to or during the procedure, depending on when it was determined that a stent would be required. Enterprise and all generations of Neuroform stents were included in this study. The patients were continued on aspirin and clopidogrel after treatment. Platelet inhibition was assessed using aspirin response units (ARU), while the "VerifyNow" P2Y12 assay was used to determine patient response to clopidogrel. The degree of aneurysm thrombosis was sequentially assessed for thrombosis using follow-up cerebral angiograms, computed tomography angiography (CTA), or magnetic resonance angiography (MRA). All complications related to the procedure were recorded from careful chart review. The statistical analysis controlled for the stent manufacturer and the presence or absence of subarachnoid hemorrhage.
Results
Logistic regression statistical analysis was performed using univariate and multivariate adjusted odds ratios. Analysis demonstrated that aspirin and clopidogrel levels did not effect aneurysm thrombosis after stent placement. Additionally, it was shown that treatment with clopidogrel does not increase the likelihood of aneurysm recannulization. While aspirin response levels did not correlate with the likelihood of major complication, the odds of a major complication after stenting were inversely related to the P2Y12 assay value ($p = 0.039$).
Conclusion
This study demonstrates a statistically significant increase in major complications as the response to clopidogrel antiplatelet therapy decreases as determined by the P2Y12 assay values. However, ARU values did not correlate with major complications. Additionally, aspirin and clopidogrel demonstrated no effect on aneurysm thrombosis or recannulization. These findings suggest that the P2Y12 values should be monitored in patients after placement of an intracranial stent. A prospective study would be warranted to determine the optimum P2Y12 threshold values, which will prevent major complications without inhibiting aneurysm thrombosis.

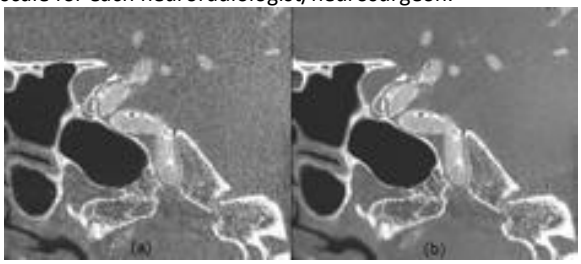
Noise Reduction Filter for Visualization of Enterprise VRD on High-Resolution CT-Like Imaging

Oishi, S.[1]·Yamada, M.[2]·Yokoyama, H.[2]·Shiraishi, K.[3]·Satow, T.[2]
[1]Toshiba Medical Systems Corp., Otawara, JAPAN, [2]National Cerebral and Cardiovascular Center Hospital, Suita, JAPAN, [3]Toshiba Medical Systems Engineering Co., Ltd., Otawara, JAPAN.

Purpose
Stent-assisted coiling is used as one of the treatment options for wide-neck aneurysms. Adaption of stent struts to vessel wall should be checked before starting coiling, but struts are almost invisible on x-ray acquisition data because of diameters of 60 μm in the case of Enterprise VRD. Stent imaging, high-resolution CT-like imaging, make those visible, but those are sometimes fragmented due to enhanced noise with high spatial resolution kernel. The fragmentation issues might cause difficulty in identifying kink of the struts. We have developed a dedicated noise reduction filter.
Materials & Methods
Existing noise reduction filter called coherence filter and the new noise reduction filter were applied to ten stent imaging data sets. The data were assessed independently by two experienced neuroradiologists/neurosurgeons, who were blinded to both images and patients, and a semiquantitative five-point grading scale (1 = poor, 5 = excellent) were used to score visibility of stent struts.
Results
The coherence filter and new noise reduction data were demonstrated on Figure 1(a) and Figure 1(b), respectively. Stent struts were clearly identified on Figure 1(b). Noise levels were decreased with the coherence filter and new noise reduction filter by 46.1% and 80.3% on average, respectively. Table 1 shows averaged five-point grading scale for each neuroradiologist/neurosurgeon.



Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Averaged five-point grading scale

	Coherence filter	New noise reduction filter
Neuroradiologist A	2.5	4.3
Neuroradiologist B	2.1	4.3

Conclusion
New noise reduction filter dramatically suppressed noise on high resolution CT-like imaging data without losing fine stent struts information. Kink of stent struts could be determined clearly with the new noise reduction data, and the well visualized struts will avoid unexpected complications at stent-assisted coiling.

Endovascular Management of Distal Posterior Inferior Cerebellar Aneurysms: Case Series

Boddu, S. R.·Noorian, A.·Schuette, A.·Tong, F. C.
Emory University Hospital
Atlanta, GA.

Purpose
Peripheral aneurysms of the posterior inferior cerebellar artery (PICA) are rare, and pre-existing literature concerning their endovascular treatment is limited. Posterior inferior cerebellar artery aneurysms are challenging, prone to procedural rupture and treatment strategies including surgical clipping and endovascular occlusion of the parent PICA are reported. In this study, we review endovascular management of five patients with distal PICA aneurysms, without sacrifice of the feeding artery.
Materials & Methods
Retrospective review of all the patients with treated peripheral PICA aneurysms at Emory University Hospital from May 2010 to May 2012 was performed. Clinical histories, radiologic images and operative reports were reviewed. Patients underwent emergent CT scan of the head if concerned for subarachnoid hemorrhage at presentation and 4-vessel diagnostic conventional angiography. CT scans were done postprocedure to insure the absence of PICA infarction. Patients were followed with conventional cerebral angiography.
Results
Five patients with a mean age at presentation: 60 years (range: 52-68 years). M:F-3:2. The clinical presentation was severe headache with nausea, vomiting and dizziness in all patients. None of them had seizures or focal motor neurologic deficits. Hunt and Hess scale at admission: Grade: 1 - one patient; Grade: 2 - one patient; Grade: 3 - two patients. Four of five (80%) patients had hydrocephalus; needed EVD and two of these patients had prolonged hospital stay from recurrent hydrocephalus and needed ventriculo-peritoneal shunt. Three of five patients had associated vascular malformations. Four patients had follow-up angiogram at three months and one patient at three and 12 months. One patient at three months followup had 30-40% recurrence and was treated with surgical clipping. Four of five patients had stable occlusion of the aneurysm at initial angiographic followup. No mortality or rebleeding was reported in the followup of patients as of this date.

Conclusion
We report a series of five distal PICA aneurysms with successful endovascular management and preservation of parent artery with no complication, good immediate and follow-up outcome. With rapid advances in endovascular techniques, the endovascular option can potentially be the first line to treat this critical condition with parent vessel preservation. Further large studies are warranted.

Cerebral Aneurysm Hemodynamic Alterations after Placement of a Flow-Diverter Stent

Takao, H.[1]·Suzuki, T.[1]·Tateshima, S.[2]·Masuda, S.[1]·Kadokura, S.[1]·Chein, A.[2]·Mohamed, A.[1]·Murayama, Y.[1]·Vinuela, F.[2]
[1]The Jikei University School of Medicine, Tokyo, JAPAN, [2]University of California Los Angeles, Los Angeles, CA.

Purpose
Currently, the placement of a stent as flow diverter (FD: Pipeline™) has been indicated as a treatment option, which has the potential to prevent aneurysm rupture by reducing hemodynamic forces and promoting aneurysm thrombosis. However, recent literature shows that some

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

seemingly successful treatments have been complicated by late hemorrhage. We believe that flow changes after placement of FD may cause some complications. We assessed this hypothesis through quantification of changes in intracranial aneurysm flow dynamics resulting from the placement of Pipeline stents.

Materials & Methods

Starting from DSA images before treatment, the aneurysm geometry was extracted and analyzed using a mathematical formula for fluid flow under pulsatile blood flow conditions. Commercial software (ANSYS ICEM CFD 13) was used for both mesh generation and fluid simulation. Simulations were performed before and after virtual placement of the Pipeline flow diverter, and hemodynamic parameters were compared in some parameters.

Results

Our result shows reductions in aneurysm velocity and wall shear stress (WSS), and increased pressure within the aneurysm after placement of this stent. This pressure increase is related to effective resistance in the parent artery due to placement of the device. The blood velocity into aneurysms decreased. In the parent artery, our result indicated increase of pressure, velocity and WSS.

Conclusion

Flow diverter devices can cause intra-aneurysmal and parent artery pressure increase. These hemodynamic changes in the parent artery and aneurysm may lead to rupture or treatment complications. Patient-specific CFD models potentially may be a useful tool in estimating the risks of device use before treatment using the FD stent.

Comparison of Contrast-Enhanced Time-Resolved MR Angiography and Digital Subtraction Angiography for Monitoring of Pipeline Embolization of Intracranial Aneurysms

Boddu, S.·Saindane, A. M.·Dehkharghani, S.·Tong, F.·Dion, J.
Emory University School of Medicine
Atlanta, GA.

Purpose

Endoluminal reconstruction and flow diversion using the pipeline embolization device is a novel treatment for cerebral aneurysms. Followup with digital subtraction angiography (DSA) has been reported following pipeline embolization; however, a noninvasive technique for monitoring extent of residual aneurysm filling, aneurysm recurrence, and in-stent stenosis is desirable. We hypothesize that contrast-enhanced time-resolved MRA (CE-TR-MRA) will provide a reliable and effective noninvasive method for following pipeline embolized aneurysms.

Materials & Methods

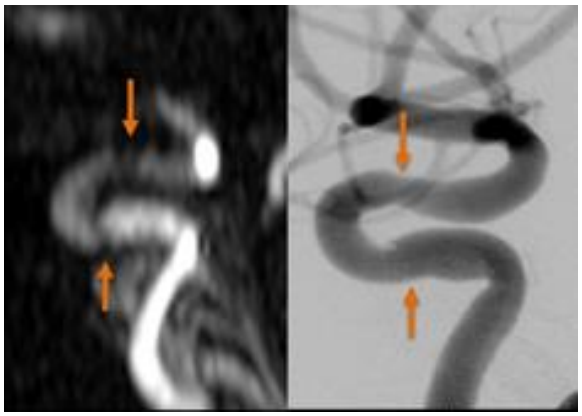
Over an 18-month period, patients with pipeline embolization of intracranial aneurysms who completed an initial follow-up evaluation with 3D time-of-flight (TOF) MRA, CE-TR-MRA, and DSA were reviewed. Twenty-nine pipeline embolized intracranial aneurysms in 21 patients were evaluated. Subjects underwent MRA on a 1.5T GE unit using both 3D-TOF-MRA and CE-TR-MRA using time-resolved imaging of contrast kinetics (TRICKS) with intravenous administration of a standard dose gadolinium-based contrast agent. Ten dynamic phases with submillimeter in-plane resolution and four-second temporal resolution were obtained. All patients underwent DSA within a median of 11.5 days(0-68 days) after the MRA. Three-dimensional TOF-MRA, CE-TR-MRA, and DSA images were evaluated for presence and size of residual aneurysm, and endolumenal stent diameter, with DSA used as the reference standard.

Results

Twenty of 21 CE-TR-MRA studies were of diagnostic quality; one patient had a nondiagnostic MRA due to artifact from a clipped contralateral aneurysm. Three aneurysms represented recurrence following prior endovascular coiling. The median MRA follow-up period was 177 days following pipeline placement (49-218 days). The sensitivity and specificity, positive predictive value (PPV), and negative predictive value (NPV) of the 3D-TOF-MRA relative to DSA for detection of residual/recurrent aneurysm filling were 79%/78%/88%/63%, and 95%/78%/90%/88% for CE-TR-MRA relative to DSA. The two aneurysms reported occluded on CE-TR-MRA that were patent on DSA demonstrated only minimal curvilinear filling measuring 1 mm in maximal depth. One aneurysm reported minimal interstitial filling on CE-TR-MRA showed complete occlusion on DSA performed on

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

the same day. A major pitfall of 3D TOF MRA was failure to differentiate T1 hyperintense thrombus and residual aneurysm filling. Both MRA techniques overestimated the extent of narrowing of the pipeline stent lumen, 3D TOF MRA by a mean of 58%, and CE-TR-MRA by a mean of 27%. The figure demonstrates overestimation of stenosis on a CE-TR-MRA MIP versus DSA.



Conclusion
Contrast-enhanced TR-MRA is a promising noninvasive technique for monitoring pipeline-embolized intracranial aneurysms and is more sensitive and specific than 3D-TOF-MRA. Both 3D-TOF-MRA and TR-CE-MRA overestimate the extent of in-stent stenosis.

Second Catheter Angiography after Initially Negative Invasive and Noninvasive Imaging in Patients with Atraumatic Subarachnoidal Hemorrhage

Ringelstein, A.·Mueller, O.·Moenninghoff, C.·Goericke, S. L.·Sure, U.·Forsting, M.·Schlamann, M.
University Hospital Essen
Essen, GERMANY.

Purpose
This study aimed to determine the yield of DSA for the detection of causative vascular lesions in patients with atraumatic subarachnoidal hemmorhage (SAH) and negative initial noninvasive and invasive neurovascular examinations (CTA, DSA and MRA).
Materials & Methods
We retrospectively evaluated 7147 invasive catheter angiographies between 2004 and 2012 from our PACS System. Ninety patients presented with subarachnoidal hemorrhage and repetitive DSA because initial noninvasive and invasive imaging was negative concerning a causative vascular lesion. Two neuroradiologists reanalyzed the initial imaging and the result of repetitive DSA independently to find out if a second DSA might be helpful in detecting an initially occult bleeding source.
Results
Repetitive DSA demonstrated a causative vascular lesion in four patients (4.5%). In all other patients no causative vascular lesion was found. Since the implementation of 3D rotational DSA in 2008 only one more causative vascular lesion was found during repetitive DSA and the rate of initially negative imaging and accordingly the number of necessary reangiographies approximately halved although the number of acute SAH did not change significantly.
Conclusion
Repetitive DSA revealed a cause for SAH after initially negative imaging diagnostics in some rare cases and the detection rate decreased after implementation of 3D rotational DSA. But as these findings have a therapeutic and prognostic impact, we think that a repetitive DSA can be recommended in patients with SAH, even under consideration of the risk of a second invasive diagnostic angiography itself. Interdisciplinary evaluation and double reading of the initial imaging might be helpful to avoid repetitive DSA.

eP-172

Benefit of 3D Rotational Angiography Compared to Conventional Biplanar Digital Subtraction Angiography in Detecting Bleeding Sources after Subarachnoidal Hemorrhage

Ringelstein, A.·Mueller, O.·Goericke, S. L.·Moenninghoff, C.·Sure, U.·Forsting, M.·Schlamann, M.
University Hospital Essen
Essen, GERMANY.

Purpose
In about 85% of patients with subarachnoidal hemorrhage (SAH) a causative vascular lesions can be found during acute imaging diagnostics with CTA and DSA. In 15% the bleeding source cannot be cleared. Usually, a repetitive DSA is mandatory and includes the usual complication risk of an invasive angiography. The present study assesses if 3D rotational angiography may help to avoid a repetitive DSA.
Materials & Methods
From January 2004 till December 2012 we extracted 90 patients with acute nontraumatic SAH and negative initial imaging diagnostics concerning the bleeding source from our PACS system. All patients have received a second angiography on the basis of an interdisciplinary neuroradiologic and neurosurgical conference. Retrospective and independent double reading was performed. From 2004 until July 2008 only 2D DSA was available, since July 2008 until today 3D rotational DSA has been performed in every case during first and second DSA.
Results
In the second DSA, we found four aneurysms in four patients (4/90; 4.5%) that were treated subsequently. During the first 4.5 years of this study 60 patients needed a reangiography compared to 30 patients during the last

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

4.5 years. The number of patients with acute nontraumatic SAH treated in our hospital did not change significantly. During the first phase we found three aneurysms, during the second phase of the study only one.
Conclusion
Using 3D rotational DSA during initial imaging diagnostics helps to reduce false negative results concerning the bleeding source during acute diagnostics and helps to avoid repetitive DSA. The usage of 3D DSA during second angiography does not reveal more aneurysms than conventional biplanar DSA. Three-dimensional rotational DSA should be an essential part of diagnostics after acute SAH.

Transbrachial Coil Embolization of Cerebral Aneurysms in the Anterior Cerebral Circulation with a Novel Sheath Guide for Transbrachial Carotid Cannulation

Iwata, T.·Mori, T.·Miyazaki, Y.·Nakazaki, M.·Takahashi, Y.
Shonan Kamakura General Hospital Stroke Center
Kamakura, JAPAN.

Purpose
Transfemoral approach is a common technique for coil embolization of cerebral aneurysms in the anterior cerebral circulation. However, it is difficult to advance a guiding catheter into the carotid artery through the femoral route in patients with a tortuous aortic arch, an unfavorable supra-aortic takeoff, aortic diseases or occlusion of the femoral artery. The purpose of our study was to report our initial experiences of coil embolization of cerebral aneurysms in the anterior cerebral circulation with a novel sheath guide for transbrachial carotid cannulation.
Materials & Methods
A 6 Fr sheath guide designed specifically for transbrachial carotid cannulation was developed, transbrachial coil embolization for cerebral aneurysms was started in May 2011. Included for analysis were patients who underwent transbrachial coil embolization of cerebral aneurysms in the anterior cerebral circulation from May 2011 to July 2012. Adjuvant techniques, angiographic results, procedural success and periprocedural complications were investigated.
Results
Eighteen patients underwent transbrachial coil embolization of cerebral aneurysms in the anterior cerebral circulation. The locations of aneurysms were the internal carotid artery (ICA) paraclinoid (n = 7), ICA posterior communicating artery (n = 4), middle cerebral artery (n = 3), anterior communicating artery (n = 3) and anterior cerebral artery (n = 1). Transbrachial approach was never abandoned or switched to transfemoral approach in any cases. The stent-assist and balloon-assist techniques as adjuvant ones were used smoothly through the sheath guide in three patients and in nine patients, respectively. At the end of the coil embolization, complete occlusion was in 12 patients and near complete in six. All procedures were successful through the brachial route. Neither periprocedural complications nor access-site related complications occurred. Patients were free on their beds immediately after coil embolization even during hemostasis.
Conclusion
Transbrachial coil embolization of cerebral aneurysms in the anterior cerebral circulation with a novel sheath guide for transbrachial carotid cannulation was safe, feasible and useful.

Vision Outcomes and Major Complications after Endovascular Coil Embolization of Ophthalmic Artery Aneurysms

Durst, C.[1]·Nguyen, Q.[2]·Gaughen, J.[1]·Patrie, J.[1]·Jensen, M.[1]·Evans, A.[1]
[1]University of Virginia, Charlottesville, VA, [2]Franklin Square Hospital, Baltimore, MD.

Purpose
Ophthalmic artery aneurysms are difficult to treat surgically due to their location near the clinoid process and the proximity of the optic nerves. Furthermore, aneurysms arising from either the ophthalmic artery or the ophthalmic segment of the internal carotid artery have been known to cause visual disturbances or eye pain. The advent of endovascular treatment techniques has provided an alternate method for the treatment of these aneurysms. This paper aims to describe the inherent risks of endovascular treatment of these aneurysms and the likelihood of improvement or degradation of visual disturbances or eye pain after treatment.
Materials & Methods
A retrospective study identified 91 patients (78 female and 13 male) who underwent coil embolization of an ophthalmic artery aneurysm or an aneurysm of the ophthalmic segment of the internal carotid artery. All treatment data, immediate and long term imaging outcomes, and immediate and long term clinical outcomes were recorded.
Results
There was no difference in the rate of major complication between aneurysms arising from the ophthalmic artery and those arising from the ophthalmic segment of the internal carotid artery. Patients who presented with hemorrhage are more likely to have a major complication ($p = 0.003$). Patients with hypertension tended to have more major complications, though this did not reach statistical significance ($p = 0.100$). Of the 65 patients with greater than six months of follow-up imaging, 19 had a

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

recurrence. The maximum dimension of the aneurysm dome (p = 0.003), the aneurysm neck (p = 0.031), and the dome to neck ratio (p = 0.002) correlate with the rate of recurrence. Patients who presented with hemorrhage were more likely to have an aneurysm recurrence (p = 0.018). When patients presented with a recurrence, they were more likely to present with a subsequent recurrence (p = 0.032). Patients who were symptomatic prior to treatment were likely to improve after treatment while those who were asymptomatic were likely to stay that way (p = 0.029). This is contrary to what has been published previously. Those with a smaller aneurysm neck diameter were more likely to have symptomatic improvement (either improvement in visual disturbance or eye pain) after treatment (p = 0.035).
Conclusion
Complication rates may be stratified according to the presence or absence of subarachnoid hemorrhage with hypertension possibly being a smaller contributor. The risk of recurrence after endovascular treatment also correlates with the presence or absence of hemorrhage and increases with the size of the aneurysm. Perhaps most importantly, patients who present with symptomatic visual disturbance or eye pain have significant improvement after treatment.

Endovascular Treatment of Small Wide-Neck Intracranial Aneurysms: Which Treatment Now?

Redjem, H.·Blanc, R.·Pistocchi, S.·Bartolini, B.·Nishido, H.·Piotin, M.
Fondation Adolphe De Rothschild
Paris, FRANCE.

Purpose
The aim of this study was to evaluate angiographic and three months clinical outcomes after endovascular treatment of little wide-neck aneurysms ≤ 3 mm.
Materials & Methods
Beetween January 2002 and November 2011, 1627 consecutive patients with 1963 aneurysms have been treated in our center by endovascular treatments. One hundred six aneurysms (33 ruptured) measuring less than 3 mm have been treated in 103 patients. Among them, 11 aneurysms have been treated by flow-diverter stents. We report procedural complications, immediate angiographic results and clinical and angiographic outcomes.
Results
No hemorrhagic or thrombo-embolic complication has been reported in the group of the aneurysms treated with flow diverter. In the group of aneurysms treated by coils or stent-assisted coiling, we report five (4.8%) vascular or aneurysm bag perforations and two (1.9%) thrombo-embolic complications. There were three (2.9%) permanent and three (2.9%) transient neurologic complications among which two deaths have been attributed to the intervention.
Conclusion
Endovascular treatment of small wide-neck intracranial aneurysms is not associated with a higher rate of complications than for larger ones despite a higher risk of vascular perforation. Treatment with stent-flow diverters may be a good choice for lesions of the "blister-like" type and offers a new approach in the endovascular treatment of microaneurysms.

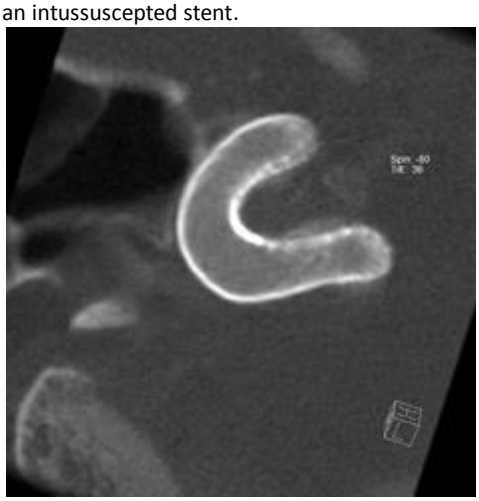
Dyna-CT Atlas of Pipeline Device

Massari, F.·Chaudry, I.·Spiotta, A.·Miranpuri, A. S.·Hawk, H. E.·Turner, R. D.·Turk, A. S.
Medical University of South Carolina
Charleston, SC.

Purpose
A successful Pipeline (PED) (Covidien, Irvine, CA, USA) embolization procedure is dependent upon understanding the anatomical relations of the deployed PED to the parent vessel, aneurysm neck and surrounding anatomical structures, ensuring adequate neck coverage with the PED. We have created an Atlas of IA DYNA CT PED deployment demonstrating adequate wall apposition, poor wall apposition, neck coverage, poor apposition between telescoping stents and PED complications such as PED intussusception.
Materials & Methods
High anatomical detail of the PED in relation to the parent vessel, aneurysm neck and adjacent structures can be difficult to obtain with conventional or three dimensional (3D) rotational angiography. To obtain this detail, an intra-arterial dilute (20%) contrast-enhanced DYNA CT (Siemens, Forchheim, Germany) was performed using an Artis Zee flat panel biplane angiographic system with commercially available software and reconstructed on a commercially available Leonardo workstation (Siemens Medical Solutions, Erlangen, Germany). The images obtained give exquisite detail of the PED itself, its apposition to the parent vessel wall, neck coverage as well as complication of PED deployment.
Results
At our institution a total of 104 PEDs have been deployed. A total of 21 IA contrast-enhanced DYNA CTs (ICE DYNA CT) have been performed to evaluate PED deployment. In analyzing the acquired ICE DYNA CTs we have created an atlas of PED deployment, complication and artifacts. The atlas created demonstrates cases of incomplete stent apposition due to poor conformability of the PED due to tortuous cerebral vasculature, as well as stent deformation such as flattening of the stent midsection, kinking, or inward crimping of the proximal and distal ends, as well as

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

an intussuscepted stent.



Conclusion
Our study presents an illustrative case atlas, in which information added by the ICE DYNA CT improves our understanding and visualization of PEDs that is superior to DSA an 3D DSA. It enhances understanding of stent behavior in clinical practice and improves the efficacy and safety of intracranial deployment of the PED device.

Stent Assistance as a Packing Density Determining Factor in Endovascular Aneurysmal Coiling

Darwish, M. M. N.·Ku, A.·Aziz, K. M.·Williams, R.
Allegheny General Hospital
Pittsburgh, PA.

Purpose
Techniques for aneurysmal coiling have been greatly improved recently and now they involve hydrocoils, balloon remodeling or stent assistance. We here compare the stent assistance to other methods regarding packing densities of the coiled aneurysms. Our purpose is to compare the packing densities of the aneurysms coiled with stent assistance versus those coiled with coils alone and/or with balloon assistance.
Materials & Methods
This is a retrospective study of our 354 interventionally coiled aneurysms. We have divided these aneurysms into ruptured and unruptured aneurysms and each group has been further subdivided into those treated with either Hydrogel or bare platinum coils. Volume fill is calculated by the Angiocalc program.
Results
As shown in the table, although the aneurysms treated with stent assistance were of larger sizes than those treated with coils alone or coils with balloon remodeling, they had greater packing densities especially if the stents were used with hydrogel coated coils. This may be explained technically by the fact that the stent acts as a barrier between the parent artery and the intra-aneurysmal coiling mass allowing insertion of more coil loops without fearing the backward herniation in the main vessel especially in the wide-necked aneurysms. Another unproved notice is that the stent may sometimes reduce the flow inside the aneurysm, especially with double stenting, and thus helps stagnation and intra-aneurysmal thrombosis.

		Bare Platinum Coils		Hydrogel Coated Coil	
No. of assisted coiling cases of treated aneurysms	Total	182		172	
	Differential	Ruptured	Unruptured	Ruptured	Unruptured
		95	87	85	87
No. of assisted coiling cases	Coils alone	70	35	56	14
	Balloon	22	33	17	21
	Stent	3	19	12	53
Aneurysmal Size (in mm^3)	Avg. (/ group)	148.98	165.55	272.64	424.68
	Avg. (Total)	156.75		349.55	
	Coils alone	176.04	189.36	298.78	452.9
	Balloon	59.71	88.82	203.74	164.2
	Stent	172.09	262.57	248.26	517.5
Percentage Of Packing Volume (%)	Avg. (Total)	49.20%		82.20%	
	Avg. (/ group)	46.37	52.36	80.64	83.72
	Coils alone	44.24%	47.26%	81.43%	80.88%
	With balloon remodeling	48.61%	53.58%	72.95%	83.64%
	With Stent Assistance	80.26%	59.48%	87.83%	83.58%

Conclusion
The use of stent assistance specifically increases the density of packing volumes when compared to coils alone or even coils with balloon remodeling techniques. For large aneurysms, we recommend hydrogel coated coils with stent assistance.

TOPSAT: A Single-Center Randomized Controlled Feasibility Trial of Management Strategies in Poor-Grade Aneurysmal Subarachnoid Hemorrhage Patients

Mitra, D.[1]·Gholkar, A.[1]·Jayakrishnan, V.[1]·Gregson, B.[2]·White, P.[2]·Vincent, A.[1]·Mitchell, P.[1]
[1]Royal Victoria Infirmary, Newcastle upon Tyne, UNITED KINGDOM, [2]Newcastle University, Newcastle upon Tyne, UNITED KINGDOM.

Purpose
Management of WFNS good-grade aneurysmal subarachnoid hemorrhage (SAH) is well established and

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

based on high quality evidence. However for poor-grade SAH the evidence is primarily from small retrospective case series. We report a single-center randomized controlled pilot feasibility trial of two management strategies: early endovascular aneurysm treatment (early treatment arm) or aneurysm treatment after neurologic recovery (conventional treatment arm). The study - Treatment Of Poor-Grade Subarachnoid Hemorrhage Trial (TOPSAT) - looks at the feasibility of randomization, recruitment rate, safety profile including mortality rate and functional outcome.

Materials & Methods

Hemodynamically stable adult patients admitted to ITU with WFNS grade IV or V SAH were eligible for the study. Assent for the trial was obtained from next of kin. Major exclusion criteria were signs of irreversible brain death, patients requiring immediate clot evacuation, pure intraventricular hemorrhage, age over 75 years and lack of equipoise. Patients were randomized within 24 hours of admission to ITU on an intention-to-treat basis. Patients in the early treatment arm received endovascular treatment of aneurysm within 24 hours of randomization. Patients in the conventional arm received aneurysm treatment (endovascular/surgical as appropriate) after neurologic recovery to WFNS grade III or better. The randomization process ensured even distribution of patients with significant hydrocephalus in the two arms. Functional outcome was measured by Modified Rankin's Score (MRS) at discharge and at six months.

Results

Fifty-one patients were screened for the trial over a 29-month period. Fourteen patients met the eligibility criteria and eight were randomized. In the other six, assent for the trial was not obtained. The recruitment rate for the trial was 57% of patients eligible and 16% of patients screened. Main reasons behind ineligibility for the trial were improvement of WFNS grade to III or better before randomization (21.6%), requirement for emergency clot evacuation (13.5%), hemodynamic instability (13.5%) and delay before randomization (13.5%). Five patients were randomized to early treatment arm and three patients to conventional treatment arm. Six patients in the study died (mortality rate 75%). Two patients had good outcome (MRS 1 in one and MRS 0 in another). There were no endovascular procedure-related adverse event and no unexpected nonprocedure-related adverse event.

Conclusion

Many centers currently offer early endovascular treatment to a significant number of poor-grade SAH patients. Efficacy of this approach needs to be established through a randomized controlled trial. Our experience suggests that such a trial is feasible and safe. However recruitment rate is relatively low due to attrition by factors described above. A multicenter study is necessary to obtain the necessary patient recruitment.

eP-179

Multimodel Treatment of Dural Arteriovenous Fistula with Emphasis on Endovascular Embolization: Single Center Experience

Shahin, G. S.·Marin, H.·Sanders, W.·Kole, M.·Jung, M.
Henry Ford Hospital
Detroit, MI.

Purpose

Definitive treatment of dural arteriovenous fistulas (DAVFs) implies total disconnection of the fistula, and traditionally was done surgically. Endovascular treatment of DAVF had consistently gained ground during the last seven years, in particular since the widespread use of ethylene polyvinyl alcohol as embolic agent. We performed a retrospective analysis of our patients with DAVF, in order to identify the rate and predicting factors for endovascular cure.

Materials & Methods

Total of 40 consecutive patients referred to us with diagnosis of cerebral DAVF were anlayzed. Demographics, presenting symptoms, angiographic architecture, treatment and followup were reviewed. We excluded patients with cavernous carotid fistula and pial AVM.

Results

Total of 13 patients presented intracranial hemorrhage, 10 with pulsatile tinnitus, one with headache, 16 with various neurologic deficits (vertigo, memory loss, hydrocephalus, cranial nerve deficits). We have classified DAVFs by location in convexity (n = 7), anterior cranial fossa (n = 2), middle cranial fossa (n = 2), transverse/sigmoid sinus (n = 9), petroclival (n = 9), tentorial/vein of Galen (n = 4), posterior fossa (7). By angiography, there were grade I + IIA (n = 6), IIB (n = 7), III (n = 10), IV (n = 14), V(n = 3 patients) according to the Cognard classification. Ten patients were treated with endovascular embolization solely with 60% cure. In 17/24 patients where embolization was used, residual shunting was seen. Total of 14 patients were treated with combination endovascular embolization and surgery. Embolization was not successful in totally eliminating the fistula, because of the large, multihole fistulas in 12/24 patients and inability to position the microcatheter in the the proximity of the fistula site in 5/24 patients. Seven patients were treated with surgery alone and two with radiosurgery. Total of seven patients (presenting with pulsatile tinnitus alone) opted for conservative followup.

Conclusion

Endovascular embolization in combination with surgery are most effective in complete treatment of DAVFs. Embolization alone can be successful in treatment of small DAVFs when the microcatheter is positioned in proximity to the site of the fistula.

KEYWORDS: AVF, Embolization

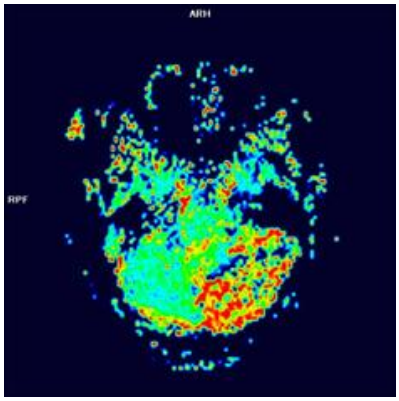
MR Perfusion Findings in Patients with Symptomatic Posterior Fossa Venous Congestion

Hui, F. K.·Dyer, E.·Jones, S.
Cleveland Clinic
Cleveland, OH.

Purpose
Vascular lesions of the brain may result in venous hypertension that may or may not be clinically silent. Headaches, encephalopathy, seizures, infarction and hemorrhage may be associated as sequlae of venous hypertension. Causative factors may include dural sinus or venous thrombosis or arteriovenous fistulae. Developmental venous anomalies have been associated with perfusion abnormalities as well. This report reviews the perfusion findings in three patients with lesions that resulted in venous congestion in the posterior fossa.
Materials & Methods
Retrospective analysis of the case logs of the cerebrovascular center was performed yielding three patients with cerebellar venous congestion. Patient demographic, imaging and clinical information was obtained.
Results
The three patients are summarized in tabular form along with demographic, imaging findings included. One patient harbored a dural arteriovenous fistula of the left tentorium and two patients harbored developmental venous anomalies that drained the majority of a cerebellar hemisphere. The dural fistula was managed with embolization of the diseased sinus, and one of the developmental venous anomalies was treated conservatively given the intermittent nature of low grade, ipsilateral posterior headaches. The third patient was managed with anticoagulation and hydration, given recent development of 10 out of 10 headaches with worsening during valsalva in a patient with a known large venous anomaly. Two weeks following initiation of medical therapy, the patient reported return to baseline levels of discomfort. Imaging in the last case demonstrated high-grade venous outlet stenosis of the venous anomaly.



Conclusion
MR perfusion can help noninvasively assess the degree of venous stasis manifesting with prolonged mean transit time and increased cerebral blood volume. Resolution or improvement in relative perfusion parameters may correspond with clinical improvement. With sufficient experience, it may become possible to differentiate between clinically silent and pathologic developmental venous anomalies as well as assess the malignancy of dural fistulae.

eP-181

Craniovertebral Junction (Occiput-C2) Spinal Arteriovenous Dural Fistulas with Cranial and with or without Spinal Perimedullary Venous Drainage - A Potentially Dangerous Clinical Feature: A Case Series

Puri, A. S.[1]·Hou, S.[1]·Telischak, N.[2]·Thomas, A.[2]·Wakhloo, A.[1]
[1]University of Massachusetts Medical Center, Worcester, MA, [2]Beth Israel Deaconess Medical Center, Boston, MA.

Purpose
Spinal dural arteriovenous fistula (SDAVF) is an abnormal connection between arteries and veins in the dural covering. The venous drainage from these fistulas can be extradural in the suboccipital venous plexus or intradural. The intradural venous drainage is the dangerous variety as it can occur either cranially into the posterior fossa or caudally into the vertebral venous plexus or in both directions. Venous reflux into the posterior fossa can lead to intraparenchymal or subarachnoid hemorrhage. The caudally directed venous reflux can cause venous congestion and subsequent myelopathy. The skull base region, from the occiput to C2, is unique in its location for SDAVFs as both the brain and the spinal cord are at risk. We describe the clinical presentation, angioarchitecture, management and clinical follow up of FOUR cases with skull base SDAVFs and dangerous venous outflows.
Materials & Methods
We performed a retrospective review of the case logs of the University of Massachusetts Medical Center and Beth

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Israel Deaconess Medical Center between July 2011 and November 2012 in order to select patients with angiographically proven SDAVFs at the craniovertebral junction with cranial intradural venous reflux and/or caudal spinal perimedullary venous reflux in order to analyze the angiographic features, treatment strategy and clinical followup.

Results

Patient demographics included one male and three females, age range from 60-65 years. Three patients presented with symptoms likely related to the SDAVF, two with posterior fossa hemorrhage, and one with cervical cord myelopathy. One patient was incidentally discovered during workup and treatment of a ruptured supratentorial aneurysm. Angiography in all patients demonstrated a left-sided SDAVF located at the craniovertebral junction and supplied by the musculospinal branches of the V2 and/or V3 segments of the vertebral artery. The venous drainage in all four cases was into the intradural veins of the posterior fossa. In three cases additional venous reflux into the spinal perimedullary venous system was noticed. Endovascular treatment was attempted in two patients but due to the small size of the arterial feeders, an optimal microcatheter position could not be achieved for a safe liquid embolic injection. Three patients underwent surgical resection of the SDAVF. The two patients with posterior fossa hemorrhages are neurologically intact after surgery. The patient with cervical cord myelopathic symptoms is in a chronic rehabilitation facility. The patient with incidentally discovered SDAVF, treatment has been deferred for an endovascular treatment until she has recovered adequately from her aneurysmal subarachnoid hemorrhage and vasospasm.

Conclusion

This case series of patients with craniovertebral SDAVF with dangerous venous outflow on angiograms shows the potential morbidity of SDAVF and illustrates the need for an early and aggressive surgical or endovascular management to obliterate the arteriovenous shunt.

eP-182

Interest of Using a Spherical Convex Anamorphosis for a Better Understanding of the Angio-Architecture of Brain Arteriovenous Malformations

Clarençon, F.[1]·Maizeroi-Eugène, F.[2]·Gory, B.[3]·Sourour, N.[1]·Bresson, D.[4]·Mounayer, C.[5]
[1]Pitié-Salpêtrière Hospital, Paris, FRANCE, [2]Segmentix, Limoges, FRANCE, [3]Lyon University Hospital, Lyon, FRANCE, [4]Lariboisière Hospital, Paris, FRANCE, [5]Limoges University Hospital, Limoges, FRANCE.

Purpose

To elaborate an algorithm of convex spherical anamorphosis that could be applied on 3D rotational angiography (3D RA) acquisitions for the understanding of brain arteriovenous malformations (bAVMs).

Materials & Methods

The algorithm was elaborated on Matlab software (version R2009b). The data from 3D RA of 12 patients (six males, six females; 10 supratentorial bAVMs; two infratentorial bAVMs) treated with a previously described segmentation algorithm (ASNR 2012). The convex spherical anarmophosis is a barrel distortion that consists to apply a part of a plane surface on a convex hemisphere. This deformation may help to "spread" the nidus and the vessels close to the nidus. Two independent observers applied this algorithm on the volumes (nidus, arteries and veins) derived from the segmentation of bAVMs and semiquantitatively evaluated its quality (poor, fair and good). The number of arterial feeders to the nidus showed by this barrel distortion was compared with the images obtained from 6 f/s DSA in AP, lateral and oblique projections.

Results

The application of the convex spherical anamorphosis was possible in all cases. The quality of the deformation provided was evaluated as good by both observers in most cases. In average, convex spherical anamorphosis could depict one more arterial feeder than the six f/s DSA.

Conclusion

The algorithm of convex spherical anamorphosis elaborated is a promising tool for a better understanding of complex bAVMs.

Combined Treatment of Brain Arteriovenous Malformations with Onyx Embolization Followed by Radiosurgery

Pierot, L.·Kadziolka, K.·Lanoix, O.·Rousseaux, P.
Hopital Maison-Blanche
Reims, FRANCE.

Purpose

The treatment of cerebral arteriovenous malformations (AVMs) is complex, based on embolization, surgery, and radiosurgery, or a combination of modalities. Treatment by Onyx embolization followed by radiosurgery was not evaluated previously. The goal of our study is to evaluate in an homogeneous, monocentric series the long-term clinical and anatomical outcome of patients treated by this combination.

Materials & Methods

From April 2003 to June 2008, 20 patients (11 females and nine males, aged 10 to 55 years) were treated for a brain AVM by Onyx embolization followed by radiosurgery. Arteriovenous malformation size was < 3 cm in seven cases and ≥ 3 cm in 13 cases. Modalities and complications of the procedure were analyzed as well as long-term clinical and anatomical outcome (two - four years after

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

treatment).
Results
Out of 17 patients evaluated by DSA after radiosurgery, 10 had a complete occlusion of AVM nidus (58.8%). Complete occlusion was observed in five of seven Spetzler-Martin grade 1-2 AVMs (71.4%) and in five of 10 Spetzler-Martin grade 3-4 AVM (50.0%). Complete occlusion was observed in four of five AVM with size < 3 cm (80.0%) and six of 12 AVM with size > 3 cm (50.0%). One out of 20 patients had significant worsening of their clinical status (mRS ≥ 2) at long-term followup.
Conclusion
In this series of patients with AVMs treated with Onyx embolization followed by radiosurgery, the safety and efficacy of this treatment combination is quite satisfactory with a 58.8% rate of complete obliteration and a low rate of clinical complications (5.0%).

eP-184

Dose Reduction in Transarterial Melphalan Infusion for Intraocular Retinoblastoma

Cooke, D. L.·Stout, C. E.·Kim, W. T.·Hetts, S. W.·Higashida, R. T.·Dowd, C. F.·Halbach, V. V.·Gould, R. G.
University of California San Francisco
San Francisco, CA.

Purpose
Retinoblastoma (RB) is a rare and curable malignancy affecting the pediatric population. Intravenous chemotherapy is the long-standing delivery method, though intra-arterial (IA) is gaining popularity given the reduced side effects related to systemic administration. Intra-arterial infusion has demonstrated technical feasibility, few procedural complications, and robust tumor response. Given the sensitivity of the target organ, patient age, and secondary tumor susceptibility a premium has been placed on minimizing procedura- related radiation exposure.
Materials & Methods
To reduce patient dose during the IA infusion procedure, a combination of tailored surgical methods, including collimation, single plane usage, reduced source-to-image distance, and exclusion of the lens from the field of view, and customization of the fluoroscopic technique were performed. While the dose rate continued to be controlled by the automatic exposure control, the routine fluoroscopic settings were changed from the standard 7.5 pulses per second and a dose level to the detector of 36 nanoGy per pulse, to a pulse rate of four pulses per second and a detector dose to 23 nanoGy per pulse. The angiographic dose indicators [Reference Point air Kerma (RP) and fluoroscopy time] for cohort of 10 consecutive (12 affected eyes, 30 infusions) were analyzed.
Results
The mean RP per treated eye was 20.1 ± 11.9 mGy with a mean fluoroscopic time of 8.5 ± 4.6 minutes. Review of the data demonstrated three cases with elevated dose relative the mean dose (Figure 1). These outliers represented three different scenarios: 1) Unstable catheter position (treatment five) requiring usage of multiple microcatheter types; 2) External carotid supply (treatment 10) to the ophthalmic artery; and 3) Mixed use of the standard and low-dose settings (treatments 17 and 18) to better visualize the arterial anatomy. Subsequent treatments (treatments 15 and 22) in the patient with external carotid to the ophthalmic artery regressed toward the mean dose.

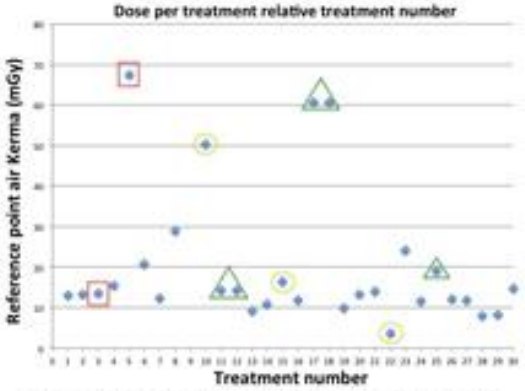

Figure 1. Scatter plot of treatment number relative reference point air Kerma (mGy) per treated eye. Treatments 3 and 5 (red), 11, 12, 17, 18, 25, 26 (green), and 1–, 15, and 22 (yellow) represent the three patients treated at different time points. Treatments 11-12 and 17-18 were performed at the same time given the patients' bilateral disease. The four highest doses represented three different scenarios: 1) unstable catheter position (treatment 5) secondary to an acute ophthalmic artery origin requiring usage of multiple microcatheter types; 2) External carotid supply (treatment 10) to the ophthalmic artery; and 3) Mixed use of the standard and low dose settings (treatments 17 and 18) to better visualize the arterial anatomy.

Conclusion
Ophthalmic arterial melphalan infusion is a safe and effective means to treat retinoblastoma. Modification to contemporary fluoroscopic systems combined with parsimonious fluoroscopy can minimize radiation exposure.

C-Arm CT Measurement of Cerebral Blood Volume: Optimization of Injection Protocols and Steady State Analysis

Caroff, J.[1,2]·Jittapiromsak, P.[2]·Benachour, N.[2]·Pasco Papon, A.[1]·Ruijters, D.[3]·Aubé, C.[1]·Spelle, L.[2]·Moret, J.[2]
[1]CHU Angers, Angers, FRANCE, [2]Beaujon Hospital, Paris, FRANCE, [3]Philips, Best, NETHERLANDS.

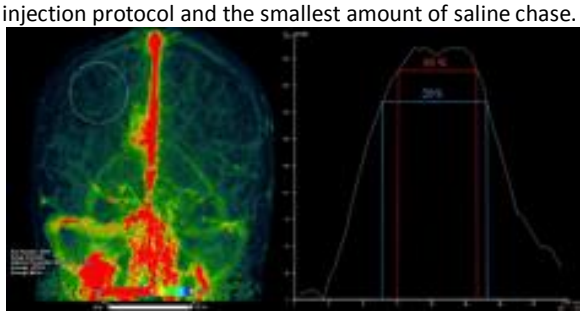
Purpose
Cerebral volume measurement by flat panel detector CT in the angiography suite is a promising tool for patient management during endovascular early stroke therapy. A steady state of contrast agent distribution is mandatory during acquisition. To the best of our knowledge, this was the first time that steady state parameters were studied in clinical practice.
Materials & Methods

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Before the cerebral blood volume study, test injections were performed and analyzed to determine a customized acquisition delay from injection time for each patient. Three different injection protocols were used including peripheral and central venous injections. Seventy-two mL of contrast agent material was administrated at an injection rate of 4.0 mL/s followed by a 72 or 20-mL saline bolus at the same injection rate. Twenty-four patients were treated for different types of neurovascular diseases. From test injections and time attenuation curves were calculated: maximal attenuation, steady state length and delay from injection.

Results

With a 10% threshold from maximum attenuation, average steady state duration was less than 10 seconds. Maximum attenuation values and steady state durations with minimal delay variations were obtained with central injection protocol and the smallest amount of saline chase.



Conclusion

With clinically acceptable contrast agent volumes, steady state is a brief condition thus fast rotation speed acquisitions are needed. From this study it is possible for most patients to establish a probabilistic acquisition delay and then to avoid test injections.

eP-186

Update on the UK Flow Diverter Registry

White, P. M.[1]·Molyneux, A.[2]
[1]Institute for Ageing & Health, Newcastle upon Tyne, UNITED KINGDOM, [2]Oxford University, Oxford, UNITED KINGDOM.

Purpose

All flow diverters deployed in UK from 01/01/2010 have been entered into a prospective national audit. Audit is designed to determine procedural safety, early efficacy and medium term clinical outcome. Primary outcome is the modified Rankin score at one year and secondary outcomes are procedural complication rates, change in Rankin and angiographic occlusion.

Materials & Methods

All 31 UK neuroscience centers were contacted. Twenty-six centers responded, five centers did not respond (but three of these don't have an INR service). Two of responders have INR service but indicated they don't use FDs. Twenty-four active centers enrolling into registry. NICE guidelines now mandate use of Registry for all PED cases undertaken in the UK.

Results

We will present demographic and procedural data on the first 200 patients enrolled and data as it becomes available on 12-month followups. Two hundred sixteen aneurysms were treated in total. Eighty-seven percent were not ruptured recently (nearly all unruptured). Age range: 25-82 years, 57% <60 years, 75% female. Average number of FDs used was 1.7 (range 0-8) with more than one device used in 70 patients. Aneurysm type - 66% were saccular, 10% fusiform, 22% giant, 5% blister. Aneurysm location - 20% cavernous ICA, 60% other ICA and 8% posterior. Twelve percent were small, 21% medium, 45% large, 22% giant. Most were wide necked (79%). Forty-five technical problems were encountered (>1 in some patients). There were three periprocedural infarcts, eight cases of parent vessel occlusion and/or flow diverter thrombosis (three felt unrelated to FD device). There were nine "periprocedural" bleeds (within 30 days) - five first bleeds from target aneurysm, three cases of vessel perforation, one remote parenchymal bleed (ipsilateral). There were four cases of delayed hemorrhage - one from aneurysm (unruptured), two ipsilateral and one combined contralateral/ventricular bleed. Thirty-day mortality was 4.5% - but 4% in not recently ruptured versus 10% in recently ruptured aneurysms. There were five cases of progressive cranial nerve palsy. Eighty-two percent were discharged home. Clinical status at discharge was improved 10%, unchanged 76% and worse 10%.

Conclusion

This is a work in progress. However a National Registry of novel devices within the INR field is perfectly feasible. In the absence of RCTs, a comprehensive prospective Registry is perhaps the best way to rapidly establish safety and obtain some idea of device efficacy. An independent professionally run Registry may well be the optimum way to undertake postmarketing surveillance.

Phase-Contrast Synchrotron Radiography of Cerebral Protection Device Retrieved after Carotid Artery Stenting: Feasibility as ex vivo Evaluation of Device-Captured Embolic Debris

Youn, S.[1]·Kim, H.[1]·Kim, H.[2]
[1]Daegu Catholic University Medical Center, Daegu, KOREA, REPUBLIC OF, [2]Daegu Catholic University Medical School, Daegu, KOREA, REPUBLIC OF.

Purpose

To demonstrate the feasibility of phase-contrast synchrotron radiography as a tool for evaluating the embolic debris captured on cerebral protection device

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

(CPD) retrieved after carotid artery stenting (CAS).
Materials & Methods
Five patients (four males, median age, 66 years; range, 55-82 years) with severe carotid artery stenosis underwent CPD-protected CAS. After CAS, the retrieved CPDs were emulsified in 4% formalin, and placed in front of synchrotron beam from 7B2 beamline at Pohang Light Source (PLS, Pohang, Korea). The 600 images of phase-contrast radiography were obtained by rotating CPD 360°. The three-dimensional reconstructed images were segmented into the embolic debris and CPD by visual analysis. Total volume of emboli was calculated by summing up each volume of emboli per scanning level. The surface area covering membrane pore was counted seen from outer surface, and the percentage of covered area was calculated.
Results
Embolic debris were clearly demonstrated within pore, outer and inner surface of CPD. The mean total volume of embolic debris was 538.832 x 10^{-6} mL (range, 225.275-965.484 x 10^{-6} mL). The average 61.46% of them were located at apical one third of CPD. The average 20.84% of the pore area were covered by the debris.
Conclusion
Phase-contrast synchrotron radiography allows us to better understand the detailed microscale appearance of debris with its quantitative information. The debris at outer surface may imply the potential risk of embolization during CAS, and necessitate modifying the design of CPD and procedural steps.

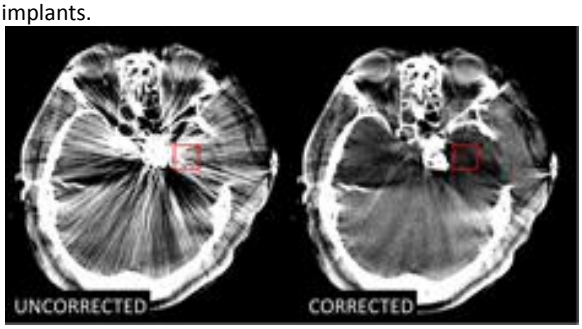
Metallic Artifacts Reduction of Post-Therapeutic Flat-Panel Detector CT Images

Hung, S.[1,2]·Lin, C.[1,2]·Guo, W.[1,2]·Wu, C.[1,2]·Luo, C.[1,2]·Chang, F.[1,2]·Chu, W.[1,2]
[1]Taipei Veterans General Hospital, Taipei, TAIWAN,
[2]National Yang Ming University, Taipei, TAIWAN.

Purpose
Most of angiography suites currently used for diagnostic and interventional neuroradiology are equipped with flat detectors, by which flat detector CT (FD CT) has been widely used. However, in FD CT, the artifacts caused by metallic implants obscure their surrounding structures-of-interest and degrade the imaging quality. We aimed to evaluate the efficacy of reducing the metallic artifacts in FD CT by a postprocessing method.
Materials & Methods
We retrospectively reprocessed FD CT scan volumes of 42 patients. The patients were treated with endovascular coiling (31/42), liquid embolization (9/42), or shunting surgery (2/42) since January 2009. The imaging slice of FD CT that was impaired worst by metallic artifacts was chosen as a target slice. A 1.5 x 1.5 cm^2 ROI was placed, respectively, on the target slice at the vicinity of metallic implants and the adjacent metallic artifact-free slice (as a control) to evaluate the imaging quality before and after applying a metallic artifacts reduction (MAR) prototype software (Siemens Healthcare). The range and standard deviation of CT densities in Hunsfield unit (HU) of the ROI were used as an indicator of imaging quality and noise for the current study. Two experienced neuroradiologists scored the images with consensus.
Results
The metallic artifacts were qualitatively reduced in all patients (Figure). Quantitatively, the range of HU and noise were reduced by 88% and 85% in 31 patients treated by coiling +/- stenting, 69% and 74% in nine patients by liquid embolization, and 70.1% and 60% in two patients by shunting surgery as compared with that before applying MAR. Of 31 patients treated with coiling, the noise reduced by 84.8%, 81.8%, 74.7% in supratentorial, skull base/juxtasellar regions, and posterior fossa by location of metallic implants respectively. The range of HU and noise increased by 30% in control slices after applying MAR ($P < .05$), irrespectively of the types and locations of metallic implants.



Conclusion
Artifacts, stemmed from metallic implants, in FD CT are feasibly and effectively reduced by postprocessing software. The reduction of artifacts significantly improves imaging quality both qualitatively and quantitatively for clinical interpretation and application.

Enhanced, Rapid Occlusion of Carotid and Vertebral Arteries Using the Amplatzer Vascular Plug II: The Duke Cerebrovascular Center Experience in Eight Patients with 22 AVP II Devices

Mihlon, F.·Agrawal, A.·Nimjee, S.·Ferrell, A.·Zomorodi, A.·Smith, T.·Britz, G.
Duke University Hospital
Durham, NC.

Purpose
Therapeutic embolization of the common carotid artery (CCA), internal carotid artery (ICA), and vertebral artery

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

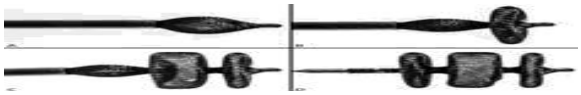
(VA) is necessary in the treatment of a subset of chronic arteriovenous fistulas (AVF), hemorrhages, highly vascularized neoplasms prior to resection, and giant aneurysms. There are currently no reports of the use of the Amplatzer Vascular Plug II (AVP II) to occlude the CCA, ICA, or VA. This article is a case series reporting the Duke Cerebrovascular Center experience using the AVP II in neurointerventional applications.

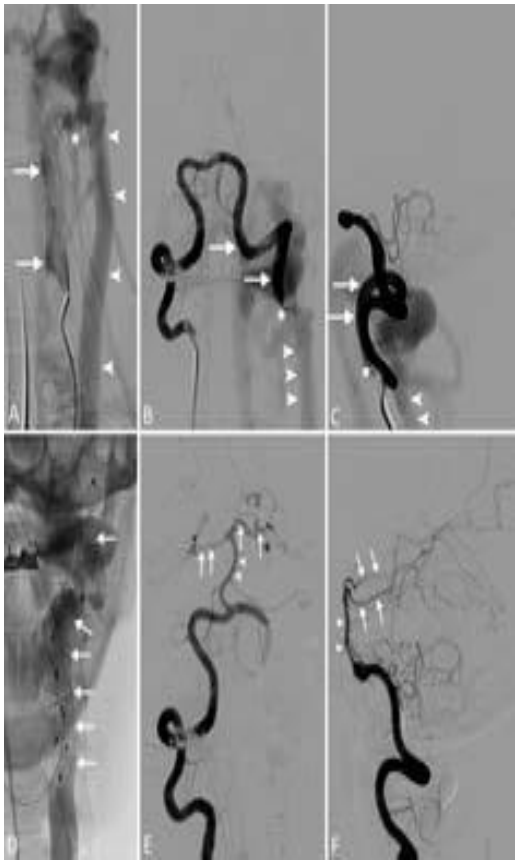
Materials & Methods

This case series is a retrospective review of all of the cases at Duke University Hospital where an AVP II was used in the CCA, ICA, or VA up to September 2012. The AVP II often was used in conjuction with embolization coils or as multiple AVP IIs deployed in tandem.

Results

Eight cases meeting criteria were performed between 2010 and 2012. These included two chronic VA to internal jugular (IJ) AVFs, one hemorrhagic CCA-IJ AVF secondary to invasive head and neck squamous cell carcinoma, one ICA hemorrhage secondary to invasive head and neck squamous cell carcinoma, one ICA hemorrhage secondary to trauma, one ruptured ICA aneurysm, one giant petrous ICA aneurysm, and one case of cervical vertebral sarcoma requiring preoperative VA embolization. Successful occlusion of the target vessel was achieved in all eight cases. There was one major complication that consisted of a watershed distribution cerebral infarct; however, this was related to emergent occlusion of the ICA in the setting of intracranial hemorrhage and not necessarily a problem intrinsic to the AVP II.





Conclusion

The AVP II is relatively large, self-expanding vascular occlusion device that safely allows enhanced, rapid take-down of carotid and vertebral arteries with low risk of distal migration.

Cost Analysis of Aneurysmal Repair by Endovascular Coiling versus Flow Diversion

Nadarajah, M.
National Neuroscience Institute Singapore
Singapore, SINGAPORE.

Purpose

Flow diverters enable intracranial aneurysmal repair without the need to enter the aneurysmal sac. Concerns however have been raised regarding the cost compared to coiling techniques. The aim of this study was to evaluate the relative costs for different aneurysm sizes to ascertain if different sizes are more cost effectively treated by a particular method to establish which aneurysms are most cost effectively treated by each method.

Materials & Methods

Patients undergoing aneurysmal repair at two neurovascular referral centers between September 2005

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

and August 2010 were included, bar patients who underwent coiling for recurrences of prior microneurosurgical clipping. These aneurysms were stratified into three size groups. The average and median number of coils or flow diverters and the average and median costs of treatment of each size category was calculated.
Results
Four hundred twenty-nine aneurysms were treated. Of these, 409 were coiled with or without assist devices. Forty-eight percent fell under Group A (<7 mm), 36% under Group B (7-12 mm) and 16% under Group C (>12 mm). Twenty aneurysms were flow diverted, and of these 14 were treated de novo, five previously coiled, and one previously clipped. Twenty percent belonged in Group A, 25% in Group B and 55% in Group C. The highest procedural costs in the coiling group were Group C aneurysms requiring stent assistance with an average of $24,563 (median $23,860). Using flow diversion, the average was $24,650 (median $16,490).
Conclusion
Given the price parity threshold crossed for aneurysms >12 mm requiring stent assistance and the relative ease of the flow diverter technique, we suggest that flow diversion should be considered the first-line treatment for aneurysms in this category.

eP-191

Use of a Semipermeable Mesh Implant for Treating Painful Osteoporotic Vertebral Compress Fractures of the Thoracic and Lumbar Spine

Ortiz, A.[1]·de Venecia, C.[1]·Patel, B.[2]
[1]Winthrop University Hospital, Mineola, NY, [2]Stony Brook University School of Medicine, Stony Brook, NY.

Purpose
To assess the efficacy of a semipermeable mesh implant (Algea Therapies) in the treatment of painful thoracic and lumbar osteoporotic vertebral compression fractures.
Materials & Methods
Patients with painful thoracic and lumbar osteoporotic vertebral compression fractures which were refractory to conventional medical management and less than three months of age were considered possible candidates for this vertebral augmentation technique. Patients were excluded from this procedure if the fracture was chronic (greater than three months) if the vertebral pedicle could not accommodate the instrumentation and if the vertebral body height loss was more than 60%. Data recorded for the procedure included patient age, gender, fracture type (using the Magerl classification), fracture level, mesh stent size, amount of cement injected, cement extravasation, complications and pre and postprocedure pain scores and Oswestry Disability index scores.
Results
Nine patients were included in this study; seven females and two males, with an average age of 76.2 years. Each patient had one level treated with the mesh implant; two thoracic levels (T11 and T12) and seven lumbar levels (L1, L2 or L3). Anterior column with superior endplate fractures were treated. The 10 x 15 mm implant was used in six treated vertebrae, including the two thoracic vertebrae; the 10 x 20 mm implant was used to treat two lumbar vertebrae and a 10 x 25 mm implant was used to treat an L1 vertebra. An average of 2 mL of acrylic bone cement was injected and there was no fluoroscopic evidence of cement leakage. No patient-related complications were seen and there were no device failures. All patients, followed to at least three weeks, have shown major pain relief.
Conclusion
Vertebral augmentation with a semipermeable mesh stent implant can be used to effectively and safely treat osteoporotic vertebral compression fractures within the lower thoracic and lumbar spine.

KEYWORDS: Vertebral augmentation

eP-192

Chronic Occlusion of the Vertebrobasilar Vessels with Acute Clinical Deterioration: Endovascular Treatment and Clinical Outcome

Aguilar-Pérez, M.[1]·Kurre, W.[1]·Fischer, S.[1]·Niehaus, L.[2]·Bäzner, H.[1]·Schmid, E.[1]·Henkes, H.[1]
[1]Klinikum Stuttgart, Stuttgart, GERMANY, [2]Klinikum Winnenden, Winnenden, GERMANY.

Purpose
Chronic occlusion of the vertebrobasilar vessels may cause acute or chronic brainstem, cerebellar and cerebral ischemia, especially in the case of profound arterial hypotension or dehydration, which may cause failure of collateral blood supply. The spontaneous prognosis of this condition is known to be poor. These chronic occlusions, however, are mostly considered unsuitable for endovascular recanalization. The purpose of this study was to evaluate the efficacy of reopening a chronically occluded vertebrobasilar vessel during acute decompensation and describe technical issues occurring during the procedure and their potential solutions.
Materials & Methods
We retrospectively reviewed all patients who underwent endovascular recanalization of a chronic vertebrobasilar occlusion in our institution. All patients presented with acute clinical deterioration or with medically refractory symptoms and were treated with a combination of segmental balloon dilatation and oversized self-expanding stent deployment. Technical success was defined as the ability to reopen the chronically occluded vessel and improve the antegrade perfusion of the basilar artery. Clinical outcome was measured as mRS score.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Results
Endovascular recanalization was attempted in 24 patients; recanalization was performed successfully in 21 of the 24 cases (87.5%). There were two procedural complications (8%): one vessel perforation during the catheterization and one retroperitoneal hemorrhage. After the procedure, eight patients were stable (33%), 13 patients improved (54%), and four patients were worse (16%). The mean angiographic followup was 16.4 months. Seven patients developed significant in-stent stenosis during this period, which was treated successfully with angioplasty and stenting.
Conclusion
This limited experience reveals that recanalization of chronically occluded vertebrobasilar arteries is technically feasible with current endovascular methods. These procedures can be challenging, they carry substantial risks and should be reserved for patients with medically refractory symptoms.

KEYWORDS: Acute basilar artery, Recanalization, angioplasty and stenting

Pediatric Posterior Circulation Artery-to-Artery Thromboembolic Strokes Caused by Cervical Rotation Induced V3 Segment Vertebral Artery Dissection

Stout, C.·Kim, W.·McSwain, H.·Cage, T.·Cooke, D.·Fullerton, H.·Fox, C.·Lawton, M.·Hetts, S.·Higashida, R.·Dowd, C.·Halbach, V.
University of California San Francisco Medical Center
San Francisco, CA.

Purpose
Pediatric posterior circulation stroke is a rare cerebrovascular disease. The intimate relationship of the vertebral artery (VA) to the cervical spine, and the dynamic anatomical changes they undergo with head rotation (HR), predispose to rotational vascular disease, an idea first proposed by de Kleyn and Versteegh (1933). Vertebral artery dissection initiated by traumatic HR was first proposed by Swartz et al (1956). Since then, VA dissection from less traumatic and/or atraumatic HR has been reported including during swimming, archery practice and yoga. Approximately 53% of reported pediatric idiopathic VA dissections localize to the V3 VA segment (Fullerton et al., 2001), just distal to its exit from the C2 transverse foramen, as it wraps around the C1-C2 joint. In five pediatric patients who presented with progressive posterior circulation strokes and suggestion of VA dissection on cross-sectional imaging, we performed arteriography with HR to evaluate how cervical rotation can cause extrinsic compression and occlusion of this vulnerable segment of the VA, leading to dissection and artery-to-artery thromboembolism.
Materials & Methods
To safely use HR cerebral arteriograms to evaluate our patients, the maximal normal range of HR was established prior to induction of anesthesia, contralateral HR during arteriograms was brief, blood pressure under anesthesia was carefully controlled and, when appropriate, patients were anticoagulated with heparin. Posterior circulation arteriograms were performed first to evaluate for distal branch occlusions, followed by head neutral and HR VA arteriograms. 3D rotational arteriograms helped to evaluate the regional anatomy.
Results
In five sequential pediatric patients with posterior circulation strokes and suggestion of focal dissection at the proximal V3 VA segment, posterior circulation arteriograms demonstrate diffuse vertebrobasilar branch occlusions consistent with artery-to-artery embolic disease. Cervical VA arteriograms show subtle focal irregularity/dilation, some with superimposed intimal flaps, consistent with dissections of varying chronicity. Contralateral HR causes focal VA occlusion at the dissection site that is fully reversed with return to neutral head position. In several cases, each VA showed occlusion on contralateral HR. Many of these findings can be demonstrated on MRI/MRA and CT/CTA.

Conclusion
Focal extrinsic compression and occlusion of the proximal loop of the V3 VA segment at the limits of HR is a mechanism for dissection that acts as a nidus for posterior circulation thromboembolic strokes. This disease process, likely more prevalent than previously recognized, has characteristic findings on HR cerebral angiography, some of which can be seen on cross-sectional imaging.

Outcomes of Mechanical Thrombectomy for Posterior Circulation Strokes: A Study of the Nationwide Inpatient Sample 2006-2010

Brinjikji, W.·Rabinstein, A. A.·Lanzino, G.·Kallmes, D. F.·Cloft, H. J.
Mayo Clinic
Rochester, MN.

Purpose
Acute posterior circulation occlusions are associated with high morbidity and mortality rates. Many studies have demonstrated that recanalization of posterior circulation occlusions using mechanical thrombectomy can improve patient outcomes. To date, there exist no large series of outcomes for patients with posterior circulation occlusions undergoing mechanical thrombectomy. We evaluated a large administrative database to determine trends and outcomes in the use of mechanical thrombectomy in patients with posterior circulation strokes.
Materials & Methods
Using the Nationwide Inpatient Sample, we evaluated outcomes of patients treated for acute ischemic stroke in the United States from 2006-2010. Patients who suffered acute ischemic stroke and underwent endovascular clot retrieval were selected. Those patients with posterior circulation occlusions were identified using International Classification of Disease 9 Codes 433.00, 433.01, 433.20, and 433.21 (occlusion of basilar artery with and without infarction and occlusion of vertebral artery with and without infarction). Primary outcomes were morbidity (discharge to a long-term facility) and mortality. Secondary outcomes were length of stay and intracranial hemorrhage (ICH) rate. Multivariate logistic regression analysis was performed to determine independent predictors of mortality. Variables included in this analysis were occlusion location (anterior versus posterior), gender, race, age, Charlson Co-morbidity Index, presence of intracranial hemorrhage and tissue plasminogen activator administration.
Results
From 2006-2010, 10,758 patients underwent mechanical thrombectomy for acute ischemic stroke (267 patients in 2006 and 4096 patients in 2010). A total of 631 patients underwent thrombectomy for posterior circulation strokes. Mortality rate among patients with posterior circulation occlusions was 40.5% (253/631). Morbidity rate was 33.6% (210/631). The rate of ICH for patients with posterior circulation occlusions was 15.7% (99/631). Mean length of stay was 11.9 ± 24.7 days. Mortality for patients <65 years old was 39.1% (155/398) compared to 43.0% (98/223) for patients ≥65 years old (P = 0.22). On multivariate analysis, posterior circulation occlusion (OR = 3.29, 95%CI = 2.71-3.98, P<.0001) and increasing age (OR = 2.10, 95%CI = 1.88-2.35, P<.0001) were significant predictors of increased mortality. Other significant predictors of increased mortality were male gender, white race, ICH and rt-PA administration.
Conclusion
Patients undergoing mechanical thrombectomy for posterior circulation occlusions suffered high morbidity and mortality rates. Posterior circulation occlusions are an independent risk factor for mortality amongst mechanical thrombectomy patients. More research is needed to improve outcomes among these patients and to determine which patients with posterior circulation occlusions will benefit from endovascular therapy.

Reduced Rates of Restenosis after Stent Angioplasty of Intracranial Atherosclerotic Stenoses with Drug Eluting Stents: Preliminary Experience with Taxus Element

Kurre, W.[1]·Aguilar-Pérez, M.[1]·Fischer, S.[1]·Arnold, G.[2]·Schmid, E.[3]·Bäzner, H.[3]·Henkes, H.[1]
[1]Katharinenhospital, Stuttgart, GERMANY, [2]Klinikum Sindelfingen-Böblingen, Sindelfingen, GERMANY, [3]Klinikum Stuttgart, Stuttgart, GERMANY.

Purpose
Stent angioplasty of intracranial atherosclerotic lesions is associated with high rates of restenosis. Small cases series with drug eluting stents (DES) showed promising results in terms of long-term stability but the high rigidity of DES was a major drawback. Modifications in stent design improved the flexibility of DES making them more suitable for the application in intracranial vessels. In this study we report our experience with the thin-strut paclitaxel eluting Taxus Element stent for the treatment of intracranial atherosclerotic lesions.
Materials & Methods
We retrospectively reviewed all patients having been treated with the Taxus Element DES in our institution for an intracranial atherosclerotic lesion. Patients treated in the setting of an acute vessel occlusion were excluded. Technical success was defined as the ability to place the Taxus Element at the desired location and reducing the degree of stenosis below 50%. To assess safety we reported procedure-related neurologic complications. Follow-up angiography was performed after six and 12 weeks, three and 12 months and yearly thereafter.
Results
Stent angioplasty with Taxus Element was attempted in 64 patients harboring 73 stenoses that were treated in 70 procedures. Nine of the target lesions were restenoses. The average degree of luminal narrowing was 73%. Thirty-four stenoses were located in the anterior, 39 in the posterior circulation. Seven lesions (9.6%) could not be accessed with Taxus Element and were treated by angioplasty alone or in combination with a self-expanding stent. The average degree of stenosis post-treatment was 21.5%. More than 50% luminal narrowing post-treatment

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

was observed in two (2.7%) cases. Neurologic complications associated with the treatment occurred in six (9.4%) patients of whom one (1.6%) had a permanent deficit. Control angiography was available for 52 of 64 (81.3%) successfully treated lesions after a median of 131 days. Angiographic imaging revealed one asymptomatic stent occlusion and one restenosis (3.8%). One patient developed a minor stroke due to discontinuation of clopidogrel after nine months and one patient had a stroke in the contralateral hemisphere.

Conclusion

Taxus Element reduced the rate of restenoses after stenting of intracranial atherosclerotic lesions below 4%. The new stent design improved the technical feasability of DES implantation now being comparable to bare metal balloon-expandable and self-expanding stents. Major complications are rare.

KEYWORDS: In-stent restenosis, Stenosis, intracranial stenting

Intraprocedural Cerebral Blood Volume Measurement Using C-Arm Computed Tomography for Acute Ischemic Stroke Management

Zhang, Y.[1]·Hong, B.[1]·Yang, Z.[1]·Liu, J.[1]·Ye, H.[2]
[1]Center of Clinical Neuroscience, Shanghai, CHINA, [2]Siemens China, Shanghai, CHINA.

Purpose

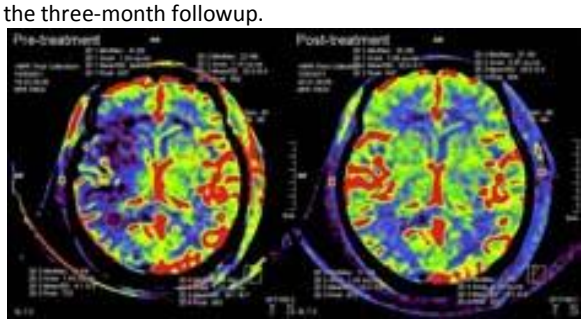
It is a challenge to make a clinical decision for an acute stroke patient with large intracranial artery occlusion. Brain perfusion images characterizing tissue viability are capable of providing a method to select patients who can benefit from endovascular treatment. This study is to investigate the value of intraprocedural cerebral blood volume (CBV) measurement using C-arm computed tomography (CA CT) in assessment of acute ischemic stroke and the effect of endovascular thrombolysis treatment.

Materials & Methods

Fifteen patients suffered from acute stroke were administrated in our hospital and were transferred to the cath lab for further diagnosis and treatment from August 2011 to October 2012. Nine out of fifteen patients diagnosed with digital subtract angiography (DSA) as big arteries occlusion in the anterior circulation were included in this study. Recanalization time from symptoms onset was from 115 min to eight hours. All these patients received endovascular thrombolysis therapy. Four patients accepted mechanical thrombectomy therapy, two received stenting treatment and three underwent both. C-arm CT was performed before and immediate after the treatment. Cerebral blood volume values were calculated with a commercial software (syngo DynaPBV Neuro, Siemens, Germany). Absolute CBV values of ipsilateral and contralateral areas, relative CBV values (rCBV = ipsilateral CBV/contralateral CBV) before and after treatment were statistically analyzed with paired t test.

Results

Vessel occlusions were in the middle cerebral artery (6/9), the internal carotid artery (ICA) (3/9). All patients underwent procedures uneventfully. There were obvious ischemic manifestations in CBV maps in eight patients. The mean ipsilateral CBV was 8.6 ± 3.5 ml/1000 ml, the mean contralateral CBV was 24.7 ± 7.4 ml/1000 ml before procedure ($P<0.01$). After endovascular thrombolysis, the ipsilateral and contralateral CBV values changed to 21.8 ± 8.8 and 24.0 ± 7.1 ($P = 0.19$), the rCBV increased dramatically from 0.32 to 0.96 ($P<0.01$). No symptomatic intracranial hemorrhage happened after procedures. mRS≤2 was observed in six patients three months later and no patient died and no major events occurred during the three-month followup.



Conclusion

Intraprocedural CBV measurement by CA CT showed the ipsilateral CBV significantly decreased during the onset of acute ischemic stroke, and recovered to nearly normal level after recanalization (Graph). It facilitates the diagnosis of acute stroke and the assessment of effect of procedure.

Imaging-to-Stent Deployment Time Interval Is Shorter during Daytime versus after Hours in Endovascular Therapy for Acute Ischemic Stroke

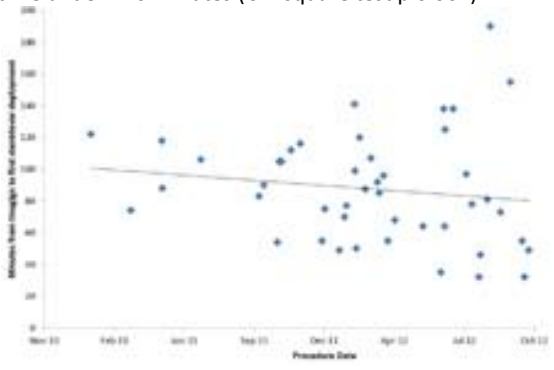
Almekhlafi, M. A.[1,2]·Eesa, M.[1]·Nambiar, V.[1]·Volny, O.[3]·Mishra, S.[1]·Desai, J.[1]·Zimmel, L.[1]·Menon, B.[1]·Demchuk, A.[1,4]·Goyal, M.[1,4]
[1]University of Calgary, Calgary, AB, CANADA, [2]King Abdulaziz University, Jeddah, SAUDI ARABIA, [3]St. Anne´s Faculty Hospital, Brno, CZECH REPUBLIC, [4]Hotchkiss Brain Institute, Calgary, AB, CANADA.

Purpose

The importance of time to recanalization in the management of acute ischemic stroke cannot be overemphasized. The stentretrievers introduced a unique advantage of establishing immediate flow to the ischemic tissue once the stent is deployed. A potential factor for delays in achieving a fast imaging to stentretriever

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

deployment time is the intervention timing. We assessed the feasibility of achieving a fast imaging to first stentretriever deployment during daytime hours.
Materials & Methods
This is a case series of acute ischemic stroke patients treated with endovascular therapy in a tertiary center. The imaging to first stentretriever deployment time was defined as the time from the completion of CT angiogram to the time of the first angiographic run showing the stentretriever deployment. This time interval was compared between patients treated during the daytime hours (0700-1800 hours) vs. outside these hours. CT perfusion, MR imaging was not used routinely. Endovascular procedures were done using local anesthesia.
Results
Ninety-nine patients with anterior circulation stroke were treated between January 2011 and October 2012. Of those, 62.9% were treated during daytime hours. The median imaging to first stentretriever deployment time was 86 minutes (80.5 minutes for daytime procedures vs. 97 minutes for procedures outside daytime hours; U-test p value 0.038). There was a trend towards shorter times likely due to streamlining of processes (Figure). The proportion of patients treated during daytime hours who achieved an imaging to first stentretriever deployment time under 120 minutes was 86% compared to 65.8% in procedures outside daytime hours (Chi-square test p 0.02). Outcome data were available for 50 patients (50%). The proportion of patients with a favorable discharge modified Rankin Scale (mRS <3) in the cohort that achieved an imaging to first stentretriever deployment time under 120 minutes was 65% compared to only 20% in the cohort who did not achieve that time interval (Chi-square test p 0.01). None of the patients who did not meet this target time achieved mRS score of one or less compared to 55% of those with an imaging to first stentretriever deployment time under 120 minutes (Chi-square test p 0.002).



Conclusion
An imaging to first endovascular stentretriever deployment time under 120 minutes is feasible. Focusing on streamlining workflow has the potential to reduce these times further. However it is affected by time of day and may be associated with better functional outcome.

Effective Patient Dose of Flat-Detector CT and Multislice CT Protocols: Comparative Measurements Using the Alderson Rando Phantom

Struffert, T.[1]·Hauer, M.[1]·Banckwitz, R.[2]·Koehler, C.[2]·Doerfler, A.[1]
[1]University Erlangen-Nuremberg, Erlangen, GERMANY, [2]Siemens AG, Healthcare Sector, Forchheim, GERMANY.

Purpose
Increasingly, flat detector CT (FD CT) is used for various applications in neuroradiology, such as brain visualization (DynaCT), intravenous FD CT angiography or petrous bone scanning, respectively. Additionally, intraarterial 3D DSA is used to supplement 2D angiographic studies. However, effective patient dose has not been sufficiently addressed in these new applications. The aim was to measure and compare the dose of 1) analogue FD CT and multislice CT (MS CT) protocols, and 2) standard 2D angiography protocols to intraarterial 3D DSA.
Materials & Methods
Using an Alderson Rando phantom effective patient dose (according to ICRP 103) was measured on a 128 row multislice CT (Siemens Somatom AS +) and a flat detector angiographic system (Siemens Axiom Artis dBA) using standard protocols as recommended by the manufacturer.
Results
1) Comparison of FD CT and MSCT (FD CT/MS CT): brain parenchyma imaging (Dyna CT) 2.9/1.4 mSv, perfusion imaging 2.3/4.2 mSv, petrous bone 0.4/0.2 mSv, angiography head 2.9 (using collimators 0.5)/0.5 mSv), respectively. 2) 2D angiography protocols: ap.-lat. standard series 1 mSv, enlarged oblique projection 0.3 mSv, intra-arterial 3D DSA 0.9 mSv (using collimators 0.3 mSv), respectively.
Conclusion
The effective dose of a brain DYNA CT is twice as high as for a MSCT, whereas other FD CT applications are in the dose range of MS CT. Using collimation for these FD CT applications, the dose may be reduced considerably up to 70%. Especially due to the low dose of 3D DSA, we recommend to use this technique primarily for visualization of aneurysms in order to reduce the number of 2D series to identify the ideal working position for endovascular therapy.

A Prospective, Multicenter Pilot Study for the Validation of Flat Panel Perfused Blood Volume Imaging in Patients with Cerebrovascular Disease

Fiorella, D. J.[1]·Turk, A.[2]·Woo, H.[1]·Deuerling-Zheng, Y.[3]·Sarmiento, M.[3]
[1]State University of New York at Stony Brook, Stony Brook, NY, [2]Medical University of South Carolina, Charleston, SC, [3]Siemens AG, Forchheim, GERMANY.

Purpose
Newer flat panel angiographic detector (FP) systems have the capability to generate perfused blood volume (PBV) maps. The ability to generate these maps in the angiographic suite has the potential to markedly expedite the treatment of patients with acute ischemic stroke. The present study compares FP PBV maps to cerebral blood volume (CBV) maps derived using standard dynamic computed tomographic perfusion (CTP) in a population of patients with cerebrovascular ischemic disease.
Materials & Methods
Fifty-two patients with cerebrovascular ischemic disease at two participating institutions prospectively underwent both standard dynamic CTP imaging followed by FP PBV imaging (syngo Neuro PBV IR; Siemens, Erlangen, Germany) under a protocol approved by both Institutional Review Boards (IRB). The feasibility of the FP system to generate PBV maps was assessed. The radiation doses for both studies were compared. The sensitivity and specificity of the PBV technique to detect (1) any blood volume deficit and (2) a blood volume deficit greater than one third of a vascular territory were defined using standard dynamic CTP CBV maps as the gold standard.
Results
Of 52 patients imaged, PBV maps were technically adequate in 38 (73.1%). The 14 inadequate studies were not interpretable secondary to patient motion/positioning (4), injection issue (2), or other (8). The average dose for FP PBV was 247 mGy (median 231) versus 208 (median 20) for CTP CBV. On CTP derived CBV maps 23 of 38 had a CBV deficit (60.5%) and 12 (31.6%) had a deficit that accounted for greater than one third of a vascular territory. FD PBV maps were 100% sensitive and 86.7% specific to detect any CBV deficit and 100% sensitive and 65.4% specific to detect any CBV deficit of greater than one-third of a territory.
Conclusion
Perfused blood volume maps can be generated using FP systems. The average radiation dose is similar to a standard CTP examination. Perfued blood volume maps have a high sensitivity for detecting CBV deficits defined by conventional CTP. Perfused blood volume maps tended to overestimate the size of CBV deficits. This overestimation most likely indicates that the FP protocol initiates parenchymal imaging prior to complete saturation of the blood volume in areas perfused via indirect pathways (i.e., leptomeningeal collaterals).

Thrombus Density Does Not Predict Angiographic Results of Mechanical Thrombectomy with Stentretrievers

Yilmaz, U.·Roth, C.·Reith, W.·Papanagiotou, P.
Saarland University Hospital
Homburg, GERMANY.

Purpose
Mechanical thrombectomy with stentretrievers in acute stroke has emerged as a promising new technique with the highest recanalization rate of the therapeutic procedures available so far. However, in up to 20% of the cases mechanical thrombectomy with stentretrievers results in poor angiographic outcomes with TICI-scores ≤ 2a. The purpose of this study was to investigate whether thrombus density on the initial CT scan can predict the angiographic outcome of the recanalization procedure in MCA occlusions.
Materials & Methods
The data of 70 patients with acute MCA-occlusions who underwent endovascular treatment with stentretrievers in our department were included. We analyzed thrombus densities, angiographic outcome and periprocedural thrombus fragmentation and embolization to a more distal position or branch.
Results
The mean thrombus density was 49.8 ± 7.8 HU and the mean difference to the density of the contralateral MCA was 9.9 ± 8.0 HU. There were no significant differences in the thrombus densities of occlusions that were successfully recanalized (mTICI ≥ 2b) and those that were not. Neither were there significant correlations of thrombus densities and periprocedural thrombus fragmentations and embolizations which occurred in 64.3% and 54.3% respectively. We found a nonsignificantly higher rate of recanalizations mTICI ≥ 2b when the difference to the density of the contralateral MCA was between 1 and 20 HU. This tendency increased in the group of patients who were treated by combined IV-rtPA and mechanical thrombectomy (86.2% versus 57.1%, P = 0.081) and disappeared in the group of patients who were treated by mechanical thrombectomy only (82.8% versus 80.0%, P = 0.881). Separately analyzing rates of thrombus fragmentation and embolization we found a nonsignificant increase in those rates in the cases with differences outside the range 1 to 20 HU who had been treated by combined IV-rtPA and mechanical thrombectomy.
Conclusion
In contrast to results of other revascularization procedures as published in a recent study, the angiographic result of mechanical thrombectomy with stentretrievers is not predicted by thrombus density. This might indicate that higher performance of stentretrievers is in part due to an insensibility of stentretrievers to different clot compositions. Yet when IV-rtPA and mechanical

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

thrombectomy are combined there are nonsignificant differences in the rates of successful recanalization, thrombus fragmentation and embolization. These results raise the question whether IV-rtPA might lead to higher rates of thrombus fragmentation and embolization during mechanical thrombectomy in some cases with certain thrombus compositions. This will have to be addressed in studies with larger case numbers.

Angiographic Collateral Score as a Predictor of Clinical Outcome and Contrast Staining in Acute Large Vessel Ischemic Stroke

Amans, M. R.·Cooke, D. L.·Vella, M.·Hetts, S. W.
University of California San Francisco
San Francisco, CA.

Purpose
Improvements in endovascular techniques for revascularization in patients with acute ischemic stroke (AIS), have led to improved reperfusion rates. Both the thrombolysis in cerebral infarction (TICI) score and the extent of pial collateral circulation have been shown to predict clinical outcomes. Contrast staining when defined as high density without mass effect on CT after endovascular intervention in AIS patients has been shown to be an early indicator of parenchymal infarction, and these cases rarely undergo hemorrhagic transformation. We sought to determine if change in pial collateral circulation before and after revascularization predicts adequate reperfusion in AIS patients.
Materials & Methods
Retrospective review was performed of imaging and charts of patients with anterior circulation AIS who underwent cerebral angiogram and had at least one subsequent CT. Diagnostic cerebral angiograms were reviewed independently by 3 ACGME fellowship-trained neuroradiologists who also have had additional subspecialty training in neurointerventional radiology. Follow-up imaging was evaluated for contrast staining of brain parenchyma as a surrogate marker for parenchymal injury and hemorrhagic transformation. Change in modified Rankin score (ΔmRS, defined as mRS at discharge minus mRS at admission) was the primary measure of clinical outcome. Contributions of final TICI score after endovascular intervention, pial collateral circulation score prior to intervention, and change in pial collateral circulation (CiPC, defined as preintervention collateral score minus post intervention collateral score) to patient and imaging outcomes relative to known predictors of patient outcomes in AIS therapies (age, gender, presentation mRS, occlusion level, procedure length, time from stroke onset to intervention, tobacco use, alcohol use, diabetes, previously known vascular disease, hemorrhagic transformation after intervention, prior TIA, prior stroke, antecedent anticoagulation) were determined by logistic regression.
Results
Median admission mRS was three (0, 4) (25%ile, 75%ile), median discharge mRS was four (3, 5), and median ΔmRS was one (-1, 4). Parenchymal contrast staining on follow-up CT was evident in 63.4% of patients (45/71). Logistic regression analysis revealed that CiPC scores [odds ratio (OR): 0.678, 0.661, and 0.752 for readers 1, 2, and 3, respectively) and TICI scores after intervention (OR: 1.251, 1.784, and 1.697 for readers 1, 2, and 3 respectively) are independent predictors of ΔmRS (p = 0.006, 0.009, and 0.134; p = 0.257, 0.011, 0.023, readers 1, 2, and 3 for CiPC; TICI, respectively), and CiPC scores (OR: 1.106, 1.591, and 1.848 for readers 1, 2, and 3, respectively) and TICI scores after intervention (OR: 1.281, 1.451, and 1.714 for readers 1, 2, and 3 respectively) to be independent predictors of contrast staining on follow-up imaging (p = 0.53, 0.017, 0.031; p = 0.28, 0.14, 0.05, readers 1, 2, and 3 for CiPC; TICI, respectively).
Conclusion
Final TICI score (direct measure of antegrade flow to a vascular territory) and CiPC (regression of collateral circulation presumably secondary to improved antegrade flow to viable brain tissue) are independent predictors of patient outcomes as measured by improved mRS and imaging outcomes as measured by contrast staining in our patient cohort.

Update on the Pragmatic Ischemic Stroke Thrombectomy Evaluation Randomized Controlled Trial

White, P. M.[1]·Muir, K.[2]·Ford, G.[1]·Brown, M.[3]·Clifton, A.[4]·Murray, A.[5]·Ford, I.[5]
[1]Institute for Ageing & Health, Newcastle upon Tyne, UNITED KINGDOM, [2]Institute of Neurosciences, Glasgow, UNITED KINGDOM, [3]University College London, London, UNITED KINGDOM, [4]St. Georges Hospital, London, UNITED KINGDOM, [5]Glasgow University, Glasgow, UNITED KINGDOM.

Purpose
To provide early recruitment data arising from the UK-based Pragmatic Ischemic Stroke Thrombectomy Evaluation (PISTE) pragmatic randomized controlled trial [of mechanical thrombectomy plus IV thrombolysis (IVT) versus IVT in acute ischemic stroke] and an update on the progress of the trial.
Materials & Methods
Pragmatic Ischemic Stroke Thrombectomy Evaluation is a PROBE design multicenter randomized controlled trial with concealed allocation. Primary outcome is 90-day clinical outcome based on dichotomized modified Rankin Score. Groups are matched using appropriate minimization criteria. Secondary endpoints include ordinal shift analysis

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

of Rankin, days at home by 90 days, procedural safety, SICH rate, recanalization rate (as adjudicated by an independent panel of reviewers blinded to allocation). Analysis of results is on an intention to treat basis. The funders (Stroke Association) and trial sponsor (Greater Glasgow Health Board on behalf of UK NHS) have no control over the running of the trial and no access to the trial data. Pragmatic Ischemic Stroke Thrombectomy Evaluation is actively recruiting.

Results

Information on early patient recruitment will be provided at the ASNR meeting as part of an update on trial progress.

Conclusion

Pragmatic Ischemic Stroke Thrombectomy Evaluation is the first RCT examining thrombectomy within the fairly homogenous UK NHS healthcare system and one of only two PROBE trials directly comparing the addition of thrombectomy to best medical therapy (IVT), which is the most relevant clinical question to answer.

KEYWORDS: Thrombectomy, Stroke, thrombolysis

eP-203

Multimodal Stroke Imaging Including Time-Resolved Whole Brain Perfusion Imaging within the Angio Suite: Preliminary Results of a Novel Flat-Detector CT Application

Struffert, T.[1]·Deuerling-Zheng, Y.[2]·Strother, C.[3]·Goelitz, P.[1]·Lang, S.[1]·Doerfler, A.[1]
[1]University Erlangen-Nuremberg, Erlangen, GERMANY,
[2]Siemens AG, Healthcare Sector, Forchheim, GERMANY,
[3]University of Wisconsin, Madison, WI.

Purpose

Flat-detector CT applications that are available during endovascular procedures are used in increasing numbers in the neurointerventional angio suite. Recently feasibility of multimodal flat-detector stroke imaging including time-resolved perfusion imaging could be demonstrated in the experimental setting. To demonstrate clinical feasibility we reviewed our first acquisitions in patients and compared to standard methods (MRI/CT).

Materials & Methods

Under an institutionally approved protocol the new FD CT application (10 consecutive bi-directional rotations) was used in six patients with acute stroke (M1 occlusion, 2 right, 4 left) following endovascular stroke treatment. Intravenous contrast medium injection was used. Using standard software brain parenchyma (FD CT) and vascular structures (FD CTA) were reconstructed. Using prototype software calculation of cerebral blood flow (CBF), blood volume (CBV), mean transit time (MTT and time to peak (TTP) maps was possible using a standard deconvolution-based algorithm for dynamic perfusion quantification. The images were reviewed in consensus reading by two experienced neuroradiologists and compared to MRI/CT images (MR/CT perfusion, MR/CT angiography), respectively.

Results

In all except in one case endovascular treatment resulted in complete recanalization (TICI 0 to TICI 3). Flat-detector CTA reconstructions confirmed recanalization of the M 1 segment in successfully treated patients and persistent occlusion in one case. In two cases subarachnoidal hemorrhage was visible on postinterventional FD CT, confirmed by follow-up CT. Evaluation of the MTT/TTP maps showed symmetric normalization after recanalization. In the successfully treated patients CBF normalized in two and was increased (hyperperfusion) in three cases, CBV normalized in three and increased in two cases, respectively. In the unsuccessful case CBF and CBV lesion showed an increase in volume.

Conclusion

Time-resolved whole brain perfusion imaging within the angio suite is feasible and demonstrated good correlation to standard perfusion methods and follow-up imaging. In addition, visualization of brain parenchyma and vascular structures is possible providing “multimodal stroke imaging” within the angio suite. Further evaluation is necessary.

Increased Incidence of Intraprocedural Vasospasm with Use of Distal Protection Device during Carotid Stenting

Nazarian, J. P.·Vidal, L. L. M.·Badve, C. A.·Sunshine, J. L.·Blackham, K. A.
University Hospitals Case Medical Center
Cleveland, OH.

Purpose

A major risk of carotid artery stenting is dislodging and distal embolization of atherosclerotic plaque material. Intravascular distal protection devices have been introduced into clinical practice in an effort to address this problem. Multiple attempts to firmly establish that these devices reduce neurologic complications have met with mixed results. Furthermore, there has been only limited investigation of the relationship between use of a distal protection device and intraprocedural vasospasm. We studied the characteristics of patients who underwent cervical carotid stenting with and without use of a distal protection device.

Materials & Methods

Following approval by the institutional review board, a retrospective chart review was performed on 143 patients (median age 65.5 years, range 40-91 years) who underwent carotid stenting at our institution between February 2003 and November 2012. Demographic and clinical data, including age, sex, comorbidities, percent carotid stenosis, intra and postprocedural complications, and in-hospital mortality were obtained from paper charts

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

and electronic medical records. Comorbidities examined included hypertension, diabetes mellitus, hyperlipidemia, coronary artery disease, prior stroke, and smoking history. Complications included intraprocedural vasospasm and stroke. Patients who underwent carotid stenting were divided into two groups: 66 patients in whom a distal protection device was placed (DPD group) and 77 in whom it was not (non-DPD group). Statistical analysis was performed using a z-test and unpaired two-tailed student's *t*-test to detect differences in complication rates, as well as demographic characteristics and patient comorbidities, between the two groups. Distal protection devices used included Cordis Angioguard® and Abbott Accunet®.

Results

Out of total 143 patients who underwent carotid stent placement, 66 had a distal protection device placed and 77 did not. There were four procedure-related strokes (6.1%) and no procedure-related deaths in the DPD group, with two strokes (2.6%) and no procedure-related deaths in the non-DPD group. These differences did not achieve statistical significant. Three patients in the non-DPD died during their hospital stay for reasons not related to their stenting procedure. No significant differences were found between the mean patient ages, gender proportions, or percent carotid stenoses of the two groups. Comparison of comorbidities between the two groups revealed an increased history of coronary artery disease in the non-DPD group which was statistically significant ($p = 0.004$). No other significant differences in rates of comorbid conditions were identified. Subgroup analysis performed on 31 patients in the nonprotection device group for whom electronic procedure notes were available revealed two incidences of notable intraprocedural vasospasm (6.45%), compared with 15/66 (22.7%) in the distal protection device group ($p = 0.02$).

Conclusion

Use of a distal protection device was associated with a statistically significant increase in the incidence of intraprocedural carotid vasospasm. No significant difference in procedure-related strokes or mortality rates was detected between the two groups. The ostensible benefit of the embolic protection device may be outweighed by the increased complexity of the procedure including longer procedural times, increased difficulty with exchange of catheters while maintaining embolic protection device position and direct vascular untoward effects such as vasospasm.

KEYWORDS: Carotid artery stenting, Vasospasm, distal protection device

Use of Stentretrievers in Acute Ischemic Stroke: Performance Evaluation in a Patient-Specific Vascular Replica with and without Using a Balloon-Guide Catheter

Chueh, J. Y.[1]·Kuhn, A. L.[1]·Puri, A. S.[1]·Wilson, S.[2]·Wakhloo, A. K.[1]·Gounis, M. J.[1]

[1]University of Massachusetts Medical School, Worcester, MA, [2]Concentric Medical, Mountain View, CA.

Purpose

Expedited revascularization through mechanical thrombectomy is the principle goal of treatment of ischemic stroke, and may provide good clinical outcomes. In order to progress toward this goal, the latest stentretrievers were evaluated and compared to the Merci Retriever to understand their effectiveness under different clinical situations. Our hypothesis is that the mechanical properties of the embolism and the proximal flow control during thrombectomy contribute to successful recanalization and the potential for distal clot fragmentation.

Materials & Methods

Mechanical thrombectomy was performed with the use of the Trevo, Solitaire FR, and Merci Retriever in our in vitro MCA occlusion model. The occlusion model included proximal and distal collateral pathways in an effort to mimic functional human anatomy. The efficacy and safety of these thrombectomy devices were evaluated with and without temporary proximal balloon occlusion in both soft and hard clot analogues. Characterization of microemboli in the effluent was conducted by using the Coulter Principle.

Results

Partial flow restoration was observed immediately after deployment of the stentrievers (70.5 ± 26.6 and 46.2 ± 23.0 ml/min in the soft and hard clot occlusions, respectively). Applying aspiration during clot retrieval resulted in flow reversal. This phenomenon was more significant when proximal temporary occlusion with the balloon was used (-83.1 ± 66.7 versus -32.3 ± 48.8 ml/min, $P<0.0001$). All the soft occlusions were cleared successfully by mechanical thrombectomy regardless of device type and presence of proximal flow control (average thrombectomy attempt: 1.1). In the Trevo, Solitaire and Merci hard clot groups, all the procedures which were performed through a balloon-guide catheter (BGC) achieved complete flow restoration, giving a recanalization rate of 100% (average thrombectomy attempt: 1.1). In one out of eight hard occlusions in which BGC was not used, the Solitaire system was not able to retain the clot within the device during retrieval, resulting in a partial flow restoration (74.1%). Partial clot removal also occurred in one Merci experiment; however, the small residual clot did not obstruct any flow. The Merci device was less efficient in hard clot removal as compared to the Trevo and Solitaire devices (mean thrombectomy attempt: 1.5 versus 1.1). The rate of distal clot fragments with size greater

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

than 1000 µm and between 200-1000 µm from the hard clot model was significantly reduced with the deployment of BGC ($p<0.05$). However, the BGC offered only slight reduction of clot fragmentation for soft clots. There was a significant increase in the number of particles having a diameter between 8-200 µm generated during thrombectomy using the soft clot model ($p<0.0001$) regardless of BGC assistance or device used as compared to that with the hard clot model. The average particle diameter in this range was less than 10 µm in all groups.
Conclusion
The amount of flow restoration can be quantified and the size and number of the distal emboli generated during the procedure can be characterized by using the in vitro model system of cerebrovascular occlusion. The risk of distal embolization is reduced with the use of temporary flow arrest with a BGC.

KEYWORDS: Stroke, Thrombectomy, embolization

Utility of Temporary Balloon Occlusion Testing in Predicting Outcomes after Permanent Parent Vessel Occlusion

Whisenant, J. T.·Derdeyn, C. P.·Cross, D. T.·Moran, C. J.
Mallinckrodt Institute of Radiology
St. Louis, MO.

Purpose
To review the utility of the temporary balloon occlusion (TBO) test as it pertains to prediction of patient outcomes following permanent parent vessel occlusion. Patients often undergo TBO testing as part of the diagnostic workup prior to permanent parent vessel sacrifice. We perform a three-part test that includes intraprocedural neurologic assessment, neuroangiographic evaluation of the adequacy of collateral flow, and 99m-Tc-Bicisate administration during temporary balloon occlusion. Pending the TBO test results, parent vessel occlusion may be performed; and this patient population is at risk for postparent vessel sacrifice ischemic complications, such as TIA, stroke, and death.
Materials & Methods
Data were reviewed retrospectively from all patients who underwent ICA TBO from March 2002 to December 2011. Patients then were subdivided into those that underwent permanent ICA occlusion and those that did not. Data from those that underwent permanent ICA occlusion were collected over the succeeding six months for the occurrence of three primary outcomes: transient ischemic attack (TIA), ischemic stroke (CVA), and death. In the subgroup of patients with a CVA following the parent vessel occlusion, additional data were collected in the following areas: 1) type of parent vessel sacrifice (open versus endovascular), 2) timing of symptom onset (procedural, early postop, late postop), and 3) type/location of infarct. Based on these factors, a mechanism of the event was postulated (thromboembolic versus hemodynamic).
Results
One hundred fifty ICA TBOs were performed between March 2002 and December 2011. Thirty-six went on to have permanent endovascular or surgical ICA occlusion. In the group that had parent vessel sacrifice, there were the following outcomes: five TIAs (13.9%), six CVAs (16.7%), and three deaths (7.3% - all due to underlying malignancy). Of the nine patients with ischemic complications (i.e., TIA or CVA) after the parent vessel sacrifice, eight had SPECT performed and all eight were normal or had "fixed" defects, seven had angiography performed and sic of the seven were interpreted as normal, and all nine had clinical neurologic assessment performed and all nine passed. Of the six patients with CVA, four are postulated to be hemodynamic in etiology, one is postulated to be thromboembolic in etiology, and one is of indeterminate etiology (hemodynamic or thromboembolic).

Timing and Type of Ischemic Stroke Following Parent Vessel Sacrifice

PATIENT	AGE	TBO ANGIO RESULT	SPECT RESULT	TBO NEURO EXAM	METHOD OF SACRIFICE	TIME ONSET OF CVA	MECHANISM OF CVA	SYMPTOMS OF CVA
1	78	Not done	Pass	Pass	Endovascular	Early post-op (hours/days)	Hemodynamic/embolic - single centrum semiovale by CT	Mild RUE weakness
2	44	Pass	Pass	Pass	Open Surgical	Early post-op (hours/days)	Hemodynamic	Mild weakness - complete resolution at later followup
3	51	Pass	Not done	Pass	Endovascular	Early post-op (hours/days)	Hemodynamic - Centrum Semiovale	L hemiplegia, R facial droop
4	64	Fail	Pass	Pass	Open Surgical	Late post-op (weeks/months)	Hemodynamic - Centrum Semiovale	LUE weakness 4 months post op
5	86	Pass	Pass	Pass	Endovascular	Late post-op (weeks/months)	Thromboembolic - stump	LUE/LLE weakness and L sided neglect
6	73	Not done	Pass	Pass	Endovascular	Early post-op (hours/days)	Hemodynamic	R hemiplegia, R facial weakness, aphasia

Conclusion
The rate of ischemic stroke following ICA sacrifice in patients who have "passed" TBO testing is higher than expected. The majority of ischemic strokes affected the deep white matter of the centrum semiovale and occurred in the early or late postop period supporting a hemodynamic etiology. The SPECT and angiographic testing appears to be more effective in assessing cortical flow than assessing flow to the deep white matter.

Endovascular Treatment of Tandem Vascular Occlusions in Acute Ischemic Stroke

Puri, A. S.[1]·Kuhn, A.[1]·Hou, S.[1]·Khan, M.[1]·Kwon, H.[2]·Gounis, M. J.[1]·Wakhloo, A. K.[1]
[1]University of Massachusetts Medical Center, Worcester, MA, [2]Chungnam National University Hospital, Daejeon, KOREA, REPUBLIC OF.

Purpose
Tandem vascular occlusions represent a treatment

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

challenge in acute ischemic stroke (AIS). Both revascularization of the proximal lesion followed by the treatment of the distal occlusion or vice versa, have shown advantages as well as disadvantages. However, the order in which the affected vessels should be treated to achieve rapid and permanent flow restoration has not been determined yet. Here we evaluate the safety and efficacy of our approach and clinical as well as angiographic results for different endovascular treatment combinations for tandem vascular occlusions.

Materials & Methods

All patients with AIS secondary to tandem lesions treated endovascularly were identified either at the University of Massachusetts Memorial Medical Center(n=18) or at the Chungnam National University Hospital(n=3) between June 2006 and November 2012 and their data were reviewed. We included patients who presented with extracranial internal carotid artery (ICA) occlusion and a concomittant occlusion of either the distal ICA 'T' occlusion, middle cerebral artey (MCA) or the anterior cerebral artery (ACA). We also included patient with occlusion of the proximal vertebral artery (VA) and a simultaneous occlusion of the basilar artery (BA). We collected the information of each patient's stroke risk factors, National Institute of Health Stroke Scores (NIHSS) and modified Rankin Scores (mRS) on admission and at discharge. Data also collected included: method of anesthesia during intervention, means of intracranial revascularization and use of cerebral protection devices. The final recanalization achieved was evaluated by using the Thrombolysis In Cerebral Infarction (TICI) score.

Results

A total of 21 patients were identified to have tandem vascular occlusions. The mean age was 50 years. Patient comorbidities included smoking (38.1%), hypertension (57.1%), dislipidemia (33.3%), diabetes (19%) and alcohol abuse (23.8%). Mean NIHSS and median mRS at admission was 17.9 and five respectively. In 76.2% of cases, the intervention was performed under general anesthesia. An ICA lesion with concommitant MCA occlusion was present in 90.5% of cases. Involvment of the VA with basilar BA occlusion was seen in 9.5%. In 81% of patients (n = 17) treatment of the proximal occlusion was initiated followed by the distal occlusion. Endovascular protection devices for the ICA occlusion were used in five cases. Six patients received IV tPA prior to the endovascular intervention. In 94.7% of cases ICA revascularization was achieved with stent placement. Intra-arterial lysis was used mostly to recanalize the MCA occlusion (84.2%); both BA occlusions were treated with endovascular thrombectomy. Thrombolysis In Cerebral Infarction 2B and 3 recanalization was achieved in 14 cases (66.7%). An mRS of ≤2 at discharge was achieved in 38.1%; mean patient NIHSS was 8.1. Four patients died.

Conclusion

Our results show that an aggressive recanalization of tandem lesions can be used safely with an excellent outcome in a subgroup of patients with AIS. This subgroup has a bad natural history with a high morbidity and mortality. We prefer the proximal occlusion using a stent followed by distal recanalization with either mechanical, pharmaceutical or combined thrombolysis. This approach has low periprocedural complications and can achieve excellent angiographic and clinical outcome.

eP-208

Simple and Easy Way Using Time-Intensity Curve of Perfusion-Weighted Images to Find Penumbra in Stroke Patients within Twelve Hours of Onset Due to the Carotid Artery Occlusion

Mori, T.･Iwata, T.･Miyazaki, Y.･Nakazaki, M.･Takahashi, Y.
Shonan Kamakura General Hospital
Kamakura, JAPAN.

Purpose

The aim of our retrospective study was to find indicators of time-intensity curve (TIC) of PWI indicating penumbra in stroke patients with acute carotid artery occlusion.

Materials & Methods

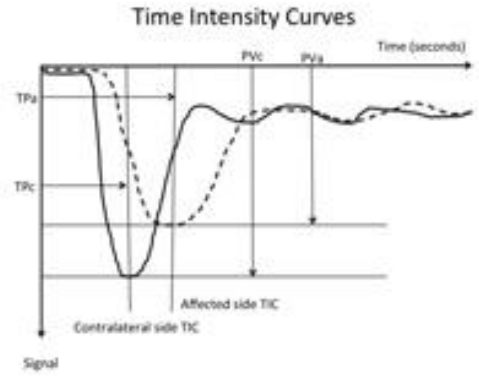
Included were acute stroke patients 1) who were admitted within 12 hours of onset between January 2005 and January 2012, and 2) in whom emergency MRA showed absolutely no visualization of the affected internal carotid artery (ICA). Patients who underwent intravenous tPA or endovascular treatment were excluded. We assessed, NIHSS on admission (NIH adm), NIHSS on the 7th day (NIH 7th), in-hospital death, the time to peak (TP) and the peak signal (PS) comparing the affected side (a) TIC with the contralateral side (c) TIC, which was generated on regions of interest set at symmetrical positions of the bilateral MCA territories. Time to peak delay was defined as TPa - TPc, PS% as PSa/PSc x 100. Early neurologic improvement (ENI) was defined as NIH adm - NIH 7th more than four or (NIH adm less than five and NIH 7th less than five). We evaluated relationship between TP delay, PS%, EMI and inhospital death.

Results

Fifty-nine patients were analyzed. Mean age was 78 years old. Thirty-one patients were women. Median NIH adm, NIH 7th, TP delay and PV% were 18, 24, 5.9 and 68.8, respectively. Twenty-two patients died during hospitalization. Thirteen patients had ENI. Time to peak delay ($p<0.01$) and PV% ($p<0.005$) were significant predictors of EMI. Receiver operating characteristics curves showed that cut-off points in TTP delay and PV% were 4.7 and 85, respectively. Time to peak delay ($p<0.05$) and PV% ($p<0.0005$) were significant predictors of inhospital death. Receiver operating characteristics curves showed that cut-off points in TP delay and PV% were 12 and 32, respectively. Among 40 patients without TP more than 4.7 and PV%less than 32, 11 patients had TP delay of 4.7 s and PS% of 32 or more and less than 85%, and only

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

one of them achieved ENI.



Conclusion
Time to peak delay more than 4.7 s and PS% of 32 or more and less than 85% were indicators of penumbra predicting neither early clinical improvement nor inhospital death.

One-Year Clinical Experience with the pREset 4/20 Stent Retriever for the Treatment of Acute Ischemic Stroke: A Review of 169 Consecutive Cases

Kurre, W.[1]·Aguilar-Pérez, M.[1]·Fischer, S.[1]·Schmid, E.[2]·Sperber, W.[3]·Bäzner, H.[2]·Henkes, H.[1]
[1]Katharinenhospital, Stuttgart, GERMANY, [2]Klinikum Stuttgart, Stuttgart, GERMANY, [3]Klinikum Esslingen, Esslingen, GERMANY.

Purpose
The purpose of this study was to evaluate the safety and efficacy of the pREset 4/20 stent retriever in a real world clinical setting.
Materials & Methods
We retrospectively analyzed all embolic cerebral vessel occlusions treated with pREset 4/20 between August 2011 and July 2012. Device-related complications, parenchymal hemorrhage type II (PHII) and diffuse SAH on follow-up imaging served as safety endpoints. In terms of efficacy, a TICI 2b and 3 score was regarded as successful recanalization and a mRS of 0-2 at 90 days was defined as good clinical outcome. In addition, we compared safety and efficacy between treatments performed with pREset alone and in combination with other devices.
Results
One hundred sixty-nine patients with 175 target vessels were included. Successful recanalization after the last pass with pREset was achieved in 78.9% of targets. The end of procedure successful recanalization rate was 91.4%. One vessel wall injury (0.8%) and 7.1% new emboli were related to pREset. PH II or diffuse SAH were observed in 8.9%. Good clinical outcome was achieved in 31.4%. Multiple devices were used in 29.7% of targets. Escalation of therapy was associated with an increased risk of vessel injury (p = 0.027) and a trend for lower recanalization rates, higher rates of hemorrhage on imaging and worse clinical outcome.
Conclusion
pREset 4/20 proved to be safe and effective with similar results compared to other stent retrievers. Escalation of therapy carries a higher procedural risk and should be performed only after a careful risk-benefit assessment.

Late Vertebro-Basilar Clot Retrieval: Angiographic and Clinical Outcomes

Djoukhadar, I. A.[1]·Alli, S.[2]·Hassan, A.[2]·Patankar, T.[1]·Goddard, A.[1]
[1]Leeds Radiology Academy, Leeds, UNITED KINGDOM, [2]Leeds Teaching Hospitals, Leeds, UNITED KINGDOM.

Purpose
To describe our experience in performing mechanical clot disruption and intra-arterial t-PA in patients presenting (>12 hours after ictus) with basilar thrombosis and rapidly deteriorating neurologic status.
Materials & Methods
Retrospective, single-center study of patients (N = 6, mean age of 44 years ranging from 10 to 78 years, 50% males) with basilar artery stroke with onset of symptoms at > 12 hours over two-year period (September 2010 - September 2012). Clot location, successful recanalization, device type, device-related complications, clinical outcomes (modified Rankin Scale score) and mortality at 90 days were assessed.
Results
Three patients had complete occlusion at the proximal basilar artery, two at the distal basilar artery (clot extension into right P1 and clot extension in both P1 segments) and one patient having left vertebral artery and proximal basilar artery thrombosis. The shortest time from symptom's onset to the angio-suite was 15 hours: 21 minutes and the longest was 74 hours: 33 minutes. None of our patients received intravenous t-PA bridging therapy. Devices used included five Solitaire stents (Three 6 x 30 and Two 4 x 20), three Revive Devices (4.5 x 22) and four Penumbra Devices (two 032, one 041 and one 054). The device-related complications included one case of stent collapse needing balloon angioplasty and a case of moderate vasospasm that was controlled with Nimodipine infusion. Complete recanalization (TICI 3) was achieved in three patients (50%) and partial recanalization (TICI 2B) but with good perfusion was achieved in the remaining three patients. The three-month outcome was favorable (mRS: 0 - 2) in three patients, poor (mRS: 4) in one patient and the mortality rate at three months was 33% (two

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

patients died).
Conclusion
Mechanical clot retrieval beyond 12 hours achieves good recanalization rates. Good clinical outcomes can be achieved in carefully selected patients.

Post-Thrombectomy Hemorrhage: Ischemia on CT Angiography as a Predictor of Hemorrhage Rates

Nickell, L. T.·Hise, J. H.·Layton, K. F.
Baylor University Medical Center
Dallas, TX.

Purpose
Intracranial hemorrhage is a feared complication of mechanical endovascular thrombectomy and intra-arterial thrombolysis and causes significant morbidity and mortality. The purpose of this study is to identify if post-thrombectomy/thrombolysis hemorrhage rates could be predicted based on the extent of cerebral ischemia identified on CT angiographic source images.
Materials & Methods
We conducted a chart review of all neurointerventional cases of stroke treatment by mechanical thrombectomy and/or intra-arterial thrombolytic administration. The degree of ischemia was measured on source images from CT angiograms obtained immediately before intervention. Successful recanalization rate and postoperative hematoma formation is measured. Only cases involving the anterior circulation were considered. Clinical and imaging data were analyzed retrospectively.
Results
A total of 157 cases of neurointerventional stroke treatment were identified. Thirty-one cases were eliminated (18 involved the posterior circulation, 10 had no CT angiogram images, and four were complicated by aneurysm coiling), leaving 125 cases included in the dataset. Patients with very little to no ischemia on CTA source images (n = 64) demonstrated a hematoma formation rate of 6.3% (n = 4). Cases with marked ischemic changes (n = 61) showed a parenchymal hematoma rate of 16.4% (n = 10).
Conclusion
Evaluation of the source images from CT angiography for ischemic change can be a valuable tool in identifying a patient's risk of post-thrombectomy hemorrhage, as the rate of postoperative hemorrhage increases significantly if marked ischemic changes are seen on pretreatment scans.

eP-212

Endovascular Management of Inoperative Meningiomas

Yakes, W. F.
Vascular Malformation Center
Englewood, CO.

Purpose
To determine the efficacy of ethanol embolization of single and multiple meningiomas in poor surgical candidates.
Materials & Methods
Eleven patients (eight female, three male; mean age 52 years) underwent clinical, MR, and angio evaluations. In patients who had postsurgical recurrence and/or were poor operative risks, ETOH embo was offered as an alternative procedure. Two patients had multiple meningiomas related to Von Recklinghausen's Neurofibromatosis Type II.
Results
All patients underwent ethanol embolization of single and multiple pedicles supplying the tumor. Four patients suffered complications (one patient minor late SAH without sequelae, two patients transient 6^{th} nerve palsy, one patient transient worsening of aphasia). MR imaging and CT demonstrated significant necrosis and shrinkage of the tumors at long-term followup (range: 6-72 mos; mean: 30 mos).
Conclusion
ETOH, being a liquid agent, penetrates to the capillary level causing necrosis and exclusion of collateral flow. This leads to tumor necrosis and shrinkage. Taking advantage of the slow-growing, non-metastasizing characteristics and increased vascularity of this tumor, ETOH is an attractive alternative therapy that is minimally invasive. This treatment can be offered in selected poor surgical patients. This procedure is efficacious in highly vascular tumors and in poorly vascularized meningiomas not possible to treat surgically.

Mandibular Arteriovenous Malformation Diagnosis and Curative Treatment

Yakes, W. F.
Vascular Malformation Center
Englewood, CO.

Purpose
To determine optimal management strategies for the treatment of mandibular arteriovenous malformation (AVM).
Materials & Methods
Twelve patients (nine females, three males) age 9-14 years; mean age 10 years, underwent endovascular therapy to treat their mandibular AVMs. Nine patients had distinct intraosseous AVMs. Three had multiple facial and

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

intramaxillary AVMs requiring treatment. Outside institutions recommended massive hemifacila resections in these patients. Four patients had prior PVA and gel foam embolization, one patient had a lip graft, one had prior mandible surgery, all that had failed.

Results

All twelve patients have demonstrated MR and angiographic cure of their AVMs. One patient's therapy is not completed and is on-going. The followup is 1 month - 41 months, with a mean followup of 29 months. No complications were noted.

Conclusion

Endovascular approaches to manage mandibular AVM can be curative. The intraosseous variety is largely a fistula between artery and vein within the bone. All responded well to endovascular ethanol therapy alone. Surgery was not required in any patient. Surprisingly no complications were encountered in this patient series. Long-term cures are noted in this patient series with endovascular approaches alone. No massive surgical resections in any patient, even in patients with multiple AVMs of the soft tissues, mandible and maxilla, were required to effect cure.

Apparent Diffusion Coefficient Histogram Analysis of the Normal-Appearing Brain in Sickle Cell Disease

Watanabe, M.·Buch, K.·Jara, H.·Sakai, O.
Boston Medical Center
Boston, MA.

Purpose

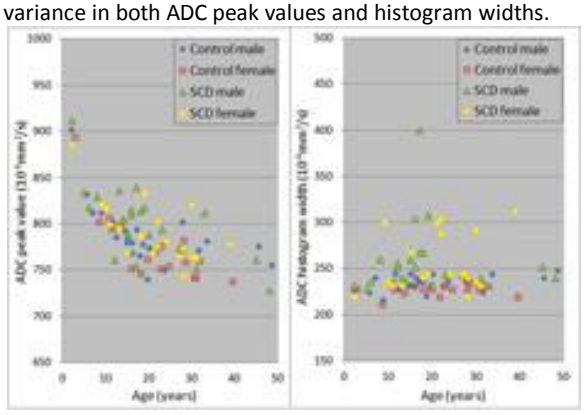
The purpose of this study is to investigate changes in apparent diffusion coefficient (ADC) histogram of the normal-appearing brain in patients with sickle cell disease (SCD), comparing with control population.

Materials & Methods

After acquiring IRB approval, this retrospective study included 41 SCD patients and 41 age-matched patient controls who underwent brain MR imaging for various clinical reasons during 2005-2008. All subjects showed no apparent abnormalities on conventional brain imaging. Both the SCD group and control group consisted of 22 males and 19 females (age range 2-48 years, average 20 years). All subjects were imaged at 1.5T (Achieva or Intera, Philips Medical Systems, Cleveland, OH) with our institutional clinical protocol that includes a single-shot diffusion-weighted echo-planar imaging pulse sequence (Key imaging parameters: 3899/74ms TR/TE, 89 EPI-factor and b = 0, 1000 smm^{-2}). Diffusion-weighted imaging data were DICOM transferred for processing, and the whole intracranial volume including the cerebrospinal fluid, gray and white matters, was segmented using a single-channel dual-clustering algorithm. Apparent diffusion coefficient histogram of the whole intracranial volume was generated and further modeled with Gaussian functions. Apparent diffusion coefficient peak values and histogram widths were derived from these histograms, and plotted as a function of age. The paired t-test was used to analyze the difference between the SCD subjects and the age-matched controls.

Results

The histogram widths were significantly wider in the SCD group for both males (p<0.01) and females (p<0.01). The peak values of the ADC histograms were elevated significantly in female SCD subjects (p<0.01), while there was no statistically significant difference in ADC peak values between male SCD subjects and controls (p = 0.06). The SCD group demonstrated increased inter-subject variance in both ADC peak values and histogram widths.



Conclusion

The ADC histogram analysis revealed its potentials to visualize subtle changes in normal-appearing brains in SCD patients, demonstrating wider histogram distribution and increased ADC peak values.

Covert Hepatic Encephalopathy in Children with Liver Cirrhosis: Diffusion-Weighted MR Imaging and Proton MR Spectroscopy

Abdel Razek, A.·Ezzat, A.·Abdalla, A.·Megahed, A.
Mansoura University Hospital
Mansoura, EGYPT.

Purpose
To detect covert hepatic encephalopathy (CHE) in children with liver cirrhosis with diffusion-weighted MR imaging (DWI) and proton magnetic resonance spectroscopy (1H-MRS) of the brain.
Materials & Methods
Prospective study was conducted upon 30 consecutive children (age range 6-16 years, 21 boys and 9 girls) with liver cirrhosis and 15 age- and sex-matched healthy control children. Patients with CHE (n = 17) and with no CHE (n = 13) groups and control group underwent DWI, 1H-MRS, neuropsychologic tests (NPT) and electroencephalogram (EEG). The ADC values and integrals of glutamate or glutamine (Glx), myoinositol (mI), choline (Cho) and creatine (Cr) at the right ganglionic region were calculated. Metabolic ratio of Glx/Cr, mI/Cr, and Cho/Cr were calculated.
Results
There was significant difference between CHE, no CHE and control group in the ADC value (P = 0.001 for all groups), GLx/Cr (P = 0.001 for all groups), mI/Cr (P = 0.004, 0.001, 0.001 respectively), Ch/Cr (P = 0.001 for all groups), full scale IQ of NPT (P = 0.001, 0.001, 0.143 respectively) and EEG background frequency (P = 0.001, 0.001, 0.063 respectively). The NPT had negative correlation with ADC value (r = -0.872, P = 0.001) and GLx/Cr (r = -0.812, P = 0.001) and positive correlation with mI/Cr (r = 0.732, P = 0.001). The EEG background frequency had negative correlation with ADC value (r = -0.957, P = 0.001) and GLx/Cr (r = -0.855, P = 0.001) and positive correlation with mI/Cr (r = 0.775, P = 0.001).
Conclusion
We concluded that DWI and 1H-MRS are noninvasive imaging modalities that can be used to detect CHE in children with liver cirrhosis and correlated well with parameters of NPT and EEG.

Longitudinal MR Studies in a Patient with Medium-Chain Acyl-Coenzyme-A-Dehydrogenase Deficiency

Bernardi, B.·Figà-Talamanca, L.·Longo, D.·Verdolotti, T.
Bambino Gesù Pediatric Hospital
Rome, ITALY.

Purpose
We report serial brain MRI and H-MR spectroscopy (MRS) changes in patient with medium-chain acyl-coenzyme-A-dehydrogenase (MCAD) deficiency who developed acute encephalopathy. MCAD is an enzyme of the mitochondrial b-oxidation of fatty acids, an essential source of energy for cells during stress. Usually the first clinical presentation occurs by age of two with onset of acute hypoketotic hypoglycemia. Clinical features of this decompensated state include seizures and lethargy progressing to death if not treated prompty with dextrose infusion. Diagnosis is suspected on the basis of plasma acylcarnitine levels and altered urinary organic acid profile and confirmed through genetic analysis or demonstrating reduced enzyme activity. To the best of our knowledge, there are only a few reports describing brain MRI findings in MCAD deficiency and no systematic description of neuroimaging features has been reported.
Materials & Methods
A 12-month-old girl presented with sudden onset of acute encephalopathy. Baseline laboratory investigations revealed severe hypoglycemia, hyperammonemia and hyperchloremic metabolic acidosis. Patient was treated with glucose infusion that resulted in a progressive normalization of glucose and ammonia blood levels and gradual resolution of symptoms. The first conventional MR imaging, performed within six hours of onset, was normal, while there were bilateral symmetric restricted diffusion lesions on diffusion-weighted imaging (DWI) in the middle cerebellar peduncle, nucleus caudatus, putamen and periventricular white matter. To confirm visual assessment of DWI, a quantitative measurement of apparent diffusion coefficient (ADC) was calculated in eight different anatomical locations for each hemisphere. Resulting ADC values were significantly lower than those measured in five age-matched healthy subjects. Second MRI, 24 hours after onset, did not show conventional MRI or DWI abnormalities. Quantitative assessment of ADC confirmed the complete resolution of previously reported DWI abnormalities. The third MRI, at 72 hours, revealed bilateral symmetric hyperintensity on T2-weighted imaging in the middle cerebellar peduncle, nucleus caudatus, putamen and periventricular white matter. DWI showed low ADC values in both globus pallidus. Single-voxel H-MRS revealed higher than normal GABA and glutamine in nucleus lenticularis. Four weeks after first neuroimaging, MRI revealed widespread atrophy and high T2 in both globus pallidus. DWI did not reveal any notable signal abnormality and ADC was normal. Single-voxel MRS showed normalization of GABA and glutamine.
Results
MCAD usually appears acutely and has high morbidity-mortality rates; early diagnosis is therefore important to promptly begin treatment. Furthermore genetic counseling may provide useful information to prevent triggering events and assess genetic risk to siblings.
Conclusion
In our opinion the case described has several interesting aspects: - It demonstrates the role of MRI in early diagnosis of the decompensated state of the disease; in

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

our case DWI revealed bilateral symmetric distribution of lesions that strongly suggested a metabolic disease. - Ours and other recent studies demonstrate that acute hypoglycemia may cause bilateral lesions not only in gray matter areas that are known to be more susceptible to injury, but also in white matter locations. - Severe hypoglycemia may cause reversible restricted diffusion that could be pathogenetically different from the irreversible cell necrosis observed in ischemia.

Proton MR Spectroscopy of the Brain in Children with Neuronopathic Gaucher Disease

Abdel Razek, A.·Abdalla, A.·Abdel Gaber, N.·Megahed, A.·Fathy, A.·Barakat, T.
Mansoura University Hospital
Mansoura, EGYPT.

Purpose
To assess the clinical usefulness of proton MR spectroscopy (1H-MRS) in children with neuronopathic Gaucher disease (NGD).
Materials & Methods
Prospective study was conducted upon 21 consecutive children with acute (n = 6) and chronic (n = 15) forms of NGD (14 boys, seven girls age range from 7 months to 72 months: mean 45 months) and for age- and sex-matched control group (n = 15). All patients and controls underwent single voxel 1H-MRS of the frontal white matter using short and intermediate TE (30 and 135 ms). The integrals of choline (Ch), creatine (Cr), myoinsoitol (mI) and lipid were assigned. The mI/Cr, Ch/Cr were calculated. The modified severity scoring tool (m-SST) of NGD was calculated and genotyping was performed for all patients. The metabolites correlated with clinical types, m-SST and genotyping.
Results
There was significant difference in Ch/Cr (P = 0.001) and mI/Cr (P = 0.001) between patients with NGD and control group. Lipid peak was detected in 14 patients with NGD. Patients with acute NGD revealed higher m-SST (P = 0.001), Ch/Cr (P = 0.001) and mI/Cr (P = 0.001) compared to the chronic form. Patients with homozygous gene mutation (L444P/L444P) mutation had significantly higher m-SST (P = 0.001), Ch/Cr (P = 0.001) and mI/Cr (P = 0.001) than those with heterozygous gene mutation (L444p/D409H). The Ch/Cr ratio was well correlated with m-SST (r = -0.727; P = 0.001) and genotying (r = -0.727; P = 0.001).
Conclusion
We concluded that 1H-MRS may be used to detect brain abnormalities in children with NGD and Ch/Cr and mI/Cr are well correlated with m-SST and genotyping.

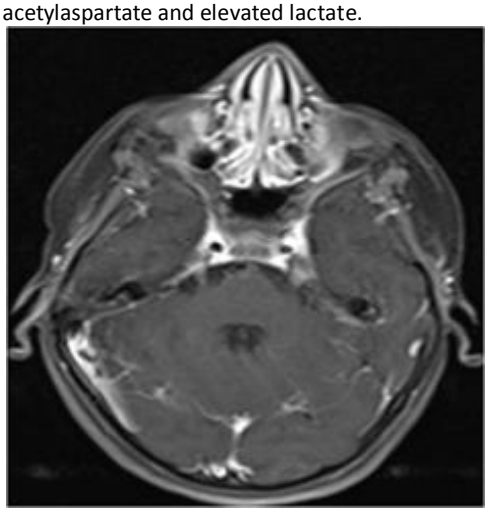
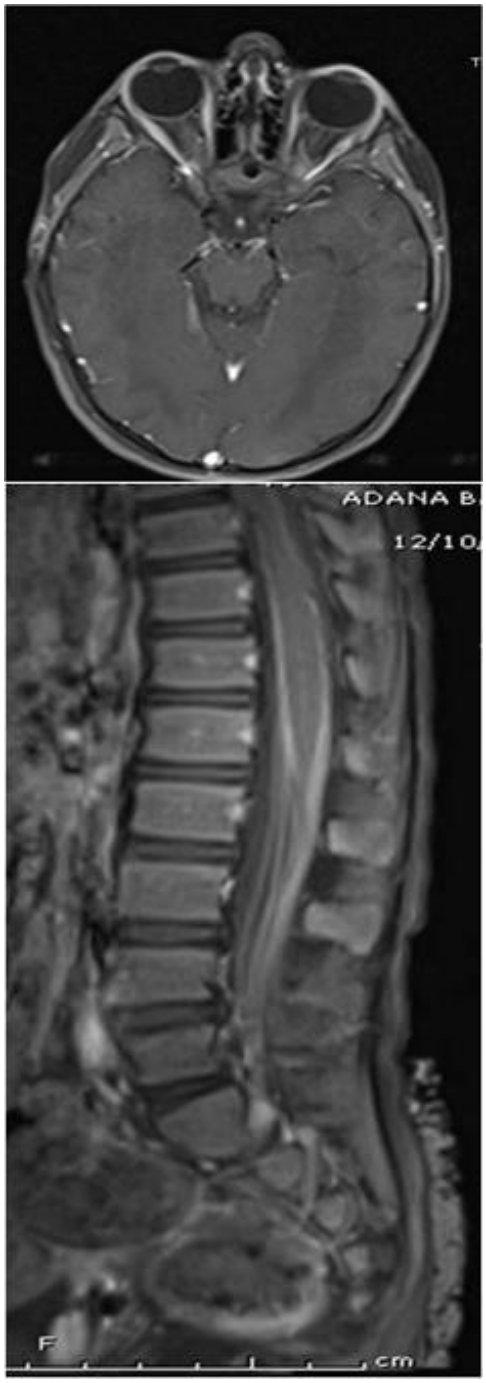
Role of Contrast-Enhanced Brain and Spinal MR Imaging in Metachromatic Leukodystrophy

Alkan, O.·Saygi, S.·Pekoz, B.·Altinkaya, N.·Demir, S.
Baskent University
Adana, TURKEY.

Purpose
To present contrast-enhanced brain and spinal MR imaging findings a patient with metachromatic leukodystrophy (MLD).
Materials & Methods
Five-year-old female child presented with walking and speech disorders. The patient underwent contrast-enhanced brain MR, diffusion MR, MR spectroscopy and contrast-enhanced lumbar spine MR imaging.
Results
T2-weighted image of the brain showed abnormal hyperintensity in the deep and periventricular white matter and posterior limbs of the internal capsules. Diffusion-weighted imaging showed decreased water diffusivity in affected regions. Postcontrast T1-weighted image of the brain showed enhancement of the cranial nerves (Figure 1a, b). Postcontrast T1-weighted image of the lumbar spine displayed enhancement of the cauda equina (Figure 2). MR spectroscopy showed decreased N-acetylaspartate and elevated lactate.



Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Conclusion
Metachromatic leukodystrophy is one of the more common leukodystrophies with well documented white matter findings. However, involvement of the cranial nerves and cauda equina on MR images are being reported only recently. The contrast enhancement of cranial nerves and cauda equina may accompany the white matter findings of MLD. Contrast-enhanced brain and spinal MR imaging may prove useful in diagnosing or differentiating the various leukodystrophies.

KEYWORDS: Contrast-enhanced MR imaging, Spinal imaging, metachromatic leukodystrophy

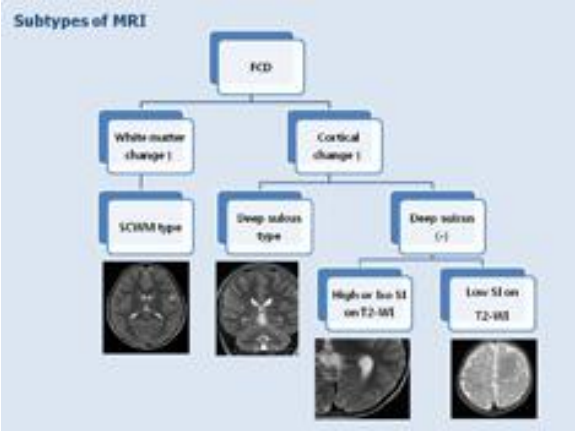
Focal Cortical Dysplasia in Children and Adolescents: MR Features and Related Clinical Outcomes

Cheon, J.·Choi, Y.·Kim, I.·Kim, W.
Seoul National University
Seoul, KOREA, REPUBLIC OF.

Purpose
To analyze MRI features of children and young adolescents with focal cortical dysplasia (FCD) in order to identify predictive factors for clinical outcomes.
Materials & Methods
From January 2005 to March 2012, 372 children and young adolescents with partial or secondary generalized seizure had MRI performed using 1.5T or 3.0T MR equipment in our hospital. Among them, 76 patients with one identified area of seizure onset zone on MRI which correlated with clinical history, seizure semiology, EEG abnormalities or other imaging modalities were included in our study. Other patients with negative MRI findings, multiple epileptogenic lesions or other epileptogenic lesions such as tumor were excluded from our study. We evaluated cortical and subcortical signal abnormalities on T2-weighted image (T2WI), blurring of gray-white matter junction, thickening of the cortex, abnormal deep sulci or transmantle sign. More than 2 years free of seizures was defined as a good prognosis. We compared clinical features, seizure history and MR features between refractory group and two-year seizure-free group.
Results
Twenty-four patients had more than 2 years free of seizures suggesting good prognosis while 52 patients had refractory seizure. MR findings were subcategorized into four groups: predominantly involved subcortical white matter with hyperintensity on T2WI (n = 23), localized cortical thickening with deep sulci (n = 21), diffuse cortical abnormality with hyper or isointensity on T2WI (n = 24), diffuse cortical abnormality with hypointensity on T2WI (n = 8). Patients with both cortex and white matter abnormalities (p = 0.028), hypointensity of the involved cortex (p = 0.01), and hyperintense subcortical WM abnormalities (p = 0.028) showed poor clinical outcome.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Conclusion
This study suggests that hypointensity on involved cortex on T2WI or concurrence of cortical and white matter abnormalities may be related to poor clinical features in patients with FCD.

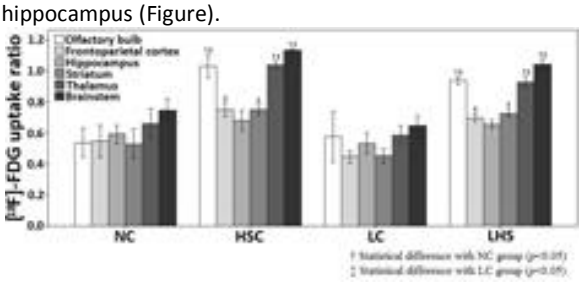
Ictal Hippocampal Metabolism in Experimental Prolonged Febrile Seizures

Clerk-Lamalice, O.[1]·Carmant, L.[2]·Lepage, M.[3]·Lecomte, R.[3]
[1]University of Sherbrooke, Sherbrooke, QC, CANADA, [2]Sainte-Justine Research Center - University of Montreal, Montreal, QC, CANADA, [3]Sherbrooke Molecular Imaging Center - University of Sherbrooke, Sherbrooke, QC, CANADA.

Purpose
Febrile seizures (FS) are the most common type of benign convulsions observed in young children. On the other hand, retrospective studies have demonstrated that candidates to temporal lobe epilepsy (TLE) surgery had higher prevalence of FS in childhood. Also, many patients with TLE and mesial temporal sclerosis have cortical dysplasia (CD). However, the link between CD, atypical FS and TLE remains unclear. Studies from our group demonstrated long-term hippocampal injury in animals with experimental CD and FS. In this study, we investigate ictal epileptic activity assessed by [18F]-FDG PET in a FS experimental rat model.
Materials & Methods
Ten male Sprague-Dawley rat pups were divided into four groups: naïve controls(NC, n=2), hyperthermic seizures controls (HSC, n=2), freeze-lesion controls (LC, n=2) and freeze-lesion pups with hyperthermic seizure(LHS, n=4). A freeze lesion was induced on the right frontoparietal cortex to mimic CD at postnatal day one (P1). At P10, [18F]-FDG was injected intraperitoneally(26.5±5.0 MBq). Animals then were placed in a box heated with warm dry air and removed after three minutes of generalized seizure. PET images then were acquired under anesthesia with a LabPET4 small animal scanner for a period of 60 minutes. Manual delimitation of the hippocampus, olfactory bulb, frontoparietal cortex, striatum, thalamus, brainstem and cervical spinal cord was performed with the help of an atlas using inhouse software. [18F]-FDG uptake ratios in each brain structure were calculated relative to the spinal cord uptake values. Statistical analysis between groups for each structure was performed with ANOVA Tukey posthoc test with p=0.05.
Results
Ictal [18F]-FDG uptake increased statistically between groups for all structures studied except in the hippocampus (Figure).



Conclusion
Interestingly, the absence of [18F]-FDG increase uptake in the seizing hippocampus is paradoxical. It has been demonstrated that hyperthermia-induced seizures have their onset and persist in limbic structures. Thus an increase uptake in this region was expected. Low brain protein expression of GLUT1 and GLUT3 and a failure of perfusion adaptation in the hippocampus secondary to inhomogeneous vascular bed may be the cause of an hypoxic-metabolic mismatch. CD did not play a role in this study probably because of the fixed length of generalized seizures for LHS and HSC groups. With nonsustained seizures, previous results showed that LHS rats have longer and more severe convulsions. These convulsions could be prone to hypoxic-metabolic mismatch and explain subsequent hippocampal atrophy, cognitive deficits as well as spontaneous recurrent seizures seen in LHS rats only.

Feasibility of Neonatal Thalamic Parcellation Based on Probabilistic Neocortical Connections

de Macedo Rodrigues, K.[1]·Ben-Avi, E.[2]·Choe, M.[1]·Drottar, M.[1]·Grant, P.[1]·Zöllei, L.[2]
[1]Children's Hospital Boston, Boston, MA, [2]A.A. Martinos Center for Biomedical Imaging/Massachusetts General Hospital, Boston, MA.

Purpose
The thalamus has a crucial role in integrating motor and somatosensory systems and special attention has been

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

given to its significance in cognition. Comprehension of the normal thalamic structural and functional development could have a significant impact on our understanding of the thalamic physiology, how it is related to different brain areas. It also would be important as a reference when studying how the thalamus and its connections are affected in pathologic states. The purpose of this preliminary study is to provide a parcellation of the thalamus in clusters derived from thalamic connections to predefined neocortical targets determined by probabilistic diffusion tractography in a neonatal population. We anticipate that these clusters will retain an anatomical and functional correspondence to known thalamic nuclei. This approach has been demonstrated successfully previously for the adult population.

Materials & Methods

We selected magnetic resonance imaging (MRI) scans from five term neonates, whose study included three-dimensional multiecho magnetization-prepared rapid gradient-echo imaging with motion correction and diffusion tensor imaging (DTI) with 30 noncollinear directions and 5 low b-values. All scans were acquired in a 3T system with a 32-channel adult head coil. All the studies were interpreted as normal by a pediatric neuroradiologist. Tools from the FSL library were used to run probabilistic diffusion tractography. The thalamus was defined as seed region and pre-established neocortical areas were target regions. These comprised of the prefrontal cortex, premotor and primary motor areas, the somatosensory area, the posterior parietal cortex, as well as the occipital and temporal lobes. The seed and target areas were segmented manually using Freeview (http://surfer.nmr.mgh.harvard.edu/FreeviewGuide).

Results

We were able to regularly identify five main clusters for the thalamus, with the exception of the left thalamus in one subject, where four clusters were recognized. The identified clusters appear to bear anatomical and functional correspondence to the thalamic nuclei groups mediodorsal, ventral anterior and lateral, ventral posterior, pulvinar and geniculate bodies.

Conclusion

Our preliminary results suggest that parcellation of the neonatal thalamus based on neocortical connections obtained from probabilistic tractography is viable. We plan to expand the number of subjects studied, age range of subjects and compare normal development to pathologic states.

KEYWORDS: Thalamic, Probabilistic, parcellation

Diffusion Tensor Imaging in Pediatric Hypertrophic Olivary Degeneration

Meoded, A.·Poretti, A.·Jallo, G.·Burger, P. C.·Huisman, T. A. G. M.·Izbudak, I.
Johns Hopkins Hospital
Baltimore, MD.

Purpose

The Guillain-Mollaret triangle (GMT) or dentato-rubro-olivary pathway is a functional brain stem neurologic circuit. The triangle consists of 1) olivary-dentato fibers from the hilum of one inferior olivary nucleus (ION) crossing the midline and traversing the inferior cerebellar peduncle (ICP) of the contralateral side to reach the contralateral dentate nucleus, 2) dentato-rubral fibers arising from the contralateral dentate nucleus, entering their own superior cerebellar peduncle (SCP) and decussating within the midbrain to reach the opposite red nucleus and 3) the ipsilateral central tegmental tract (CTT) or rubro-olivary tract descending from the red nucleus to the original ION. Disruptive lesions affecting components of the GMT may result in hypertrophic olivary degeneration (HOD). We present diffusion tensor imaging (DTI) findings in a six-year-old girl with HOD. To our knowledge, this is the first dedicated DTI analysis of the GMT in a child with HOD.

Materials & Methods

A six-year-old girl presented with a subtle intention tremor of the left hand three months after neurosurgical resection of a midbrain pilocytic astrocytoma. Brain MRI was performed three months after neurosurgery on a 1.5T scanner. Diffusion tensor imaging data were acquired with a single-shot, spin-echo, echo-planar (EPI) sequence. Balanced pairs of diffusion gradients were applied along 21 directions using *b*-values of 0 s/mm^2 and 1000 s/mm^2. Diffusion tensor imaging postprocessing was performed off-line using MRI Studio software. Regions of interest (ROIs) were manually positioned bilaterally within the ION, ICP, dentate nucleus, SCP, and red nucleus. For every ROI, calculated fractional anisotropy (FA), mean diffusivity (MD), axial (AD) and radial (RD) diffusivity values were collected. For the purpose of statistical analysis, the same DTI postprocessing was performed for three age/gender-matched children with normal neurologic exam and normal brain MRI.

Results

In our patient, conventional MRI demonstrated a T2-hyperintense signal in both IONs (more pronounced on the right side) and the right ION was slightly enlarged suggesting bilateral HOD. Follow-up MRI five months later, revealed increased T2-hyperintensity of both IONs and enlargement of the right ION. Diffusion tensor imaging analysis revealed higher FA and AD values of the ION and lower FA, but higher RD values of all other GMT components compared to age- and gender-matched controls.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Conclusion
Diffusion tensor imaging analysis of the various components of GMT in pediatric HOD correlates with histopathologic findings. Increased FA values of the ION may be explained by increased packing of white matter fibers. However, associated hyperintense T2 signal is contradictory and the association between increased FA values and hyperintense T2 signal remains unclear. Low FA and high RD values of the other GMT components likely reflect additional demyelination associated with axonal degeneration. Selective evaluation of AD and RD may help to differentiate between the various components of myelin and axonal degeneration in HOD.

KEYWORDS: DTI, Pediatric brain, brain stem

Role of Screening Sinus CT in Pediatric Hematopoetic Stem Cell Transplant Patients

Oppenheimer, A. G.[1]·Dave, H.[2]·Symons, H.[3]·Huisman, T. A. G. M.[3]·Izbudak, I.[3]
[1]Cleveland Clinic Florida, Weston, FL, [2]Children's National Medical Center, Washington, DC, [3]Johns Hopkins Hospital, Baltimore, MD.

Purpose
Purpose of this investigation is to evaluate the role of screening sinus CT prior to hematopoetic stem cell transplantation(HSCT) as a predictor of developing post-HSCT sinusitis and as a baseline examination from which to compare post-HSCT scans. Furthermore, we correlate CT findings with the presence of acute clinical sinusitis in this unique immunocompromised pediatric population.
Materials & Methods
Medical records and CT scans of 100 consecutive pediatric patients who received a screening sinus CT prior to HSCT at Johns Hopkins Hospital from 2006-2010 were reviewed. Seventy of these patients had a sinus CT following transplantation. Pre- and post-HSCT sinus disease was evaluated using two methods:a quantitative scoring system established by Lund and Mackay(LM) and the "common-practice" radiology reporting of sinusitis based on the presence of air fluid levels, frothy secretions or total opacification of any individual sinus.
Results
Overall, nine patients had clinical sinusitis pre-HSCT while 18 patients developed sinusitis post-HSCT. Fourteen percent of patients with normal screening sinus CT subsequently developed clinical sinusitis post-HSCT compared with 23% of asymptomatic patients with radiographic abnormalities alone and 22% of patients with clinical sinusitis(Table1). This higher rate of developing post-HSCT sinusitis was not statistically significant(p=0.20). Furthermore, subgroup analysis of patients with abnormal scans stratified by LM score(mild/moderate/severe) or the presence of particular "common-practice" findings also was not found to be significantly different(p=0.58). The PPV of having acute clinical sinusitis for a given radiographic abnormality was highest for total sinus opacification(56%), frothy secretions(53%), and fluid levels(47%) and lowest for mucosal thickening alone(13%). PPV was even greater(67%) with the combined presence of at least two abnormalities(fluid level, frothy secretions or total sinus opacification)(Table2). Using the screening sinus CT as a baseline examination, a significant difference was found in LM score change from baseline between patients who did and did not develop post-HSCT clinical sinusitis(10.4 vs. 4.2 p=<0.001). Furthermore, patients with a change in the LM score≥10 were 2.77 times more likely to have clinical sinusitis(CI:1.32-5.81).

Development of Post-HSCT Clinical sinusitis

Pre-HSCT CT findings	No. of patients	Post-HSCT sinusitis	%
Normal	***56***	***8***	***14***
Radiographic abnormalities alone			
Total	***35***	***8***	***23***
Mild Lund-Mackay	25	6	24
Mod/Severe Lund-Mackay	10	2	20
Mucosal disease alone	19	5	26
Fluid level/frothy secretion/total opacification	16	3	19
Clinical Sinusitis	***9***	***2***	***22***
Total	100	18	18

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Correlation of CT findings with clinical sinusitis in pediatric oncology patients

CT Finding	Sensitivity	Specificity	PPV	NPV
Mucosal thickening alone	19	71	***13***	78
Fluid level	26	94	***47***	87
Frothy secretion	37	94	***53***	89
Total-near total opacification	56	92	***56***	92
Multiple abnormalities	37	97	***67***	89

Conclusion
Neither the presence nor the severity of pre-HSCT radiographic sinus disease was found to significantly correlate with the development of clinical sinusitis later in the post-transplant period. However, Pre-HSCT CT scans can serve as a baseline from which subsequent scans may be compared--with LM score change≥10 a significant threshold. Radiographic findings of total sinus opacification, frothy secretions, or fluid levels have the strongest correlation with the presence of acute clinical sinusitis and may prompt further clinical workup.

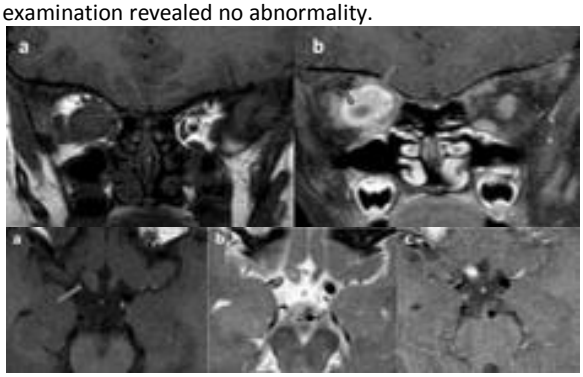
Concomitant Meningioma and Glioma within the Same Optic Nerve in Neurofibromatosis Type 1

Akça, A.·Büyükkapu Bay, S.·Karadoğan, M.·Çorapçıoğlu, F.·Anik, Y.
Kocaeli University School of Medicine
Kocaeli, TURKEY.

Purpose
We aimed to present an extraordinary case of neurofibromatosis type 1 with concomitant meningioma and glioma in the same optic nerve.
Materials & Methods
A 4-year-old boy was admitted to our hospital with right-sided proptosis. We performed ophthalmologic examination, physical examination and magnetic resonance imaging (MRI).
Results
Physical examination revealed numerous cafe-au-lait macules, axillary freckling and right-sided proptosis. On MRI a mass originating from the right optic nerve sheath with normal appearance of the optic nerve was observed which was consistent with optic nerve sheath meningioma. Another mass lesion was observed in the prechiasmatic region of the same optic nerve which was consistent with optic nerve glioma. Ophthalmologic examination revealed no abnormality.



Conclusion
Neurofibromatosis type 1 is an inherited tumor predisposition syndrome. Diagnosis can be made using the National Institutes of Health diagnostic criteria. These patients are prone to developing both peripheral and central nervous system tumors. Gliomas are the most common primary central nervous system tumors that especially are seen in the optic pathways in children. MR imaging is an excellent method of choice in the followup of patients with neurofibromatosis, as well as detecting lesions in asymptomatic patients. The diagnosis of an optic nerve glioma and optic nerve sheath meningioma can be confirmed by computed tomography or magnetic resonance imaging. Two different types of optic pathway tumors in the same optic nerve is an extraordinary case. It is important to recognize imaging findings of these tumors and make correct diagnosis because the treatments differ between these two tumors.

KEYWORDS: Neurofibromatosis, Nerve sheath tumor, optic glioma

eP-225

Atypical Characteristics and Behavior of Dysembryoplastic Neuroepithelial Tumors

Daghistani, R.[1]·Miller, E.[2]·Kulkarni, A.[3]·Widjaja, E.[3]
[1]University of Toronto, Toronto, ON, CANADA, [2]Children's Hospital for Eastern Ontario, Ottawa, ON, CANADA, [3]Hospital for Sick Children, Toronto, ON, CANADA.

Purpose
Dysembryoplastic neuroepithelial tumors (DNET) classically are considered as benign, cortically based tumors that are stable. However, there were case reports that suggest DNET may not be as benign as previously thought of. The purpose of our study was to identify atypical location, characteristics and behavior of DNET in children.
Materials & Methods

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

The MRI images of 51 patients with pathologically proven DNETs, were reviewed retrospectively. The following were assessed: tumor location, neuroimaging appearances including hemorrhage, calcification and edema, tumor growth preoperatively and after subtotal resection, tumor recurrence, malignant transformation and metastatic seeding.

Results

Two (3.9%) patients had intraventricular lesions, three (5.9%) had associated edema, three (5.9%) had calcifications and one (2%) had hemorrhage on preoperative CT and MRI. Sixteen of 51 (31.4%) of the lesions exhibited enhancement postgadolinium administration. Six of 29 (20.7%) of the preoperative lesions that had follow-up imaging were enlarging prior to surgery. In six of 18 (33.3%) with subtotal resection, there was an increase in size of the residual tumor. Tumor recurrence at the surgical bed occurred in three of 30 (10%) patients who had gross total resection. Two of 51 (3.9%) cases developed secondary lesions distant to the primary tumor, the secondary lesions were within the lateral ventricles.

Conclusion

In children, DNETs may have atypical location, characteristics and behavior, including growth of primary or residual lesions and multifocal tumor. These findings emphasize the need for followup of patients with DNET postresection.

KEYWORDS: Dysembryoplastic neuroepithelial tumor, recurrence

eP-226

Measurements of Normal Inner Ear in Children with Congenital Sensorineural Hearing Loss and a "Normal Temporal Bone CT Scan"

Bahador, F.·Darke, M.·Nabi, J.·Fallahian, A. H.
University of Missouri Health Care
Columbia, MO.

Purpose

Using standardized measurements of the inner ear to see whether there are subtle bony malformations in children with congenital sensorineural hearing loss whose temporal bone computed tomography are grossly normal.

Materials & Methods

IRB approval was obtained. Medical records and the pure-tone audiometric results of 339 patients, diagnosed with sensorineural hearing loss in our tertiary referral center were reviewed. Children with perinatal infections were excluded from the study. The high-resolution temporal bone CT scans of the remaining 112 patients were reviewed retrospectively. Patients with cochlear, labyrinthine, aqueductal or IAC anomalies also were excluded. Fifty-six patients with 90 ears, and grossly normal temporal bone CT scans met the eligibility criteria. The control subjects, who included 55 patients with 90 ears, had undergone CT for the evaluation of cholesteatoma, mastoiditis, external ear disease or trauma. The CT scans of the SNHL and the control groups were performed between June 2004 and September 2011 and between September 2005 and August 2011, respectively. Two readers including a PGY-4 radiology resident and a radiologist with 11 years experience who did not have any knowledge of the other reader's interpretations or audiometric results reviewed all CT scans independently. Standardized measurements including maximal height and length of cochlea and vestibule, canal lumen width and bony island width of superior semicircular canal (SSCC) and lateral semicircular canal (LSCC), canal lumen width and inferior limb length of posterior semicircular canal (PSCC) were made on axial and coronal CT images. Correlation was made with short and long axes to avoid error in measurements.

Results

Student's *t*-test was performed to compare the measurements of the two groups. Significant difference was noted only in width of the posterior semicircular canal between the SNHL and control groups for one of the readers, with a narrow margin of accuracy. No significant difference was noted in other nine measurements.

	Reader 1					Reader 2

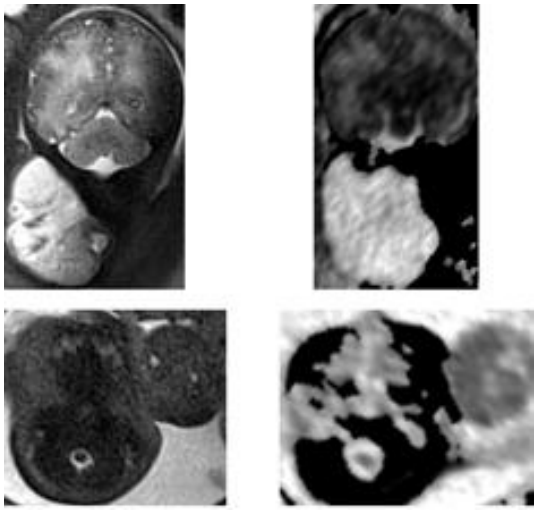
Diffusion-Weighted Imaging of Fetal Head, Neck and Spine Tumors

Mignone Philpott, C.[1]·Shannon, P.[2]·Ryan, G.[2]·Chitayat, D.[2]·Blaser, S.[1]
[1]Hospital for Sick Children, Toronto, ON, CANADA, [2]Mount Sinai Hospital, Toronto, ON, CANADA.

Purpose
Diffusion-weighted imaging can be used to characterize tumors of the head, neck and neural axis given its ability to assess the relative motion of molecules within tissue and hence degree of cell density and presumed tissue differentiation. The tumor cell type, for example, lymphoma versus carcinoma and degree of differentiation can also be inferred. MR imaging is used increasingly for better differentiation of sonographically detected tumors in the fetus, to assist in diagnosis and subsequent management. We sought to evaluate the potential utility of diffusion-weighted imaging in characterizing tumors of the head and neck in the fetus.
Materials & Methods
We identified fetuses who had MR imaging performed to evaluate a mass in the head, neck or spine in our institution over the last five years. The imaging was reviewed retrospectively with specific note made of T2, T1 signal characteristics, presence of signal drop on susceptibility-weighted sequences, size and location of the tumor. A region of interest within the tumor was drawn for assessment of ADC value. All follow-up imaging and pathology was reviewed, including postnatal biopsies and autopsies in cases where there had been termination. The ADC values of these masses were charted to see if there was any relationship between etiology and malignant potential and ADC values.
Results
There were 15 fetuses in total, 10 of whom had a pathology diagnosis, three who had postnatal MRI confirming the diagnosis and two others who were lost to postnatal followup. Three patients had a sacrococcygeal teratoma, two predominantly cystic with mature elements, the other immature, two had sarcomas: infantile hemangiopericytoma and infantile myofibromatoma, two, heterotopia, one, encephalomalacia postinfarction, another hematoma, and two, posterior fossa cystic lesions. The benign posterior fossa cystic lesions, encephalomalacia, cystic teratomas and vascular/lymphatic malformations all exhibited ADC values at least 1000 x 10-6mm2/s higher than the immature teratoma, sarcomas and the medulloblastoma (Figure 1). The T2 and SWI sequences help differentiate the heterotopic brain and hematoma from the latter cellular tumors.



Conclusion
Apparent diffusion coefficient assessment, together with traditional MR sequences and SWI, appears to be a potentially useful tool in differentiating benign from potentially malignant neural axis masses in the fetus.

Radiologic Approach to Pediatric Cervical Spine Trauma

Chopra, P. R.·Srivastava, V.·Halpin, J. S.
University of Missouri Kansas City
Kansas City, MO.

Purpose
Although cervical spine trauma is a rare occurrence in children it has the potential for severe neurologic consequences. However, if accurately diagnosed and managed, it is possible to minimize the extent of damage. This presentation will focus on the various types of cervical spine trauma and their characteristics and how to accurately diagnose cervical spine trauma in children by employing aspects of clinical history, physical examination, and appropriate imaging techniques. Our goal is to emphasize specific imaging studies that are the best tools for diagnosing cervical spine trauma, while also minimizing the amount of radiation exposure to our pediatric patients. Lateral radiographs are the initial radiographic study to screen for cervical trauma in children. When no significant finding is noted and no further clinical concern persists, no further radiographic evaluation is necessary. However, if clinical concern is present, MRI or flexion/extension radiographs are recommended.

KEYWORDS: Cervical

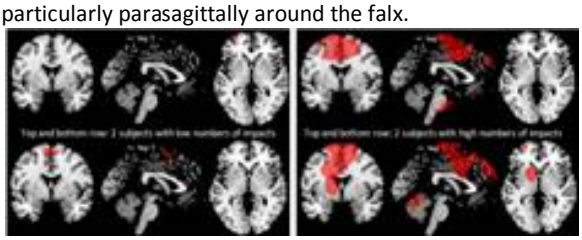
eP-229

Delta Wave Detection in Magnetoencephalographic Data of High School Football Players

Davenport, E. M.[1]·Urban, J. E.[2]·Whitlow, C. T.[1]·Powers, A.[1]·Thompson, M. M.[2]·Rawley, J.[1]·McGowin, I.[2]·Alberto, G.[2]·Bungo, T.[2]·Godwin, D.[2]·Stitzel, J. D.[2]·Maldjian, J. A.[1]
[1]Wake Forest University School of Medicine, Winston-Salem, NC, [2]Wake Forest University, Winston-Salem, NC.

Purpose
The Head Impact Telemetry (HIT) system records kinematic data from impacts received from an encoder unit installed in player helmets during football practices and games. Magnetoencephalography (MEG) is a noninvasive form of functional brain imaging that is used to further understand brain function. Injured neural tissue can produce low-frequency magnetic signals (delta waves), which can be detected using advanced processing of MEG data. The purpose of this study is to determine if high numbers of impacts experienced in a season of high school football are associated with detectable changes in MEG delta waves.
Materials & Methods
An institutional ethics committee approved this study. The total number of head impacts of 18 normal male subjects aged 16-18 years were recorded over a football season using the HIT system. Eight minutes of eyes-open, resting-state MEG data were acquired for each subject using a 275-channel CTF whole-head system pre and postseason. In addition, structural anatomical MRI was acquired using a 3T Siemens Skyra scanner with a 32-channel head coil. Using an in-house automated pipeline, MEG data were baseline corrected, band-stop filtered at 60Hz, down-sampled to 100Hz, and band-pass filtered to 1-4Hz (delta spectrum). Artifacts from head motion, and muscles were removed. Magnetoencephalography data then were projected into standard source space at 5 mm resolution using a scalar beamformer with leadfield correction for noise normalization. The time-course for each voxel then was divided into 2.5-second epochs with 50% overlap, and each epoch was fourier transformed. The average delta spectrum amplitude was recorded for each epoch, and averaged across epochs. The group mean and standard deviation of the 18 subject's preseason delta spectrum for each voxel were found, creating a control group. Subjects were separated into a high-impact group (>600 impacts, two subjects), and a low-impact group (~250 impacts, two subjects) based on the HIT data. Postseason delta band amplitudes were compared to the control group by calculating voxel-wise Z-scores for the high-impact and low-impact subjects.
Results
Figure 1 demonstrates the Z-score maps of these four subjects, thresholded at two standard deviations. The low-impact players have few areas of significant delta wave difference from the control group. The high-impact players have large areas of significant increases in delta waves, particularly parasagittally around the falx.



Conclusion
High school football players with a higher number of impacts per season may demonstrate functional changes in brain delta-wave activity that previously has been associated with head injury.

Prevalence of Subdural Collections in Children with Macrocrania

Richards, T.·Greiner, M. V.·Care, M.·Leach, J. L.
Cincinnati Children's Hospital Medical Center
Cincinnati, OH.

Purpose
To determine the prevalence of subdural collections (SDC) on cross-sectional imaging in children with macrocephaly correlating with subarachnoid space (SS) enlargement.
Materials & Methods
The radiology information system of a large pediatric medical center was reviewed for "macrocrania" and "macrocephaly" on reports of cranial MRI/CT examinations in children < 24 months of age, over a 24-month period. Head circumference (HC) was obtained from the clinical record. Studies were blind reviewed for: SDC presence and SS size. Children with prior cranial surgery, parenchymal abnormalities, hydrocephalus, or conditions predisposing to parenchymal volume loss were excluded. Chart review was performed on those with SDC.
Results
Imaging from 177 children with enlarged HC was reviewed. Nine were excluded for a final cohort of 168 subjects (108 with enlarged SS). Subdural collections were identified in six (3.6%), all with enlarged SS (6/108, 5.6%). In four, SDC were small, homogeneous, and not overtly hemorrhagic. In two cases, the collections were complex (septations or hemorrhage). Two children were reported as victims of child abuse (both with complex collections). No definitive etiology was established in the other cases.
Conclusion
The prevalence of SDC in imaged children with macrocrania is 3.6 %, all occurring in children with enlarged SS (6/108, 5.6%). Although limited by sample size, our results suggest that enlarged subarachnoid spaces are associated with some SDC in this cohort. Despite these findings, we feel strongly that every unexpected SDC in a young child, especially if complex in

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

appearance, receive close clinical evaluation for underlying causes, especially abusive head trauma. Abbreviation Key: SS = subarachnoid spaces, SDH = subdural hemorrhage, SDC = subdural collections, CT = computed tomography, MRI = magnetic resonance imaging, HC = head circumference.

Minimizing Radiation Exposure in Evaluation of Pediatric Head Trauma: Utilization of Rapid MR Imaging

Ahmad, N.[1]·Patel, B.[1]·Hira, A.[2]·Jeevan, D.[1]·LeCompte, L.[1]·Mehta, H.[1]
[1]Westchester Medical Center, Valhalla, NY, [2]University of Pennsylvania, Philadelphia, PA.

Purpose
Among children who have sustained trauma, the central nervous system is the most commonly injured isolated system. Computed tomography (CT) has been the gold-standard of imaging for initial and follow-up evaluation of head trauma in the pediatric population. Given the rampant use of CT and the concern for radiation, the pediatric radiology community has been at the forefront of radiation dose reduction in CT, fluoroscopy and radiography. Recent studies have demonstrated utilization of a rapid MRI technique to minimize radiation. In an effort to reduce radiation exposure, we aim to demonstrate rapid magnetic resonance imaging as having equal and/or increased sensitivity compared to CT, for follow-up evaluation of extra-axial and/or intraparenchymal hemorrhage in pediatric patients who have sustained head trauma.
Materials & Methods
This is a retrospective case-control study reviewing imaging of patients who sustained head trauma at Westchester Medical Center from January 2010 through January 2012. The major inclusion criteria included patients who obtained an initial head CT and a follow-up rapid MRI. Our rapid MRI sequences include: axial echo-planar imaging (EPI) diffusion-weighted; axial EPI T2, axial turbo spin-echo T2; axial single-shot FLAIR; axial single-shot T2; and coronal turbo spin-echo T2-weighted. All imaging was blindly re-interpreted by a board-certified neuroradiologist for specific parameters including: extra-axial hemorrhage (epidural, subdural, subarachnoid, intraventricular); intraparenchymal contusion/shear injury; and skull fractures. The sensitivity and specificity of rapid MRI was calculated.
Results
There are a total of 49 pediatric patients (age range 0-19 years; 26 M and 23 F) who sustained head trauma. On average, the patients underwent a follow-up rapid MRI within 48 hours or less from time of initial head CT. Our results demonstrate that rapid MRI has a sensitivity of 94% and specificity of 93% for detection of extra axial hemorrhage. Rapid MRI is superior to CT in the detection of contusion/shear injury. In detection of calvarial fracture rapid MRI has a sensitivity of 72% and a specificity of 95%. Eight patients had hemorrhagic contusion and/or shear injury identified on follow-up rapid MRI but not on initial CT. Possible explanations for this include: rapid MRI is superior in detection of contusion/shear and/or contusions/shear injury may have developed in the interim time period between the CT and follow-up MRI.
Conclusion
MR imaging is an adequate examination for follow-up imaging in lieu of repeat CT in the management of acute traumatic brain injury in the pediatric population. Given the diminished sensitivity of rapid MRI in detection of fracture, it may not act as a replacement for initial CT examination.

KEYWORDS: Traumatic brain injury, MR imaging brain

eP-232

Role of Apparent Diffusion Coefficient Values in the Evaluation of Pediatric Head Injury: Abusive Head Trauma May Not Differ from Nonabusive Head Trauma

Siddiqui, A.·Ceschin, R.·Panigrahy, A.·Berger, R. P.·Zuccoli, G.
Children's Hospital of Pittsburgh
Pittsburgh, PA.

Purpose
Differences in the severity and mechanism of a traumatic brain injury suggest that the resulting biochemical response may differ. Apparent diffusion coefficient (ADC) changes in abusive head trauma (AHT) are usually felt to be at least in part secondary hypoxic-ischemic injury after apnea, hypotension, strangulation, or suffocation. To the contrary in nonabusive head trauma (NHT) changes in ADC values are reportedly associated with diffuse axonal injury (DAI). The purpose of this retrospective observational study is to investigate brain injuries on ADC MRI sequences in subjects with AHT and compare these findings with subjects with NHT.
Materials & Methods
This was an institutional board review protocol study of 88 patients. Excluding patients with a history of respiratory arrest/failure, cardiac arrest, profound hypotension before MR, left a NAT cohort of 25 patients with mean age of 5.89 months and AT cohort of 11 patients with a mean age of 12 months. First, ADC maps of the genu, splenium, caudate, thalamus and putamen were measured manually via a standard region of interest (ROI) through a DICOM receiver. Then whole brain ADC values were measured using Linux-based neuroimaging program software (FSL). Models were adjusted for age, age-squared and GCS.
Results
No structure or Glascow Coma Scale (GCS) factor held a p-value under 0.10. Thus, there was not a statistical difference between the two populations. For the AHT

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

population, the ADC values (and standard deviations) were as listed: whole brain, 1.110 x 10^{-3} mm^2/s (194); genu, .974 x 10^{-3} mm^2/s (321); splenium, .890 x 10^{-3} mm^2/s (249); caudate, .968 x 10^{-3} mm^2/s (172); thalamus, .897 x 10^{-3} mm^2/s (147); and putamen, .963 x 10^{-3} mm^2/s (171). For the NHT population, the ADC values were as listed: whole brain, 1.084 x 10^{-3} mm^2/s (175); genu, .919 x 10^{-3} mm^2/s (236); splenium, .932 x 10^{-3} mm^2/s (252); caudate, .949 x 10^{-3} mm^2/s (173); thalamus, .916 x 10^{-3} mm^2/s (124); and putamen, .906 x 10^{-3} mm^2/s (176).

Conclusion

Our results displayed that ADC values between AHT and NHT do not differ. These findings suggest that ADC alone does not seem helpful in distinguishing AHT from NHT.

KEYWORDS: ADC, Pediatric brain, Abusive Head Trauma

Automated Machine Learning Analysis of Systematic Radiologic Phenotyping in Diseases Associated with Intracranial Calcification

Stivaros, S. M.[1,2]·Mileva, R.[1]·Gledson, A.[1]·van der Knaap, M. S.[3]·Keane, J.[1]·Crow, Y.[1]·Livingston, J.[4]
[1]University of Manchester, Manchester, UNITED KINGDOM, [2]Royal Manchester Children's Hospital, Manchester, UNITED KINGDOM, [3]VU University Medical Center, Amsterdam, NETHERLANDS, [4]Leeds General Infirmary, Leeds, UNITED KINGDOM.

Purpose

Intracranial calcification (ICC) often is considered an epiphenomenon of low diagnostic specificity. It occurs in both acquired/genetic conditions and also may be seen in asymptomatic individuals. To our knowledge there has been no systematic modelling of the radiologic phenotypes associated with ICC. In the leukoencephalopathies such a strategy has enabled the characterization and earlier diagnosis of specific disorders and the identification of previously unrecognized diseases, which in turn has facilitated the identification of causative genes. We present a systematic language-based model for the radiologic phenotyping of ICC which, in combination with advanced machine learning techniques allows for automated diagnostic stratification, the performance of which exceeds that of individual experts alone.

Materials & Methods

Two hundred twenty-four CT scans from 184 patients were sent to our group for review due to our interest in ICC. Infective causes had been excluded prior to referral. A range of diagnoses were established after referral by a combination of radiologic, genetic and clinical assessment in 107 patients. In the remaining 77 cases the diagnosis remained unknown. By a process of iterative reporting a systematic language-based model of ICC appearances on CT was derived. This was used to capture the imaging appearances of all scans into a novel data-construct. Multiple data analysis techniques were applied to the imaging model including Automated Decision Tree analysis, Cluster analysis, Bayesian analysis and Support Vector Machine analysis. Diagnostic stratification was performed for AGS versus all other diagnoses as well as multiple stratifications including AGS vs Cerebroretinal Microangiopathy with Calcifications and Cysts (CRMCC) vs all other known vs all unknown diagnoses.

Results

The mean age of referred patients was 5.9 years with a median age of 1.33 years (range 0.02-59 years). The diagnostic accuracy of the referring centers was of the order of 26%. The systematic language-based radiologic phenotype model was comprised of a dataset of 80 binary nominal attributes. An Averaged One-Dependence Estimator performed best at classifying cases into either AGS versus all other diagnosis with a sensitivity of 87%, specificity of 90%, and area under ROC of 92%. For stratification into AGS vs CRMCC versus known versus unknown diagnoses a C4.5 algorithm with adaptive boosting yielded the best results with sensitivity and precision of 86% and ROC area of 93%.

Conclusion

Here we present data to illustrate that a systematic approach to the radiologic phenotyping of ICC with machine-learning analysis can yield significant improvements in radiologic diagnostic accuracy. Further work will include the integration of MRI data and a prospective analysis of diagnostic performance. Taken in clinical context such techniques allow for the identification of specific disorders associated with ICC. Whilst the number of pathognomonic patterns may be limited, we consider that this strategy will both aid the diagnosis of particular conditions, and allow for the exclusion of disorders incompatible with the observed neuroimaging pattern. Furthermore, new phenotypes may be identified and the underlying genetic basis may in the future be determined through the use of such methodologies.

Update on Neuroradiologic Findings in Aicardi-Goutières Syndrome: Expanding the Phenotype

La Piana, R.[1]·Orcesi, S.[2]·Olivieri, I.[2]·Crow, Y.[3]·Uggetti, C.[4]
[1]Montreal Neurological Institute, Montreal, QC, CANADA, [2]C. Mondino Neurological Institute, Pavia, ITALY, [3]University of Manchester, Manchester, UNITED KINGDOM, [4]San Carlo Borromeo Hospital, Milano, ITALY.

Purpose

Scientific understanding of Aicardi-Goutières syndrome (AGS) has increased dramatically in the last six years. Consequently, an increasing number of cases of AGS are being identified. The aim of our study was to review the neuroradiologic findings of AGS in light of recently acquired insights into disease pathogenesis and phenotype. In particular, our goals were: a) to verify the

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

presence of neuroradiologic diagnostic criteria (leukodystrophy, atrophy, brain calcifications); b) to update the diagnostic neuroradiologic criteria by modifying the existing ones and/or by adding newly identified.
Materials & Methods
Patients were ascertained by referral to the C. Mondino Neurological Institute in Pavia, the International Aicardi-Goutières syndrome Association (IAGSA), and the Nuclease Immune Mediated Brain and Lupus-like conditions (NIMBL) project funded by the European Union (7th Framework Programme). The inclusion criteria were the following: genetic and/or clinical diagnosis of AGS; availability of at least one brain MRI study and one head CT scan of diagnostic image quality; availability of clinical information (age at onset, clinical presentation, clinical evolution, presence of extraneurologic features).
Results
We reviewed brain MRI and CT scans of 46 cases diagnosed with AGS. Of these, 36 had been reported in a previous study, whilst 10 cases (21.7%) were newly ascertained. In comparison to the previous reports, no new patterns of white matter alterations were observed. The two patterns (fronto-posterior gradient versus diffuse involvement) thus, are confirmed. In four cases with diffuse pattern, a relative sparing of the perirolandic region was defined. Brain calcifications were observed in all new diagnosed cases. Unusually, calcifications were limited to the cerebellar vermis in one subject with a clinical diagnosis of AGS (where genetic analysis of AGS1-6 was negative). In comparison to the previous reports, brain atrophy was not a relevant neuroradiologic finding in five new cases. New pathologic findings, not previously reported, were identified in the region of the basal ganglia in three patients (6.5%; 3/46), one with AGS1 mutation, two with AGS6.
Conclusion
Aicardi-Goutières syndrome was an underdiagnosed disease until the early 2000s. The availability of genetic testing, and the subsequent identification of new disease-associated genes, has led to a dramatic increase in the number of cases diagnosed since 2006. As a corollary of this, an expansion of the phenotype has been documented, both in clinical and neuroradiologic terms. We believe that the results of our study will prove helpful in directing diagnostic testing in patients with suspected AGS.

New Cerebellar Neuroimaging Findings in Mucopolysaccharidoses Types I and II

Alqahtani, E.[1]·Huisman, T. A. G. M.[1]·Boltshauser, E.[2]·Scheer, I.[2]·Güngör, T.[2]·Tekes, A.[1]·Maegawa, G. H.[1]·Poretti, A.[1]
[1]The Johns Hopkins University, Baltimore, MD, [2]University Children's Hospital of Zurich, Zurich, SWITZERLAND.

Purpose
The mucopolysaccharidoses (MPS) is a heterogeneous group of rare lysosomal storage diseases characterized by the accumulation of glycosaminoglycans. Common neuroimaging findings include enlargement of the perivascular spaces (PVS) mostly within the periventricular white matter, signal abnormalities of the supratentorial white matter, ventriculomegaly and cortical atrophy. Posterior fossa findings have been addressed less commonly in the neuroimaging literature. Our study aims to extend the spectrum of neuroimaging findings in patients with MPS focusing on the posterior fossa.
Materials & Methods
The inclusion criteria were 1) the diagnosis of MPS based on abnormal enzyme assays and/or genetic analysis and 2) the availability of at least one MRI study of diagnostic quality including 3D T1- and axial T2-weighted images. All available images were evaluated retrospectively with semiquantitative measurement and qualitative analysis of the PVS (size and location), ventriculomegaly (size), cerebral atrophy (degree of severity), supratentorial white matter (degree of signal abnormality), cerebellum and posterior fossa (size), the presence of a mega cisterna magna, acquired tonsillar ectopia, cranial vault hyperostosis and morphologic abnormalities of the sella, and stenosis at the level of the foramen magnum (degree of severity).
Results
Ten patients could be included in the study (nine males and one female). Seven patients have MPS type I; three patients have MPS type II. At the time of the most recent MRI, the median age was 9.9 years (mean age 10.1 years, range 1.8 to 28.8 years). Longitudinal MR studies were available for four patients. Supratentorial findings included enlarged PVS in all patients (mostly involving the parieto-occipital white matter) and ventriculomegaly, white matter signal abnormalities, and cerebal atrophy in six patients. Infratentorially, PVS were enlarged at the level of the brain stem in eight and at the level of the cerebellum in five patients (bilaterally in four, unilaterally in one patient). Over time, in two patients cerebellar PVS's enlargement increased, while it decreased in two other patients. In two patients we found a macrocerebellum, in one a mega cisterna magna. In one patient, a macrocerebellum became apparent over time. An acquired tonsillar ectopia or cerebellar atrophy was not found in any patient. Cranial vault hyperostosis was present in seven patients and stenosis of the foramen

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

magnum and morphologic abnormalities of the sella in four.
Conclusion
Enlargement of the PVS in the cerebellar white matter was present in 50% of our study population and was variable over time. Macrocerebellum was found in two patients and developed over time in one. Both enlargement of the cerebellar PVS and macrocerebellum have not been reported previously in MPS patients. Neuroradiologists should be aware that posterior fossa involvement is not uncommon in MPS type I and II and consequently should carefully evaluate the cerebellum and brain stem in these patients. The clinical significance of cerebellar involvement in MPS patients is unclear and should be assessed in larger cohort of patients.

Neuroradiologic Findings of Biotin-Responsive Basal Ganglia Disease

Al Sheikh, F.[1]·Al Adwani, N.[1]·Al-Shafi, S.[1]·Al Shahwan, S.[1]·Tabarki, B.[1]·Zuccoli, G.[2]
[1]Prince Sultan Military Medical City, Kingdom of Saudi Arabia, SAUDI ARABIA, [2]Children's Hospital of Pittsburgh, Pittsburgh, PA.

Purpose
Biotin-responsive basal ganglia disease (BBGD, OMIM#607483) or thiamine transporter-2 deficiency is an inherited treatable neurometabolic disease resulting from mutations in the SLC19A3 gene. Early treatment with thiamine and biotin result in normal outcome. Severe neurodevelopmental outcome and even death is observed in untreated patients. The objective is to investigate the neuroradiologic features of BBGD, and to clarify the disease spectrum.
Materials & Methods
Thirteen patients with a genetically proven diagnosis of BBGD between 2009 and 2012 were investigated by MRI brain/MRS during the acute phase and followup.
Results
We enrolled 13 patients that met the diagnostic criteria for BBGD. The BBGD occurred predominantly in preschool/school aged patients. The typical clinical picture consisted of recurrent subacute encephalopathy leading to coma, seizures, and extrapyramidal manifestations. During the acute crisis, brain MRI revealed bilateral and symmetrical involvement of the striatum in all patients. Nine (70%) patients showed symmetric involvement of the medial dorsal nucleus of the thalamus. Seven (54%) patients showed involvement of the brainstem nuclei. Ten (77%) patients showed extensive involvement of the cortex. Nine (70%) patients showed alterations in the cerebellar cortex and vermis. One patient (6%) showed involvement of the periventricular regions of the third ventricle. None of our patients disclosed subcortical white matter involvement. Vasogenic edema was identified in the affected brain regions during the acute phase the disease. None of the patients showed cytotoxic edema. MR spectroscopy was obtained in six patients disclosing decreased N-acetyl-aspartate and increased lactate peaks. Follow-up MRI showed evolving brain lesions consistent with remote injury: gliosis and atrophy were present, particularly in the striatum.
Conclusion
Biotin-responsive basal ganglia disease is an under diagnosed pan-ethnic treatable condition. Clinicians treating patients for unexplained encephalopathy and neuroimaging showing vasogenic edema in the bilateral striatum, infra and supratentorial cortex and brainstem, should consider this disorder early in the hospital course as a therapeutic trial with biotin and thiamine can be lifesaving.

Comparison of MR Imaging Characteristics at Time of Multiple Sclerosis Onset between Pediatric Patients and Adults: A Retrospective Data Analysis

Milos, R.[1]·Szimacsek, M.[1]·Pritsch, M.[2]·Penzien, J.[3]·Karenfort, M.[4]·Blaschek, A.[5]·Seidl, R.[1]·Rostasy, K.[6]·Bayas, A.[7]·Storm van's Gravesande, K.[8]·Prayer, D.[1]·Kornek, B.[1]
[1]Medical University of Vienna, Vienna, AUSTRIA, [2]DRK-Children's Hospital, Siegen, GERMANY, [3]Children's Hospital Klinikum Augsburg, Augsburg, GERMANY, [4]Heinrich Heine University Düsseldorf, Düsseldorf, GERMANY, [5]Dr. von Hauner's Children's Hospital - Ludwig-Maximilians University, Munich, GERMANY, [6]Innsbruck Medical University, Innsbruck, AUSTRIA, [7]Klinikum Augsburg, Augsburg, GERMANY, [8]Gottfried von Preyer Children Hospital, Vienna, AUSTRIA.

Purpose
There are many similarities between pediatric- and adult-onset multiple sclerosis (MS), however patients with disease onset before the age of 18 have a higher relapse rate and seem to present more often with brainstem symptoms. Only few studies have compared magnetic resonance imaging (MRI) findings at disease onset between patients with pediatric- versus adult-onset MS. Therefore the aim of this study was to compare the imaging characteristics of the brain and spinal cord between children and adults at MS onset. Furthermore we evaluated the 2010 McDonald criteria in both groups.
Materials & Methods
We analyzed retrospectively clinical and MRI data from 52 patients (33 women and 19 men) with pediatric-onset MS (mean age 14.36 ± 1.91 years) and 42 patients (22 women and 20 men) with adult-onset MS (mean age 29.97 ± 8.39

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

years). The minimum MRI protocols required the following sequences: axial and sagittal T2-weighted or FLAIR, T1-weighted before and postgadolinium for brain and sagittal T2-weighted and T1-weighted before and postgadolinium for spinal cord. The following parameters were assessed: initial symptoms at disease onset, presence of oligoclonal bands in the cerebrospinal fluid, mean time from first demyelinating attack to first brain and spinal MRI, number of focal T2 hyperintense, T1-hypointense, gadolinium-enhancing, and giant (over 2 cm in diameter) lesions and lesions distribution in brain and spinal cord.
Results
All patients showed symptoms characteristic for MS, including optic neuritis, brainstem/cerebellar or spinal cord syndrome or a syndrome attributed to cerebral hemispheres (sensory and/or motor dysfunction). Oligoclonal bands were positive in 94% of children and 80% of adults. The time between symptoms onset and first brain scan was similar between children and adults (mean 0.76 versus 0.88 months), while for the spinal scan there was a longer delay in children (mean 1.56 versus 0.9 months). We found no significant differences in the number and distribution of cerebral lesions between the two groups, although there was a tendency for children to have more frequent an infratentorial involvement (59.61% versus 42.85% of patients). Likewise, there were no significant differences in the number and size of spinal lesions between the two groups. Adults more frequently had enhancing cord lesions (52.94% versus 24% of patients), as well as predominantly only thoracical located lesions (23.8% versus 3.84%). In contrast, children more often had simultaneous cervical and thoracic lesions (50% versus 28.57%). At clinical onset the 2010 McDonald criteria were fulfilled as follows: the dissemination in space (DIS) in 88.23% of children and in 87.5% of adults, the dissemination in time (DIT) in 54.16% of children and 39.39% of adults and both DIS and DIT in 52.08% of children and 40.62% of adults.
Conclusion
In our cohort of pediatric and adult onset MS we did not find a major difference in the initial MRI presentation, although a trend was noted for a higher infratentorial involvement in children and more frequent contrast-enhancing lesions in adults. With respect to the McDonald criteria the demonstration of DIT as well as both DIS and DIT was higher in pediatric patients.

eP-238

MR Imaging Findings in Childhood Posterior Reversible Encephalopathy Syndrome: What is Different Than the Adults?

Donmez, F. Y.·Guleryuz, P.·Agildere, M.
Baskent University
Ankara, TURKEY.

Purpose
Posterior reversible encephalopathy syndrome (PRES) is a clinical scene presenting with convulsion, vision abnormalities, altered mental status and headaches in the presence of an underlying etiology and diagnosis can be made by support of radiologic studies. In this study, we evaluated the MRI findings of PRES in children and compared our findings with that of the known features in adult patients, and find the pathophysiologic reason that may cause the difference.
Materials & Methods
Twenty-nine children (13 male, 16 female, aged 1-17 years, mean age 10 years) diagnosed as PRES clinically and by radiologic workup were reviewed retrospectively. Clinical records were analyzed for the clinical symptoms at the time of MRI study and the underlying etiology. MR images were evaluated for the distribution of the lesions, contrast enhancement, diffusion restriction and any complication such as hemorrhage.
Results
Twenty-four of the patients presented with seizure, five had altered mental status, one patient had vision abnormality and one had ataxia. Underlying etiologies were variable: Chronic renal disease (n:8), leukemia (n:3), lymphoma (n:3), Wilson's disease (n:3), acute hepatitis (n:3), liver transplant recipient (n:3), hemolytic uremic syndrome (n:2), hemophagocytic syndrome (n:2), aplastic anemia (n:1) and metastatic osteosarcoma on chemotherapy regimen (n:1). Mean blood pressure was 130/85. Parietal (90%) and occipital (72%) involvement are the most common findings as expected; however, frontal lobe (66%) edema also is not uncommon, with rates close to occipital involvement. Temporal lobes were only involved if the edema was extensive in all parts of the brain (21%). Isolated temporal lobe involvement in absence of parietooccipital edema was not seen. The most interesting finding was the cerebellar involvement which was present in almost half of the patients (48%) and which was also atypical in adult patients. There were two patients with atypical presentation, with involvement of the thalami and basal ganglia and the brainstem. Contrast enhancement is also another finding which was found more common than the adults (39%). Twenty-six patients had diffusion-weighted imaging, diffusion restriction was seen in four of them (15%) and four patients had hemorrhage (15%); which are almost the same frequencies as in the adults.
Conclusion
The explanation of the posterior involvement related to

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

lack of sympathetic innervation of the arterioles supplied by the vertebrobasilary system also is not entirely correct in children with PRES. However, the increased incidence of cerebellar involvement may show that the posterior circulation in children is more vulnerable than the adults. The contrast enhancement which is seen more common than in the adults may show that the pathophysiology in children may be related to blood-brain barrier breakdown more commonly, which can support the theory of the toxic endothelial injury. Mean blood pressure was not very high in our study group, only some of the children with kidney diseases had hypertension, which also makes it not possible to explained the syndrome solely by hypertensive effects and promote the toxic endothelial injury theory to be more commonly encountered in children with PRES.

KEYWORDS: PRES, Childhood, MR imaging

Neuroimaging Findings in Rare Case of Navajo Neurohepatopathy (MPV 17-Related Mitochondrial Depletion Syndrome)

Malhotra, A.·Kalra, V.·Rao, B.·Jubinski, P.·Mistry, P.
Yale University
New Haven, CT.

Purpose
To present the neuroimaging findings in a rare case of Navajo neurohepatopathy (MPV 17-related mitochondrial depletion syndrome).
Materials & Methods
MPV 17-related hepatocerebral mitochondrial depletion syndrome (MDS) is a rare congenital autosomal recessive disorder characterized by hepatic failure, failure to thrive and neurologic findings. Three phenotypes have been described based on age at onset - infantile (onset before age six months), childhood (onset between ages one and five years) and classic form (after age five). The classic form tends to have moderate liver dysfunction with progressive neuropathy. There are only a few cases described in the literature with description of involvement of cerebellar white matter, cerebellar peduncles, substantia nigra and dorsal brainstem.
Results
A 9-year-old girl presented with liver dysfunction due to cirrhosis and the initial liver biopsy showed abnormal copper deposits in the liver, although genetic testing was negative for Wilson's disease. She underwent liver transplant and did well on immunosuppression for eight months. She presented with ataxia and progressive decline in neurologic function. Initial MRI showed bilateral basal ganglia ring-enhancing lesions. Multiple nodular lesions were found in the lungs and kidneys, and the lung biopsy revealed post-transplant lymphoproliferative disorder (PTLD), likely polymorphic. The patient was treated with chemotherapy. The patient had sequential brain imaging over four months, which showed appearance of multiple scattered hemorrhagic lesions which were felt to be due to PTLD. The patient developed T2 hyperintense signal in the dorsal cervical cord and subsequently restricted diffusion in the bilateral pyramids and reticular formation extending cranially along the inferior cerebellar peduncles with additional foci in the periventricular white matter abutting the third ventricle, occipital horns and atria of lateral ventricles and in the corpus callosum. These findings progressively worsened over 6 weeks with persistent low ADCs, before the patient expired.
Conclusion
We present a very rare case of classic form of MPV 17-MDS with sequential neuroimaging findings. Merkle et al (AJNR Am J Neuroradiol 33:E34 -E35 Mar 2012) previously described the involvement of reticulospinal tracts and descending reticular activating system. Diffusion-weighted images were particularly helpful in our case in following the CNS involvement. Awareness of this entity and its neuroimaging findings will help in early identification and appropriate genetic counseling.

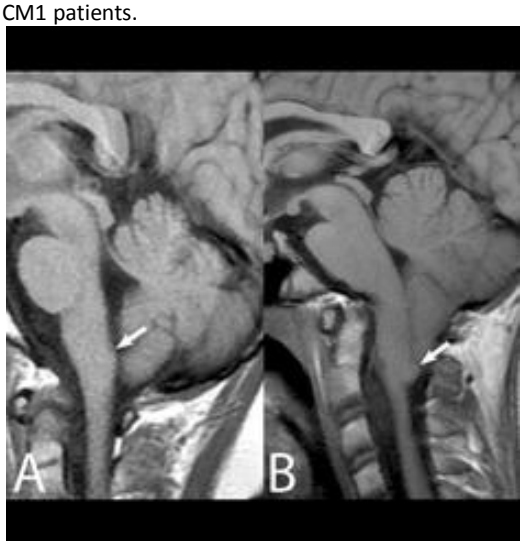
Obex Level in Normal Subjects Compared to Chiari 1 and Complex Chiari Malformation Patients

Moore, H. E.[1]·Moore, K. R.[2]
[1]Scripps College, Claremont, CA, [2]Primary Children's Medical Center, Salt Lake City, UT.

Purpose
The obex is used as a surgical landmark for the cervicomedullary junction, and it is detectable on MR imaging. Low obex level, indicative of hindbrain herniation, has been described in both Chiari 1 malformation (CM1) and complex Chiari malformation (CCM). We hypothesize that the obex level in CM1 and CCM brains is statistically significantly different from the obex level in normal brains.
Materials & Methods
Eight-four control subjects were identified during an institutional imaging database search using the search term "normal brain". Subjects 18 years of age were excluded. All control subject brain MRI exams were confirmed to be normal. Eighty-five CM1 and 66 CCM patient MRI exams also were evaluated. Obex level was measured in all 235 control and patient subjects. Cerebellar tonsil level, craniocervical angle (CXA), and odontoid retroflexion (pB-C2) also were compared among the control, CM1, and CCM brains.
Results
The obex resided above the foramen magnum in all control subjects. The obex was lower in the CM1 and CCM patients; however, with statistically significant inferior obex displacement as compared to normal control subjects. The cerebellar tonsils were normally positioned (< 5 mm below foramen magnum) in all control subjects. Cerebellar tonsillar descent (ectopia) was statistically

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

significant in the CM1 and CCM patients as compared to controls. Within the control group, average pB-C2 measured 4.6 mm and CXA 160 degrees. CXA was statistically significantly smaller and pB-C2 larger between control and CCM patients but not between control and CM1 patients.



Conclusion
The obex level resides above the foramen magnum in normal subjects, but it is consistently displaced inferiorly in CM1 and CCM patients. Cerebellar tonsillar ectopia is always present in CM1 and CCM patients but not in normal subjects. Odontoid retroflexion and reduced CXA are common in CCM but less consistently observed in CM1 patients.

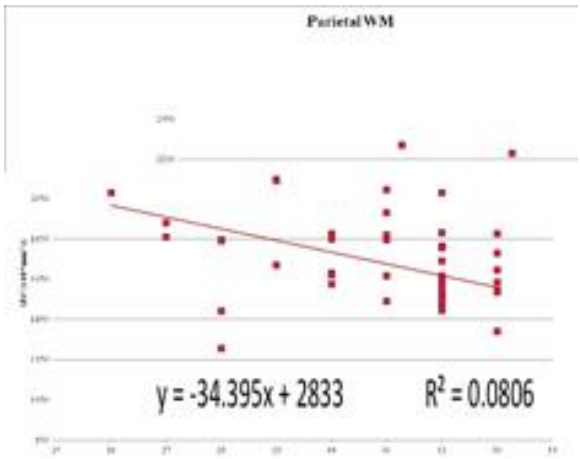
Apparent Diffusion Coefficient Value of Developing Normal Fetal Brain

Hoffmann, C.[1]·Katorza, E.[1]·Weisz, B.[1]·Tsarfati, G.[1]·Biegon, A.[2]
[1]Sheba Medical Center, Ramat-Gan, ISRAEL, [2]Brookhaven National Laboratory, New York City, NY.

Purpose
The apparent diffusion coefficient (ADC) value of the brain tissue changes during the maturation process of the brain. It is important to establish the normal values for each gestational week in order to distinguish the abnormal values from the normal ones.
Materials & Methods
Forty-eight women underwent MRI in the third trimester (26-33 weeks GA). The indication was siblings with metabolic diseases in previous pregnancies and normal US, and cases in which an anatomical abnormality was suspected, but the MRI excluded the condition. The ADC value was measured in nine locations on both hemispheres and in the posterior fossa.
Results
The ADC value declines during the third trimester in all the ROIs, excluding the frontal lobe. The difference is not significant between each consecutive week. The ADC value is lower in the gray matter and in the brain stem than in the white matter.



Conclusion
The ADC value in the white matter is higher than in the gray matter. During pregnancy the process of myelination takes place so the ADC value has a tendency to be lower.

KEYWORDS: Diffusion-weighted imaging, 1.5T, normal development

eP-242

Enlargement of the Internal Auditory Canal in PHACES Association

Meltzer, D. E.[1]·Blei, F.[2]·Robson, C.[3]·Holliday, R. A.[4]
[1]St. Luke's-Roosevelt Hospital Center, New York, NY, [2]Vascular Birthmark Institute of New York, New York, NY, [3]Boston Children's Hospital/Harvard Medical School, Boston, MA, [4]New York Eye and Ear Infirmary, New York, NY.

Purpose
Posterior fossa malformations, hemangiomas, arterial anomalies, cardiac defects, eye abnormalities, and sternal defects comprise the PHACES association. The segmental facial hemangiomas of PHACES association are frequently associated with ipsilateral cerebellar hypoplasia and ipsilateral anomalies of the intracranial internal carotid artery. Recently, attention has been drawn to the incidence of intracranial hemangiomas, especially in the internal auditory canal (IAC) and cerebellopontine angle cistern. In our experience with PHACES association patients, we have noticed several patients with enlargement of the IAC. We questioned whether this finding represented residual osseous enlargement secondary to an IAC hemangioma. The purpose of this

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

study was to document the incidence and imaging appearance of anomalies of the IAC and posterior fossa in patients with PHACES association.
Materials & Methods
All 46 patients underwent MR imaging of the brain. Intravenous gadolinium was administered to 37 of these patients. Forty-two patients ranged in age from eight days to 10 years at the time of initial imaging. Four patients ranged in age from 16-25 years. CT examinations were available for review in 10 of patients. Three neuroradiologists with at least eight years of experience interpreting neuroradiologic imaging studies retrospectively reviewed images of the brain from patients with PHACES association. The focus was to document the presence of posterior fossa anomalies. Specifically, these included cerebellar hypoplasia, enlargement (and anomalous craniocaudad tilt) of the internal auditory canal (IAC), prominence of the posterior petrous ridge, and hypoplasia of the overlying occipital bone.
Results
Sixteen patients demonstrated a combination of cerebellar hypoplasia, ipsilateral enlargement of the IAC, and ipsilateral prominence of the posterior petrous ridge. Eight of these 16 patients also had ipsilateral hypoplasia of the overlying occipital bone. Five patients had ipsilateral posterior fossa enlargement with a prominent CSF space around the hypoplastic cerebellum. Three patients demonstrated a hemangioma in the IAC. Two patients demonstrated asymmetric IAC enhancement without definable mass. Of the five patients with abnormal IAC enhancement, one did not demonstrate enlargement of the IAC.
Conclusion
Thirty-five percent of the PHACES patients in this retrospective review had IAC enlargement, ipsilateral to their cerebellar hypoplasia, with associated anomalous tilt of the affected IAC, and mild ipsilateral prominence of the petrous ridge. Only nine percent of the PHACES patients demonstrated evidence for IAC hemangioma. The results do not support our original theory of a causative relation between IAC hemangioma and IAC enlargement. The results raise the alternative possibility that the enlarged IAC in PHACES is related to a generalized malformation of the osseous components of the posterior fossa in association with cerebellar hypoplasia. Associated ipsilateral hypoplasia of the overlying calvarium is an additional, less consistent, finding in these patients.

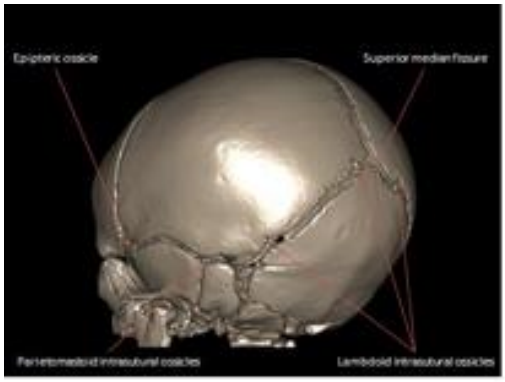
Normal Calvarial Variants Portrayed by 320 Detector 3D Volumetric CT

Whitehead, M. T.·Choudhri, A.
University of Tennessee
Memphis, TN.

Purpose
Normal variant intrasutural ossicles, fissures, foramen, and asymmetries are commonplace in the developing calvarium. As CT technology has advanced, normal variant anatomy has become increasingly recognizable. Radiologists should be readily aware of normal variants so as to prevent misdiagnoses. We performed a retrospective review of 2D and 3D CT datasets to determine type, location, number, and symmetry of normal calvarial variations.
Materials & Methods
Two hundred eighty-eight consecutive CT scans performed on children under two years of age in a 12-month period at a single academic medical center were evaluated. Studies with craniofacial abnormalities, excessive motion artifact, ventricular shunts, prior intracranial surgery, and studies with no available 3D reconstructions were excluded. Two hundred thirty-five studies met inclusion criteria (ages 0.85+/-0.63 years, range 0.00 to 2.82 years, median 0.7 years). Three-dimensional CT data sets displayed at 18 degree intervals in tumble and rotation were reviewed for the location, number, and symmetry of intrasutural ossicles, fissures, and foramen. Studies were reviewed in a blinded manner by two fellowship-trained neuroradiologists with ABR subspecialty certificates in neuroradiology. A consensus reading was reached in all cases.
Results
The vast majority of patients had intrasutural ossicles (84%; 199/235; range 0 to 25, median 3), principally located in the lambdoid sutures (70%; 165/235; range 0 to 22, median 2). Intrasutural ossicles were not identified in the metopic, sphenotemporal, and parietosquamosal sutures in any patient. There was striking variability regarding number and symmetry of these intrasutural ossicles. Short segment parietal fissures were present in several patients (17%; 41/235) in two distinct locations, unilaterally or bilaterally terminating in the lambdoid sutures. Unilateral or bilateral parietal foramina near the vertex midline were present in some patient (37%, 86/235), most of which were tiny in size.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Conclusion
Normal variant intrasutural ossicles, fissures, and foramen are a very frequent occurrence in the developing calvarium and should not be mistaken for pathology. Most patients less than two years of age have intrasutural ossicles. Asymmetric ossicles and fissures can be distinguished from fractures by their characteristic locations and appearances. Deviations from the normal pattern of calvarial variants should raise suspicion for possible pathologic processes.

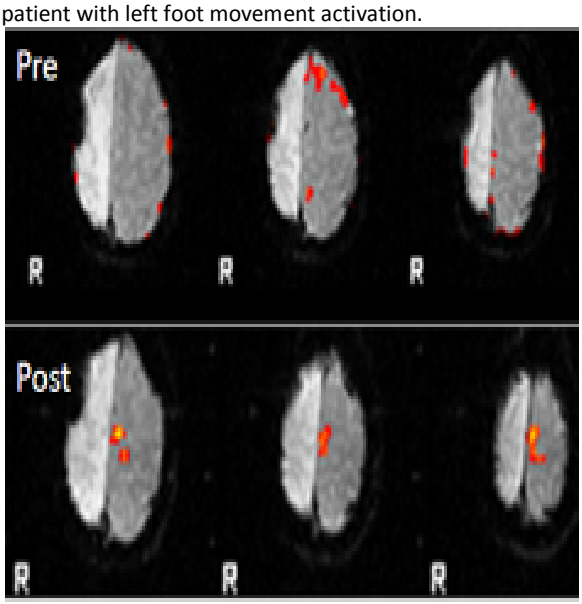
Functional Neuroimaging of Patients with Posthemispherotomy Pre and Postintensive Gait Therapy

Salamon, N.·DeBode, S.·Bookheimer, S.
University of California Los Angeles
Los Angeles, CA.

Purpose
Many patients with intractable epilepsy underwent hemispherotomy for seizure control, plasticity and reorganization of the motor control may develop after surgery. We studied motor and gait functions pre- and post-body weight support treadmill (BWST) training, and correlate changes from training using functional MRI (fMRI) cortical activation from voluntary knee movements. Our goals are to exploit functional plasticity in the developing human brain by determining if age at injury/surgery, related to specific pathologies, predicts baseline motor/gait functions and response to BWST training.
Materials & Methods
Diffusion Tensor Imaging: An axial 2D EPI based diffusion-weighted sequence (Siemens Allegra 3.0T TE/TR 129/6000 ms, FOV 240 x 240 mm, Matrix 128 x 128 interpolated to 256 x 256, Slice thickness 2 mm, Number of slices 70) will be acquired with diffusion gradients along 32 noncollinear directions at two b values of 600 sec/mm2 and 1200 sec/mm2. Functional MR Imaging: Functional MRI analysis will be obtained using motor sensory testing using knee movement. Control and five posthemispherectomy patients had received BWST training and pre- and post-fMRI was performed. Data analysis was made using a statistical program (Stat View SAS Institute, Cary, NC). Differences between control and hemispherectomy patients were compared using t test and repeated-measured analysis of variance. Comparisons using nominal variables were performed using chi-square tests. Results were considered at a minimal level of significance of P<.05.
Results
For hemispherectomy patients, the increase in activation of the voxel was obtained in ipsilateral paretic and contralateral nonparetic movements (p<.02) after BWST. For control subjects, there was decrease in activity in the voxels after BWST. Attached image demonstrates pre- and post-BWST fMRI result of the right hemispherectomy patient with left foot movement activation.



Conclusion
Locomotor therapy such as BWST can improve motor connectivity in hemispherectomy patients. Further study is needed to optimize motor functions of the residual corticospinal pathway and long term follow-up assessment with fMRI will be helpful in the future research.

Reproducibility of Metrics Derived from Diffusion Tractography in a Cohort of Pediatric Patients

Paldino, M. J.·Rodrigues, K. M.·Hedges, K.·Grant, P. E.
Children's Hospital Boston
Boston, MA.

Purpose
The reproducibility of parameters derived from diffusion tractography has not been widely studied and, in particular, there is very little data from the developing brain. The goal of this study is to quantify the test-retest repeatability of ADC and FA derived from tractography in a cohort of pediatric patients.
Materials & Methods
Patients were identified retrospectively from a database of pediatric epilepsy patients who met the criteria of having 1) a 3T brain MR examination and 2) Two separate but identical DTI sequences obtained in the same MR session. Patients were excluded for seizure during the examination or significant degradation to image quality such as by motion. Diffusion Toolkit was used for deterministic tract reconstruction(angular threshold: 35 deg). Two users experienced in tractography performed tract segmentation and analysis in Trackvis (www.trackvis.org). Tracts segmented included the corpus callosum as well as bilateral corticospinal tracts, inferior longitudinal fasciculi, inferior fronto-occipital fasciculi, and arcuate fasciculi (AF). Mean ADC and mean FA were calculated for each tract. For each patient, the two individual diffusion datasets were analyzed independently by different users, resulting in two observations for each parameter for every tract. Prior to considering the entire dataset in toto, the mean difference between observations across the following subgroups was compared using the Wilcoxon signed-rank test: 1. Tracts from structurally normal versus dysplastic brains; 2. Left- versus right-sided tracts. 3. Each tract versus the remaining aggregate of all other tracts (e.g., all corticospinal tracts versus all other tracts). Any potential difference between observations from the two users also was assessed using the Wilcoxon signed-rank test. For each parameter, we then calculated: 1. Mean coefficient of variation (CoV). 2. Regression coefficient; 3. Repeatability coefficient; 4. Ninety-five percent confidence limits (95%CL) for change. For any tracts not identified bilaterally in all patients, Cohen's kappa coefficient was calculated to assess agreement between the readers.
Results
Twenty patients were included (age range: 3-18 years). All tracts were identified bilaterally in all patients except for the AF, which was not identified on the right in eight subjects and not identified on the left in five subjects. Repeatability was consistent across the dataset; hence, the remaining tests were performed based on all identifiable tracts. No difference between observations was identified($p = 0.89$). Test-retest estimates of the reproducibility of mean ADC and mean FA are presented in Table 1. For the AF, Cohen's kappa coefficient for agreement between the readers (absent vs present) was 1.0 [95%CI (1.0, 1.0)].

Repeatability of mean ADC and mean FA derived from DTI tractography. Asterisk (*): $p < 0.01$.

	ADC	FA
mean CoV (%)	2.8	2.5
Regression Coefficient	0.952*	0.964*
Repeatability Coefficient	0.00015	0.014
95% CL for change (%)	10.3	8.6

Conclusion
These findings demonstrate good test-retest repeatability of mean ADC and FA derived from DTI tractography in a cohort of pediatric patients. Change greater than the repeatability coefficient or 95%CL for change are unlikely to be related to intrinsic variability of the method.

Neuroimaging Abnormalities Are Prevalent in Adolescents with Lupus at Time of Disease Quiescence

Hunter, J. V.·Canter, D. L.·Muscal, E.
Texas Children's Hospital
Houston, TX.

Purpose
Conventional neuroimaging abnormalities have been described in children and adults with active neuropsychiatric lupus (NPSLE). We hypothesized similar findings in children with inactive neurologic disease.
Materials & Methods
We acquired conventional MRI sequences on a 3T scanner as part of a prospective neuropsychology and novel neuroimaging study. A pediatric neuroradiologist (JVH) assessed white matter lesions and measures of parenchymal volume loss on conventional anatomical sequences while blinded to disease status.
Results
Imaging was acquired for N = 41 right-handed adolescents (mean age 15.6 $\pm$ 1.6 years; female 90%; Hispanic 41% and African-American 24%). Mean disease duration at time of imaging was 29.1 $\pm$ 26.7 months. Only five subjects (12.2%) had a history of NPSLE. Disease activity indices reflected well controlled and inactive disease for all subjects at the time of imaging. Most subjects were on prednisone (92.7%, mean dose 19.1 $\pm$ 12.0 mg) and 41.4% were on

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

additional immunosuppressive agents (methotrexate, mycophenolate mofetil, or azathioprine) at imaging. Many of the adolscents had positive vasculopathy markers (39.0% with a lupus anticoagulant and 65.9% with a positive antiphospholipid antibody). T2 or FLAIR sequences revealed 18 subjects (43.9%) with small (2-3 mm) multifocal punctate white matter (WM) lesions. There were no gray matter lesions visualized. All subjects with WM lesions had at least one frontal lesion (50% with bifrontal lesions). Additional locations of WM lesions included parietal lobes (16.6%) and centrum semi-ovale (11.1%). Corpus colossal thinning was observed in 22.0% of subjects. Features suggestive of cerebral volume loss were common (sulcal widening 65.6% and ventricular dilation 34.1%). Cerebellar volume loss (foli prominence) was observed in 68.3% of subjects. Evidence of WM lesions or parenchymal volume loss was not associated with previous nephritis, hypertension, vasculopathy risk factor positivity, or cumulative prednisone dosing. Measurements of Evan's ratio, thickness of the corpus callosum and size of third ventricle were not associated with cumulative prednisone dosing. Measures of executive function were not significantly lower in adolescents with abnormal MRIs.
Conclusion
We observed a predominance of frontal WM lesions and parenchymal volume loss in a large percentage of adolescents with lupus. Conventional MR imaging abnormalities were documented early in disease courses and at times of disease inactivity. Evidence of nervous system involvement on advanced imaging may indeed predate clinical manifestations in adolescent lupus patients. These abnormalities appeared to be independent of corticosteroid burden and may reflect subclinical neuroinflammation or vascular disease in this population.

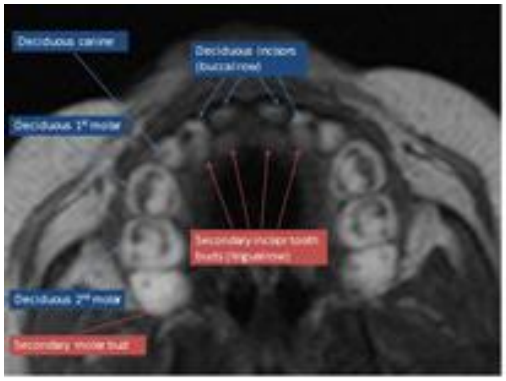
MR Anatomy of Developing Teeth in the Neonatal Period

Whitehead, M. T.·Choudhri, A.
University of Tennessee/Lebonheur Children's Hospital Memphis, TN.

Purpose
Odontogenesis is a complex process that initiates in the embryonic period and continues into adulthood. Primary and secondary teeth formation begin at six and 20 gestational weeks, respectively. Normal term neonates have 20 developing unereupted primary teeth. To our knowledge, there is no existing literature regarding normal MR imaging patterns of teeth in term neonates. Pathologic diagnoses require familiarity of normal anatomy. In this article, we will review the normal tooth embryology and anatomy and detail the normal MR appearance of developing neonatal teeth.
Materials & Methods
Fifty-nine consecutive neonatal patients' brain MRIs (ages 0 to 27 days) were reviewed by two pediatric neuroradiologists boarded by the ABR with CAQs in neuroradiology. Seven premature patients (<37 weeks gestation) and two patients with inadequate field of view were excluded. Mandibular and maxillary tooth anatomy was detailed on T1, T2, T2 FLAIR, and postcontrast T1-weighted images (when available) from the remaining 50 patients' MRIs.
Results
The imaging pattern of developing teeth in the neonate is remarkably consistent. In all patients, the primary teeth were in the early maturation stage with several distinct MRI regions. Hypointense surfaces represent the developing crowns partially envelope neural crest mesenchyma that will become the dentin, pulp, and periodontia. Permanent teeth anlagen were present in some locations along the lingual aspect of deciduous teeth. Medial incisor and lateral incisor permanent teeth in the bell stage of development were present in all patients bilaterally in the mandible and maxilla. Permanent teeth bells representing early developing molars resided posterior to the developing deciduous mandibular and maxillary teeth in all patients. The majority of patients (36/50) also had visible permanent bilateral maxilla and mandibular canine teeth buds.



Conclusion
The developing primary and secondary unerupted teeth display characteristic MR appearances in normal neonates. Twenty developing primary teeth in the maturational stage are consistently present. Several unmineralized tooth bells of secondary teeth also are present.

eP-248

Healthy Preterm Infants Have a Preserved Hemodynamic Response to Transient Elevation of Intracranial Pressure during Anterior Fontanelle Compression

Zamora, C. A.·Tekes, A.·Alqahtani, E.·Northington, F. J.·Kalayci, O.·Huisman, T. A. G. M.
Johns Hopkins University School of Medicine
Baltimore, MD.

Purpose
Abnormal cerebral autoregulation plays a major role in the development of a variety of neonatal neurologic complications. Particularly, the preterm infant is presumed to have abnormal autoregulation, although the available evidence is conflicting and not conclusive. We performed this study 1- to determine normative cerebral resistive index (RI) values in healthy preterm and term infants and 2- to establish whether or not the hemodynamic response to transient elevation in intracranial pressure during anterior fontanelle compression is different between these groups.
Materials & Methods
This retrospective study included healthy preterm and term infants less than three months of age with a normal first head ultrasound (US). Resistive indexes were measured in the anterior cerebral circulation at the beginning of the study, first at baseline and then following three-five seconds of fontanellar compression with the transducer. Patients were excluded on the basis of sepsis, hypoxic ischemic encephalopathy, subsequent intracranial adverse events, intracranial procedures, cardiac surgery, clinically significant cardiac shunts, cardiomyopathies, or congenital cardiac malformations. We calculated normal baseline values and ranges (mean ± two standard deviations) and percent change in RI between baseline and compression. Two-tailed unpaired t tests were utilized to separately compare mean baseline RI, mean compression RI, and mean percent change in RI between the two groups.
Results
A total of 129 healthy subjects were included in the study. Gestational age ranged from 25 to 41 weeks. Mean follow up (± standard deviation) was 200 ± 175 days. Mean baseline RI was 0.7 ± 0.08 in preterm (n = 67; normal range, 0.54 - 0.86) and 0.66 ± 0.07 in term infants (n = 62; normal range 0.52 - 0.8). This difference in mean RIs was statistically significant (P = .001). Mean RI during fontanellar compression was 0.71 ± 0.08 in preterm and 0.68 ± 0.07 in term infants. This difference in mean RIs was also statistically significant (P = .015). The mean percent change in RI between baseline and compression was 5.86% ± 4.2% in preterm and 7.47% ± 6.2% in term infants. This difference was not statistically significant (P = .092).
Conclusion
There was no difference in the hemodynamic response to fontanelle compression (as measured by percent change in RI from baseline) between healthy preterm and term infants. This suggests that cerebral autoregulation is preserved in the healthy preterm infant. In addition, we present the normative baseline and compression RI values for both groups in a large group of healthy term and preterm infants.

Systematic Radiologic Phenotyping and Decision Tree Analysis of Multiparametric MR Imaging Data in Pediatric Posterior Fossa Tumors

Kamaly-Asl, I.[1,2]·Cain, J.[1]·Gledson, A.[1]·Tang, V.[2]·Wright, N.[2]·Soh, C.[3]·Birch, J.[1]·Keane, J.[1]·Jackson, A.[1]·Stivaros, S. M.[1,2]
[1]University of Manchester, Manchester, UNITED KINGDOM, [2]Royal Manchester Children's Hospital, Manchester, UNITED KINGDOM, [3]Salford Royal Foundation NHS Trust, Manchester, UNITED KINGDOM.

Purpose
Imaging remains crucial to diagnosis, staging and treatment planning in pediatric posterior fossa tumors. Despite recent advances in multiparametric MRI techniques there still remains significant uncertainty in the radiologic phenotyping of a proportion of these tumors. In addition, specific histologic diagnosis and grading often guides surgical resection but is not always available pre/intraoperatively. We have developed a systematic reproducible descriptive imaging model that integrates advanced quantitative MRI imaging metrics into one data repository. This dataset underpins a radiologic decision support system (DSS) that facilitates more accurate radiologic phenotyping of these tumors.
Materials & Methods
Using the North West Children's Tumour Registry we collated available imaging, demographic and histological data on 115 pediatric patients presenting with posterior fossa tumors from 1953 to April 2012. A language-based systematic analysis and scoring system was devised to model the imaging phenotype with correlation to proven histology of these development cases. Computerized decision tree analysis of the imaging database was performed using multiple algorithms to derive an imaging phenotype classification system which could be used as a diagnostic DSS. The imaging of 40 patients with posterior fossa tumors presenting to our institution between January 2008 and January 2012 then was selected randomly and independently reported by one general neuroradiologist, two pediatric radiologists with an interest in pediatric neuroradiology and one dedicated pediatric neuroradiologist. Using the DSS the same cases were re-reported at a later date and a comparison made between the radiologic diagnostic accuracy with and without the systematic reporting schema and DSS.
Results

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

The median patient age used to create the radiologic phenotype model was 7.2 years with a range of 2.6 - 15.3 years, of whom 49% were female. The descriptive model contained 30 major attributes which accommodated 120 variables giving just under one million variable permutations per patient. The most successful decision tree algorithm for diagnostic stratification was found to be Alternating Decision (AD) Tree with a true positive rate of 93% and an ROC area of 98%. The initial radiologic diagnostic accuracy varied between 68 - 75%. In the patients with disconcordant radiologic and histologic diagnoses four pilocytic astrocytomas were felt to be cystic ependymomas/medulloblastoma. Two medulloblastomas were felt to more closely resemble ependymomas. Two brainstem gliomas were found to be noncystic pilocytic astrocytomas. One atypical teratoid rhabdoid tumor was radiologically characterized as an ependymoma and two ependymomas were incorrectly called medulloblastoma/pilocytic astrocytoma. By contrast, repeat imaging analysis using the systematic schema in combination with the ADTree DSS yielded a diagnostic accuracy of 93%.

Conclusion

To our knowledge this study is the first systematic descriptive model of pediatric posterior fossa tumors integrating any radiologic metric. It validates the concept of decision tree analysis for diagnostic prediction using systematic phenotypic modelling and demonstrates the potential of an automated decision tree classification DSS. Validation will require the analysis of larger numbers of scans from patients with posterior fossa tumors of known and unknown etiology. We think this work points towards such techniques having a huge potential as diagnostic tools.

Pediatric Pilocytic and Pilomyxoid Astrocytomas: MR Imaging Characteristics and a Comparison of Apparent Diffusion Coefficient and T2/Cerebrospinal Fluid Measurements

Lindsay, A. J.·Rush, S. Z.·Fenton, L. Z.·Stence, N. V.
Children's Hospital Colorado
Denver, CO.

Purpose

Pilocytic astrocytomas (PCAs) are the most common primary brain tumor in children. Pilomyxoid astrocytomas (PMAs) are a variant of PCAs that are characterized by a higher rate of recurrence and CSF dissemination. Imaging findings overlap in these tumors. MR diffusion-weighted imaging correlates with water diffusivity and cellularity and differs for some tumors, thus serving as a potential discriminatory tool . Our goal was to review MR imaging characteristics of PCAs and PMAs and compare quantitative apparent diffusion coefficient (ADC) and T2-weighted signal metrics for differences to facilitate distinguishing these tumors.

Materials & Methods

Following IRB approval, the neuro-oncology database at a tertiary care Children's Hospital was reviewed retrospectively for patients with pathology proven PCA and PMA from 2003 to 2012. Patients with neurofibromatosis I were excluded. Eleven patients with PCA and nine patients with PMA were identified. On MRI at presentation, tumor characteristics were recorded and regions of interest (ROIs) were drawn within solid tumor on T2-weighted images and ADC maps. Regions of interest were drawn within ventricular CSF to normalize the T2-weighted data and to provide a similar ratio for the ADC data. The mean T2/CSF, ADC, and ADC/CSF and minimum ADC values were recorded. A delta ADC value was recorded by obtaining the maximum difference of five ADC values within different areas of solid tumor. Tumor volume was measured by drawing ROIs around the solid portion of the tumor using TeraRecon.

Results

Results are summarized in Tables 1 and 2. Pilocytic astrocytomas patients were older (median age 5.4 years) than PMA patients (median 1.9 years). No PMAs were predominantly cystic, while 3/11 PCAs were predominantly cystic. PMAs more frequently homogeneously enhanced (78% versuss 27%) and were more frequently homogeneously T2 hyperintense (78% versus 18%). Excluding patients without an adequate follow-up interval, PMAs were more likely to become cystic with time (71% versus 30%). Mean T2/CSF, mean ADC, mean ADC/CSF, minimum ADC, delta ADC, and tumor volume were greater for PMAs than PCAs, though the differences were not statistically significant.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Table 1: Demographics and Qualitative Results

		PCA (11 Patients)	PMA (9 Patients)	p value (* for < 0.05)
Age		6 months to 18 years (median 5.4 years)	3 months to 5 years (median 1.9 years)	0.028*
Gender		7 male (64%)	3 male (33%)	0.178
Tumor Location				
-	Optic Pathway	6 (55%)	6 (67%)	0.582
-	Posterior Fossa	5 (45%)	2 (22%)	0.279
-	Other	0	1 (11%)	0.257
Tumor Characteristics				
-	Solid	6 (55%)	5 (56%)	0.964
-	Cystic	3 (27%)	0	0.08
-	Mixed	2 (18%)	4 (44%)	0.202
-	Infiltrative	4 (36%)	5 (56%)	0.39
Enhancement				
-	Homogeneous	3 (27%)	7 (78%)	0.025*
-	Heterogeneous	8 (73%)	2 (22%)	0.025*
T2 Hyperintensity				
-	Homogeneous	2 (18%)	7 (78%)	0.008*
-	Heterogeneous	9 (82%)	2 (22%)	0.008*
Treatment		3/10 (30%)	5/7 (71%)	0.092

Table 2: Quantitative Results

	PCA (11 Patients)	PMA (9 Patients)	p value
Mean T2/CSF	0.656	0.767	0.16
Mean ADC [10(-6) mm2/sec]	1316	1394	0.64
Mean ADC/CSF [10(-6) mm2/sec]	0.447	0.464	0.78
Mean Minimum ADC [10(-6) mm2/sec]	1200	1280	0.72
Mean Delta ADC [10(-6) mm2/sec]	195.7	253.7	0.29
Mean Tumor Volume [mL]	27.64	36.04	0.5

Conclusion

Relative to PCAs, at diagnosis PMAs are less frequently cystic, and more often homogeneously T2 hyperintense and enhancing. Pilomyxoid astrocytomas were more likely than PCAs to become cystic with treatment over time. Although mean T2/CSF, mean ADC, mean ADC/CSF, minimum ADC, delta ADC, and tumor volume were greater for PMAs than PCAs, the differences were not statistically significant and could not reliably distinguish PMA from PCA.

Low Grade Gliomas: Neuroimaging Findings of Pseudoprogression after Radiotherapy

Naftel, R.·Zuccoli, G.·Deutsch, M.·Jakacki, R.·Pollack, I. F.
Children's Hospital of Pittsburgh
Pittsburgh, PA.

Purpose
Increasing enhancement and mass effect following radiation therapy in patients with low-grade gliomas (LGG) can be mistaken for tumor progression and/or malignant degeneration. Differentiating this “pseudoprogression” from true progression is necessary to determine the need for alternative therapy. This study investigates the incidence, timetable, and changes in size of low-grade glioma after radiotherapy.
Materials & Methods
Retrospective chart review was performed on children treated with radiotherapy (RT) for LGG at the Children’s Hospital of Pittsburgh Neuro-Oncology program with at least one year of followup. A blinded neuroradiologist performed tumor measurements using the largest cross-sectional area.
Results
Twenty-nine children, median age 12, underwent RT (external beam-23, gamma knife-6) for tumor recurrence (2/29) progression (10/29), or as a primary treatment (14/29). Histologies included juvenile pilocytic astrocytoma (20/29), LGG (5/29), and radiologic diagnosis of LGG (4/29). Sixteen patients developed increased enhancement and/or mass effect following RT with a median time to maximum tumor enlargement of six months, with a range of four months up to 4.2 years. Twelve patients reached their peak size within eight months while four patients did not reach their peak until after 2.7 years. The pseudoprogression tumor size enlarged to a median maximum cross-sectional area of 154.9% of the pre-RT baseline. The pseudoprogression tumor size decreased to a median stable cross-sectional area of 72.8% of the pre-RT baseline. In comparison, all patients without pseudoprogression experienced decrease in size of the tumor and stabilization. The tumor size decreased to a median stable cross-sectional area of 15.3% of the pre-RT baseline. Ten children were symptomatic

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

and treated with steroids (n = 10) and/or avastin (n = 3). Three children were operated upon, two for cyst fenestration, and one for debulking after concern for true progression; however, pathology showed treatment effect: radiation necrosis with scattered juvenile pilocytic astrocytoma tumor cells. In all 16 cases, the tumor eventually decreased in size without additional antitumor therapy. With a median followup of 4.8 years (range 1.0-12.4 years), all patients remain alive and only one patient experienced true progression.

Conclusion

Tumor pseudoprogression was seen in over half of patients with LGG. Most patients experienced pseudoprogression in the first eight months after RT; however, four patients experienced maximum pseudoprogression after 2.7 years. While both pseudoprogression and nonpseudoprogression patients experienced stability of their tumors, at the last followup pseudoprogression tumors were still on average larger than those without pseudoprogression.

MR Imaging of Pleomorphic Xanthoastrocytomas in Children with Emphasis on Diffusion-Weighted Imaging

Moore, W.[1]·Mathis, D.[1]·Gargan, L.[2]·Klesse, L.[1]·Margraf, L.[1]·Bowers, D. C.[1]·Koral, K.[1,2]
[1]University of Texas Southwestern Medical Center at Dallas, Dallas, TX, [2]Children's Medical Center, Dallas, TX.

Purpose

To describe the imaging characteristics of pediatric pleomorphic xanthoastrocytoma (PXA) with particular attention paid to diffusion-weighted imaging characteristics.

Materials & Methods

Review of Neuro-Oncology database revealed 11 PXAs from 1/1998 through 4/2012. The pathology specimens were reviewed and diagnoses were confirmed according to the 2007 WHO Classification of Central Nervous System Tumors. Two patients did not have preoperative imaging performed at our institution. Remaining nine patients had preoperative MRI and seven had DWI performed with b values of 0 and 1000. The examinations were reviewed by a fourth-year radiology resident and a pediatric neuroradiologist. The location, size, signal and enhancement characteristics, presence of cyst(s), presence and size of the perilesional edema were recorded. On the ADC maps, the solid components of the tumors were sampled by placing as many as nonoverlapping region of interests (ROIs). One ROI was placed on the normal thalamus. Mean tumor ADC values and tumor: normal brain ADC ratios were calculated.

Results

Of the nine patients, two had anaplastic features. Eight tumors were supratentorial. The supratentorial tumor volumes varied from 1.73 cm^3 to 249.86 cm^3 (mean = 98.61, SD = 103.58). Six of the eight supratentorial tumors were associated with scalloping of the inner table. Six lesions had either multiple cysts or predominantly cystic. Seven of the nine patients had significant vasogenic edema about the solid tumor, defined as greater than 10 mm in diameter. Except for the smallest tumor in the temporal lobe, all tumors showed intense heterogenous enhancement. Tumor ADC values could be measured reliably in six patients. The ADC mean was 874 ± 214 x 10^{-6} mm^2/s (min-max: 617-1189). The tumor: normal brain ADC ratio was 1.12 ± 0.28 (min-max: 0.75-1.32).

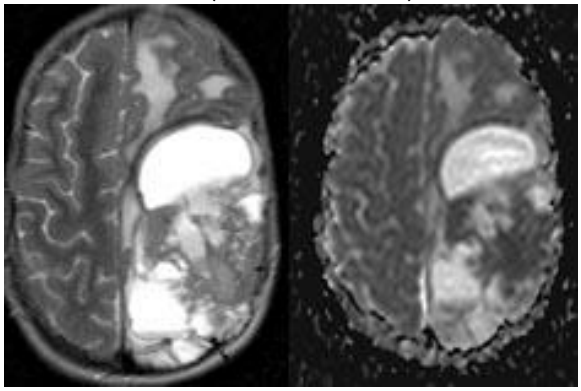

Figure: Axial T2-weighted and axial ADC map of a six-year-old male with pleomorphic xanthoastrocytoma.

Conclusion

Pleomorphic xanthoastrocytoma is a rare tumor of pediatric central nervous system. It can attain a relatively big size in the cerebral hemispheres until becoming symptomatic and its diffusion characteristics may be confused with aggressive tumors.

KEYWORDS: Pediatric neoplasms, Pleomorphic xanthoastrocytoma

MR Diffusion and Perfusion Characteristics of Desmoplastic Infantile Ganglioglioma

Barad, U. H.·Ho, C. Y.·Kralik, S. F.
Indiana University
Indianapolis, IN.

Purpose

MR imaging using diffusion and perfusion has been used previously to differentiate low-grade and high-grade brain tumors; however, diffusion and perfusion imaging characteristic of desmoplastic infantile ganglioglioma (DIG) has not been described previously in the literature to our knowledge.

Materials & Methods

Two cases of DIG were diagnosed at our institute between October 2009 and March 2011. In addition to routine pre and postcontrast sequences including diffusion-weighted

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

imaging, dynamic T2* perfusion images were performed on 1.5T superconducting Avanto (Siemens, Erlangen, Germany) with TR 1531 msec TE 30.6 msec, slice thickness of 5 mm and rate of injection 4 ml/sec.
Results
On perfusion images, the solid enhancing portion of tumor demonstrate rCBV equivalent to contralateral white matter and cystic areas has no increase in rCBV as expected. Diffusion appearance on ADC map of the solid enhancing portion is equivalent of the gray matter.
Conclusion
Brain tumor presenting within the first two year of life may be large in size and have a heterogeneous appearance on MRI. The use of advance MR imaging techniques including diffusion and perfusion imaging helpful to diagnose DIG, a low-grade tumor, from high-grade PNET or ATRT. Because complete surgical resection considered curative, preoperative surgical diagnosis is essential for favorable outcome.

MR Imaging in a Young Child without Removal of the Cochlear Implant Magnet: Technical Aspects

Jacob, R.[1,2]·Roland, P.[1,2]·Morriss, M.[1,2]
[1]Children's Medical Center, Dallas, TX, [2]University of Texas Southwestern Medical Center, Dallas, TX.

Purpose
Cochlear implants (CI) are used widely for treatment of sensorineural hearing loss. Over 30,000 children in USA have received cochlear implants. Traditionally if a patient with a CI needs an MRI, it necessitates surgical removal of the CI magnet and post-MRI surgical replacement of the magnet. In recent years MR has been performed safely in a limited number of adults and older children without removal of the CI magnet. This case describes the technical aspects and planning behind the performance of an MR study on a three-year seven-month-old child without removal of the CI magnet. This is the first report of a child this young undergoing such a procedure.
Materials & Methods
The patient required MR imaging of the brain to evaluate for leukodystrophy. He had previously undergone implantation of a Med El CI on the right. At the request of the child's parent and in consultation with the pediatric otologist, pediatric neuroradiologist - MRI safety officer, a decision was made to perform the MRI study without removal of the CI magnet. A preprocedure CT was performed to evaluate thickness of the bone well around the magnet. Informed consent was obtained from the parent. A mold was created by the otolaryngology department with hearing aid molding material to cover the scalp overlying the CI magnet. Gauze was tightly wound around the head to hold the mold in place over the magnet. The study was performed under general anesthesia. The patient was carefully moved in and out of the magnet bore under supervision of the MRI safety officer. MR imaging of brain was performed on a Philips 1.5T magnet. Low specific absorption rate axial T2, axial FLAIR and sagittal T1 sequences were obtained.
Results
The patient tolerated the study with no evidence of local heating, pain or malfunction of the CI. Clinical examination confirmed no dislocation of the magnet. The images were felt to be diagnostic. Artifacts from the CI were demonstrated in the right parietal, temporal and occipital lobes and lateral aspect of right cerebellar hemisphere. This corresponded to approximately 18% of the brain area at the level of the third ventricle. No artifacts were demonstrated in the bilateral internal auditory canal regions. The artifacts were of similar size on all sequences.
Conclusion
MR imaging on a young child with a CI was performed safely on a 1.5T magnet without removal of the cochlear implant magnet. This case describes the strict technical and safety measures to be followed. The study was of diagnostic quality with the artifact from the implant limited to a small portion of the brain.

eP-255

Quantitative Analysis of Cortical Thickness in Children Treated with Craniospinal Radiation versus Posterior Fossa Conformal Radiation Therapy

Stence, N. V.[1]·Plimpton, S. R.[2]·Mirsky, D. M.[1]·Foreman, N. K.[1]·Liu, A.[2]
[1]Children's Hospital Colorado, Aurora, CO, [2]University of Colorado Denver, Aurora, CO.

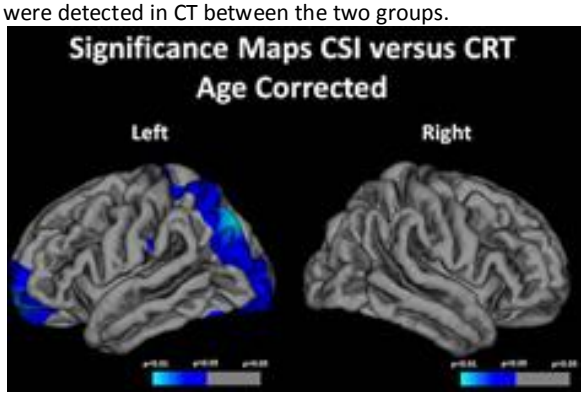
Purpose
Standard therapy for different posterior fossa tumors can include either craniospinal radiation (CSI) or conformal radiation therapy (CRT). Children who receive radiation therapy as part of treatment for posterior fossa tumors are known to experience long-term neurocognitive delays. Evidence suggests neurocognitive function may be relatively preserved in children treated with CRT versus CSI. Other recent research has attempted to correlate cortical thickness (CT) with measures of intelligence in patients with schizophrenia and in normal controls. In general, there is a positive correlation between CT and IQ. However, CT in various regions of the brain do change rapidly during childhood and adolescence, and the way CT changes over time is influenced by IQ. This study sought to determine if CT in children treated with CSI was measurably different than children treated with posterior fossa CRT.
Materials & Methods
Seventy-nine patients who received radiation therapy for

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

the treatment of a brain tumor were included in the analysis. Fifty-one received CSI as standard therapy for their tumor (medulloblastoma, PNET, and nongerminomatous germ cell tumor). Twenty-eight received focal posterior fossa CRT for ependymoma. Analysis included MRI performed after completion of radiation therapy for tumor surveillance. Routine scanning included a noncontrast T1 MPRAGE sequence with isotropic 1 mm voxel size. Reconstruction of the cortical surfaces and measurement of cortical thickness were performed using the FreeSurfer toolkit (version 5.1). Cortical surfaces were reconstructed and parcellated. Patient surfaces were resampled onto an "average brain" for significance mapping. A general linear model was used in FreeSurfer via the QDEC toolbox for statistical analysis. Significance maps were smoothed with a 25 mm kernel. Differences between CSI and CRT were corrected to ignore age in model fitting (age was treated as a nuisance). ANCOVA was used to determine p-values for each CSI versus CRT lobe.

Results

Mean range of follow-up for CSI patients was 38.1 months, and for CRT patients was 23.3 months. Cortical thickness in CSI patients was significantly thinner in the left parietal and left occipital lobes ($p<0.001$), and trended towards significantly thinner in the left frontal lobe ($p<0.108$) (Figure 1). No other statistically significant differences were detected in CT between the two groups.



Conclusion

Cortical thickness in children treated with CSI was thinner in the left parietal and occipital lobes compared to children treated with CRT. Further research is needed to correlate CT differences with differences in specific neurocognitive outcomes in these two groups.

Are We Imaging Gently?: Radiation Dose to Children Undergoing Head and Cervical Spine CT at Nonpediatric Hospitals

Burgin, K.·Ramakrishnaiah, R. H.·Kumar, M.·Samant, R.·Shilpa, H.·Van Hemert, R.·Glasier, C. M.·Angtuaco, E.
University of Arkansas for Medical Sciences
Little Rock, AR.

Purpose

Children sustaining trauma are more likely to undergo head and cervical spine CT study at the nearest hospital which is likely a nonpediatric, adult hospital. The purpose of this study is to compare CT parameter and radiation dose to children undergoing CT studies of head and cervical spine at adult hospitals with the parameters and radiation dose at a dedicated tertiary care pediatric hospital.

Materials & Methods

This is a retrospective study at a tertiary care pediatric hospital and a tertiary care university hospital. Head and cervical spine trauma workup CT studies of children with ages between one day to 15 years that are imported via the emergency medical service (EMS) from various adult hospitals across the country to the PACs of a tertiary care pediatric hospital and a university hospital will be selected. Patients will be grouped under three age-specific groups (Group A: one day to five years, Group B: five years to 10 years and Group C: 10 years to 15 years). Ten head CT and 10 cervical spine CT studies will be included under each age group. Exact age-matched groups will be replicated with CT studies of head and cervical spine performed at the tertiary care pediatric hospital with optimized CT parameters compliant with American College of Radiology CT accreditation program requirements. All CT studies will be quality checked and nondiagnostic scans will be excluded from the study. The CT parameters (kVp and mAs), CTDI and DLP will be collected from the dose page of the CT studies. The corrected dose in mSv will be derived using recommended correction factor for patient weight and body size. Statistical analysis for added radiation dose and the significance will be determined.

Results

We expect a significantly higher radiation dose received by pediatric patients undergoing CT studies of head and cervical spine at nonpediatric hospitals without CT technique optimization.

Conclusion

This study emphasizes the role of the radiologist to establish strict protocols in both the pediatric and adult hospital setting to reduce radiation exposure to children.

Abnormal Findings on Brain MR Imaging in Neurologically Normal Children: Classification Scheme and Process for Reporting and Clinical Followup in a Research Study of Normal Brain Development

Leach, J. L.·Vannest, J.·Schapiro, M.·Holland, S.
Cincinnati Children's Hospital Medical Center
Cincinnati, OH.

Purpose
To describe the MRI findings in normal children recruited for an imaging study of normal development, and define a standardized classification and clinical follow-up process for these studies.
Materials & Methods
MR imaging from 114 subjects recruited for a study of normal brain development (Pediatric Functional Imaging Research Network, NICHD - HHSN275200900018C) formed the study group. Subjects and first degree relatives had a negative history for neurologic or psychiatric disease. Subjects were in normal school classes, reached normal developmental milestones, had no history of head trauma, GA < 37 or >42 weeks, BW >10th percentile, no chronic illness, and normal neurologic examinations. MR imaging was performed at 3T with 1mm isotropic T1-weighted and T2 FLAIR sequences. Imaging evaluation was performed by a board-certified pediatric neuroradiologist with 20 years' experience interpreting pediatric brain imaging. Imaging studies were classified as: 0-normal, 1- normal variant, 2 - possibly clinically significant, 3 - likely clinically significant, 4- cannot interpret (artifact). Studies also were assessed for alteration of normal anatomy (potentially important for grouped normative data) and need for clinical followup. A standardized procedure for image evaluation, reporting, and followup will be presented.
Results
There were 47 males and 67 females in the study group with a mean age of 8.3 years (2 months - 18 years). One hundred twelve studies were evaluated (two were uninterpretable - motion artifact). Fourteen (12.5%) had findings of possible (12) or likely (2) clinical significance. Clinical followup was recommended in 13 (11.7%). Six (5.4%) had distortion of normal anatomy that could impact group morphologic analyses. Likely clinically significant abnormalities included a small 4th ventricular mass, and extensive sinus disease with an obstructive antral choanal polyp. Possibly clinically significant abnormalities included: White matter abnormalities - six, Tonsillar ectopia - two, Callosal anomalies - two, Paranasal sinus opacification - two, Encephalomalacia - one.
Conclusion
Abnormalities were identified in 12.5% of normal children in a research study of normal brain development using MRI. Most required clinical or imaging followup. Six findings (43% of abnormal studies) involved the white matter, which may be difficult or impossible to detect on standard volumetric T1-weighted sequences. Performance of high-resolution FLAIR sequences in the research setting may demonstrate more potential brain pathology. Identified abnormalities may be clinically important and can impact utilization for normative studies. A well defined classification, reporting, and follow-up process is strongly recommended when imaging children in the research setting.

Can Transcranial Doppler Ultrasound Predict Patient Stay?

Aw, J.·Burrowes, D.·Schoeneman, S. E.·Smith, C. M.·Wainwright, M. S.
Ann & Robert H Lurie Children Hospital of Chicago
Chicago, IL.

Purpose
Transcranial Doppler ultrasound (TCD) is a portable, noninvasive examination assessing measurements of cerebral blood flow velocities, from which the Resistive Index (RI) & Pulsatility Index (PI) can be calculated. The use of TCD has been used primarily with the Stroke Prevention Trial in Sickle Cell Anemia. The value of TCD also has been investigated in the setting of subarachnoid hemorrhage and occlusive carotid and vertebral artery disease. Its use in other indications has not been defined completely, particularly with respect to the value of resistive and pulsatility indices. The purpose of this study is to review the TCD RI and PI in acutely ill patients treated in the pediatric intensive care unit (PICU). The RI and PI were reviewed to determine if there are any statistical correlations between these indices and the patient's hospital stay.
Materials & Methods
IRB approval was obtained. Our limited TCD protocol includes the interrogation of the proximal, middle and distal segments of the middle cerebral artery (MCA). All patients who had undergone a limited TCD between June 1, 2010 and September 19, 2012 were identified on our PAC system. The standard deviations for the average RI and PI for each patient's MCA were correlated with hospital stay using the Pearson's test.
Results
There were 39 patients out of a total of 216 who had multiple TCD exams while in the ICU. Preliminary review of four out of 39 patients, who had multiple TCD's ranging from 4 - 8 TCD exams. The hospital stay in these patients ranged from 12 - 42 days. A strong positive correlation was found with the standard deviation for RI and hospital stay (Right RI r = 0.8, Left RI r = 0.4), a moderate positive correlation with the left PI (r = 0.2) and a moderate negative correlation with the right PI (r = -0.2).
Conclusion
Transcranial Doppler ultrasound has been a proven benefit

in the sickle cell, subarachnoid hemorrhage and occlusive carotid and vertebral artery disease patients. The preliminary data suggest the greater the standard deviation of the RI, the longer the patient remained in the hospital. The higher standard deviation could suggest greater clinical instability and in turn reflect the number of days the patient remained in the hospital. These preliminary data suggest that more work is required in this area to determine a standard deviation that may indicate clinical instability.

eP-259

High-Resolution MR Imaging Evaluation of Obstetric Brachial Plexus Injury: A Promising Alternative to Traditional CT Myelography

Somashekar, D. K.·Parmar, H.·Ibrahim, M.·Yang, L.
University of Michigan
Ann Arbor, MI.

Purpose
Despite recent improvement in perinatal care, the incidence of obstetric brachial plexus injury (OBPI) is still up to three per 1000 births. Obstetric brachial plexus injuries vary from complete nerve disruption at the level of the brachial plexus (neurotmesis), or nerve root avuslions at the spinal cord level to milder form including neuropraxia (nerve stretching) and axonetmesis (disruption of axon sheath). Clinically it is difficult to characterize the lesion type, as patients may present with similar apparent deficiencies. CT myelography (CTM) currently is considered as the best imaging modality for evaluating nerve root avulsion, and continues to be the most widely practiced technique. Recent improvements in MRI techniques have made MRI an attractive alternative to evaluate nerve root avulsions. Our aim was to demonstrate utility of the novel MRI technique in evaluation of normal spinal nerve roots and in avulsion injuries of these roots.
Materials & Methods
Institutional review board approval was obtained and patient consent waived for this HIPAA-compliant, prospective study. All patients with clinically diagnosed OBPI and who underwent MRI between July 2011 and December 2012 were identified. MR imaging was performed using a high-resolution heavily T2-weighted T2 DRIVE sequence with 0.6 mm slice thickness and using uniform voxel size. MR imaging findings were reviewed by two board-certified neuroradiologists by consensus to document presence of any nerve root avulsion from C5 to T1 and for presence of pseudomeningocele. The operative findings of those patients that went to surgery were reviewed. The surgical findings were compared to the pre-operative MR diagnoses and the comparisons were labeled as either concordant or discordant.
Results
There were 13 patients (nine male, four female) with clinically diagnosed brachial plexus abnormality. Six out of 13 patients went on to surgery during which a total of 19 nerve roots were evaluated. A total of eight avulsions were found at surgery and in 11 other patient the injury was more distal (rupture). Six out of eight avulsions identified at surgery were at C5-6 level, consistent with existing surgical literature, while one nerve root avulsion was identified at C7 and C8 level respectively. The overall sensitivity and specificity of MRI for nerve root avulsion was 75% and 82% respectively. Interestingly, in two patients who had surgically positive nerve root avulsion but negative MRI had no pseudomeningocele at those levels.
Conclusion
Our preliminary results show that high-resolution MRI offers an excellent alternative to CTM in the evaluation of brachial plexus avulsion injuries with similar sensitivity compared to that of CTM. Unlike conventional CTM it is noninvasive and does not use ionizing radiation. Further refinement of the technique and validation of our findings in larger patient population will go a long way in making this as the primary imaging modality for evaluation of OBPIs.

Age-Related Changes of the “Eye-of-the-Tiger“ Sign in MR Imaging

Stoeter, P.·Vilchez, C.·Roa, P.·Speckter, H.·Perez-Then, E.·Oviedo, J.
CEDIMAT
Santo Domingo, DOMINICAN REPUBLIC.

Purpose
To describe and quantify changes of the “eye-of-the-tiger” sign with increasing age in patients with pantothene-kinase associated neurodegeneration (PKAN), and to look for an imaging parameter which might be related to the progression of the disease.
Materials & Methods
Included were the MR data from 30 patients (four to 76 years old) and three genetically positive cases (seven to 11 years old) without clinical manifestation, all with a confirmed mutation of the PKAN2 gene. Evaluation was based mainly on T2-, T2*, diffusion- and T1-weighted scans including measurement of the extension of the hypointense part of the “tiger’s eye”.
Results
The youngest (4-year-old) patient presented with a hyperintensity in the globus pallidus in T2-weighted images, but without reduction of diffusion, and only the T2* sequences showed a tiny signal drop below this area. Whereas this patient was already symptomatic, the three “preclinical” cases presented the classical “tiger’s eye”. Six

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

older patients, however, did not show the typical bright spot. The extent of the hypointense area was significantly ($p<0.01$) correlated to age, but not to the degree of dystonia ($p>0.05$). The maximum of signal loss was localized in the area below the "tiger's eye", corresponding exactly to a severe and circumscribed hypointensity in T1-weighted images in eight patients. Otherwise, the globus pallidus was diffusely hyperintense in T1-weighted except from the "tiger's eye". This area was iso- or slightly hypointense in T1-weighted sequences, but in four cases, it was seen as a bright spot in both T1- and T2-weighted imaging.

Conclusion

The changes of the "eye-of-the-tiger" sign with increasing age correspond well to the current hypotheses of an early lesion turning into an area of gliosis, and an accumulation of iron in the globus pallidus which starts below this lesion and increases over time. Its varying appearance in different MR sequences can be explained by the susceptibility effects of this paramagnetic substance. However, some questions about the preference of the lesion and the accumulation of iron to affect two different areas in the anterior part of the globus pallidus, and about the latency between the acute stage and the clinical manifestation remain open. Because the extent of the iron accumulation is not significantly correlated to the degree of dystonia, we cannot recommend use of it as a parameter for disease progression.

Arachnoid Cysts and Intracranial Arteriopathy as Hallmarks of Neural Crest Involvement in Tuberous Sclerosis

Boronat, S.·Thiele, E.·Johnson, J.·Caruso, P.
Massachusetts General Hospital
Boston, MA.

Purpose

Some clinical findings in tuberous sclerosis complex (TSC), such as hypomelanotic macules are related to maldevelopment of the neural crest (NC), which is also the origin of the cranial meninges and some of the intracranial vessels. The purpose of this study is to evaluate the frequency and characteristics of menigeal involvement and intracranial arteriopathy in TSC in a large cohort of patients and to review the pertinent literature.

Materials & Methods

We reviewed the brain MRIs of 220 patients with definite clinical diagnosis of TSC for arachnoid cysts, meningiomas, and intracranial arterial anomalies of neural crest origin. We then reviewed the literature with regard to these findings.

Results

Features of intracranial arteriopathy on MRI were detected in four of 220 (1.8%) patients with TSC higher than the frequency found on studies of incidental MRI findings in the normal asymptomatic population (0.5%,0.21% to 0.87%). The internal carotid artery (ICA) was the most frequently affected. 5.6% of patients (12 out of 220) had arachnoid cysts (ACs) higher than the prevalence found on MRI in asymptomatic individuals (0.35%, 0.13% to 0.67%). Three patients showed two or more ACs and two of these patients had associated autosomal dominant polycystic disease (ADPKD), which also predisposes to ACs and is also known to be associated with an increased risk for intracranial aneursyms. One patient had a meningioma. One patient presented with a clinical diagnosis of TSC, no intracranial tubers or subependymal nodules (SENs) on imaging, but showed an intracranial AC, a phenotype that we propose as the neural crest-specific phenotype of TSC. Arterial aneurysms, mostly aortic and intracranial, have been reported as a rare finding in TSC and two cases of arachnoid cysts (ACs) and two cases of meningiomas have been reported to date in TSC; however, the literature contains to date only case reports of these neural crest-related manifestations, and our study represents the only large systematic review.

Conclusion

Neural crest (NC) related pathology presents with a higher frequency in TSC than in the general population. Meninges, intracranial smooth vascular cells (SMCs), and pericytes of the forebrain are of NC origin. Arachnoid cysts and intracranial arteriopathy are part of the clinical spectrum of TSC and may be present in patients with the NC-specific phenotype.

eP-262

Diffusion Tensor Imaging of the Pediatric Thoracic Spinal Cord Using a Short Echo Time Inner Field-of-View Sequence

Middleton, D. M.[1]·Mohamed, F. B.[1]·Barakat, N.[2]·Finsterbusch, J.[3]·Faro, S. H.[1]·Shah, P.[1]·Samdani, A.[2]·Mulcahey, M.[2]
[1]Temple University, Philadelphia, PA, [2]Shriners Hospital for Children, Philadelphia, PA, [3]University Medical Center Hamburg-Eppendorf, Hamburg, GERMANY.

Purpose

Studies of the cervical spinal cord (SC) in subjects with spinal cord injury (SCI) have shown good correlation between DTI values and clinical examination results. Extending this technique to the thoracic SC is challenging due to physiologic motion which is more prevalent in the thoracic region. In the cervical SC, use of an inner field-of-view (iFOV) sequence has been shown effective in producing good quality images. The purpose of this study was to implement and evaluate the iFOV DTI sequence for imaging of the pediatric thoracic SC in normal and injured subjects.

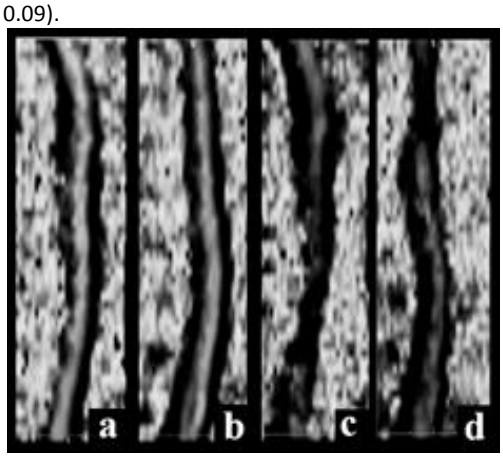
Materials & Methods

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Eight pediatric subjects, six typically developing (TD) subjects without evidence of SC pathology and two patients with SCI were recruited. Imaging was performed using a short echo iFOV echo-planar DTI sequence. This sequence was implemented on a 3.0T Siemens Verio MR scanner and optimized for imaging the thoracic SC. Images were acquired axially along the SC. Sequence parameters used were: 20 directions, b = 1000s/mm^2, voxel size = 1.2x1.2x3 mm^3, slices=50, TR=7400 ms, TE=89 ms, averages=3. Due to length of the thoracic SC, imaging was split into two slabs with acquisition time was approximately seven minutes per slab. Motion correction was applied and tensor estimation was performed on the corrected images. Regions of interest (ROIs) were drawn on each axial slice along the length of the thoracic SC in the center of the cord to minimize averaging of the SC with surrounding cerebrospinal fluid (CSF). Values for fractional anisotropy (FA), mean diffusivity (MD), axial diffusivity (AD), and radial diffusivity were calculated for each ROI.

Results

Images were acquired successfully using the iFOV sequence. Midline sagittal images reconstructed from axial slices showed good cord/CSF delineation in both TD subjects (Figure 1a:T1-T8,1b:T7-L1) and subjects with SCI (Figure 1c:T1-T10,1d:T7-L2). Mean indices for TD subjects were FA = 0.42 ± 0.05, MD = 0.52 ± 0.09, AD = 0.75 ± 0.09, RD = 0.40 ± 0.05. Subjects with SCI showed decreases in FA and increases in diffusivity indices (mean values FA = 0.24 ± 0.04, MD = 0.63 ± 0.10, AD = 0.79 ± 0.10, RD = 0.56 ± 0.09).



Conclusion

The iFOV sequence used was effective in acquiring DTI images of the pediatric TSC with less distortion. Subjects with SCI exhibited decreased FA and increased diffusivity indices when compared to TD subjects. These results are extremely promising and warrant data collection in a large group of subjects.

Match Day: Online Search Trends Reflect Real-Time Interest in Neuroradiology Training

Harsha, A.·Schmitt, J.·Mohan, S.
University of Pennsylvania
Philadelphia, PA.

Purpose

Internet search trends have been shown to parallel the growth of consumer interest in products and services across many industries. The purpose of this study is to identify and characterize temporal relationships between the growth in the neuroradiology fellowship applicant pool and related internet search engine queries.

Materials & Methods

From July 1, 2006 to July 1, 2011, the Google Trends tool was used to analyze search engine query data for "neuroradiology fellowship" and related terms to identify individuals seeking information regarding fellowship training. These terms returned a search volume index (SVI) representing the search frequency relative to the total search volume during the study interval and geographic region for the United States during each academic year. Results were compared with National Residency Match Panel Specialties Matching Services (NRMP-SMS) match data using a Pearson correlation analysis. Regression analysis was employed to characterize annual search trends and peak search activity.

Results

Normalized mean annual search traffic for neuroradiology fellowship increased by 46% over the 60-month study period. There was an annual mean SVI increase of 10% (range 7 - 32%; SD 17%), with a linear increase in yearly SVI over time. There was a similar increase in total neuroradiology fellowship applicants (57% increase) over

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

the study interval. Annual SVI approached statistical significance in predicting the total number of applicants for that match year (R_2= 0.71, p = 0.17). Additionally, there were statistically significant differences in SVI by month (p = 0.041) with greatest increase in mean SVI observed in December (52% increase; range 16 - 69%; SD 22%).
Conclusion
There has been an overall increase in internet search traffic related to neuroradiology fellowship with a correlation to the annual growth in total number of fellowship applicants. Reflected in this trend is an annual peak in search traffic in December corresponding to the NRMP application cycle. In-depth analysis of internet search queries mirror real-time trends in radiology trainee professional interests and may provide useful information for fellowship directors to attract potential candidates.

Acute TeleStroke Management and Therapy System Using Mobile Phone and Tablet

Takao, H.[1]·Murayama, Y.[1]·Ishibashi, T.[1]·Karagiozov, K. L.[1]·Vinuela, F.[2]
[1]The Jikei University School of Medicine, Tokyo, JAPAN, [2]University of California Los Angeles, Los Angeles, CA.

Purpose
Physicians must quickly evaluate acute stroke patients to determine treatment. Prompt diagnosis and treatment of cerebral stroke patients are essential for their recovery. With the increasing demands for management of stroke, shortening the time of decision making through telemedicine is becoming important. Based on this hypothesis, we developed a telestroke system in Japan (called “Synapse ERm”) for faster access to diagnostic images and clinical information.
Materials & Methods
This system is based on transferring patient data, images, movies (Angio and/or operating room), and face-to-face meeting between hospital systems and participating medical staffs in and out of the hospital, using their standard, currently utilized mobile devices (iPhone, Andorid) and Tablet. The system is able to transfer clinical data, CT, MR, echo, angiographic and intraoperative images and expert opinion in real time like Facebook and Twitter. It also provides tools for management of diagnosis and treatment information, for example, simple calculation of appropriate drug dosage, modified Rankin Scale and perfusion diffusion mismatch.
Results
A pilot application of the system in our hospital showed adequate performance and proper information transfer, resulting in proper diagnosis and management of all stroke patients. This system was installed at our institution in August 2010, for communication with our affiliated hospitals. Over 161 stroke calls were initiated until the end of July 2012.

Conclusion
The telestroke system proved to be efficient for appropriate standard management in most time-demanding treatments of stroke. It is our belief that utilization of this system with handheld devices will make it possible to help and save the lives of more stroke patients.

KEYWORDS: Teleradiology, Structural network, telestroke

eP-265

Reports and Studies of Uncommon Conditions with Critical Intracranial Imaging Findings Are More Frequently Published in the Nonradiology Compared to the Radiology Literature

Doolittle, D.·Lehman, V. T.·Schwartz, K.·Eckel, L.
Mayo Graduate School of Medical Education
Rochester, MN.

Purpose
Imaging findings of CNS disease are reported both in the peer-reviewed radiology and in the clinical literature. Given changes in radiology journal preferences, we hypothesize that recent primary reports and studies of imaging features of several uncommon diseases with intracranial manifestations are more frequent in the nonradiology literature.
Materials & Methods
PubMed searches from 12/1/2007-12/1/2012 were performed for four uncommon CNS diseases with intracranial imaging manifestations using the following search terms: 1.) ‘Susac Syndrome OR Susac’s Syndrome’ 2.) ‘(transient lesion OR reversible lesion) AND corpus callosum’ 3.) ‘amyloid beta related angiitis OR ABRA OR amyloid vasculitis’ and 4.) ‘Parry Romberg Syndrome OR en coup de sabre’. Included case reports or series contained figures and text of imaging features; included original research contained, at minimum, descriptions of imaging findings of included patients. Exclusion criteria

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

were: 1.) Non-English language, 2.) Review article and 3.) Non-target diagnosis captured by search terms. Articles were characterized as case reports, case series or original research. Original research was categorized as containing either: 1) Only description of imaging findings of study patients or 2) Specific assessment of an imaging technique or systematically studied imaging features of the disease were noted. Journals were categorized as radiology or nonradiology.

Results

One hundred twenty-one articles (95 case reports, 15 case series, and 11 original research) met inclusion criteria, 30 for Susac's Syndrome, 53 for transient lesion of the corpus callosum, 13 for amyloid beta related angiitis (ABRA), and 25 for Parry Romberg Syndrome. One hundred five articles were derived from nonradiology journals; 16 from radiology journals. Eight original research articles specifically assessed imaging techniques or imaging features, all eight in nonradiology journals. Two original research articles assessed imaging features of ABRA including leptomeningeal enhancement, one assessed mass-like lesions with ABRA, one characterized the intracranial imaging findings in Parry-Romberg Syndrome, two assessed diffusion tensor imaging findings with Susac's Syndrome, one assessed rate of lesions in the corpus callosum and rate of contrast enhancement with Susac's Syndrome, and one compared the appearance of Susac's lesions to multiple sclerosis lesions at 7T.

Conclusion

Reports and studies of the selected uncommon diseases with intracranial manifestations are far more frequent in clinical journals when compared to dedicated radiology publications. A substantial proportion of uncommon disease imaging findings are in the form of case reports, which frequently are published in nonradiology journals. Radiologists should review both radiology and nonradiology journals when searching for reports of imaging features of uncommon diseases affecting the brain. Radiologists should consider further study of these diseases with publications within the radiology literature.

KEYWORDS: Susac's syndrome, Amyloid, radiology literature

eP-266

Are NIH-Funded Articles Cited More? A Study of the American Journal of Neuroradiology

Davis, M. A.·Castillo, M.·Henderson, L.
University of North Carolina-Chapel Hill
Durham, NC.

Purpose

We evaluated whether or not funding through the National Institutes of Health (NIH) has any bearing on the citation counts of published works. We looked at papers published in the American Journal of Neuroradiology (AJNR) and hypothesize that papers without NIH funding are cited just as much as those with NIH funding.

Materials & Methods

Through the Thomson Reuters database "Web of Knowledge" we accessed all articles published in AJNR from 1997- 2007 using specific filters and keywords. Data then were filtered for NIH and non-NIH-funded studies. NIH funded AJNR publications also were accessed through the Research Portfolio Online Reporting Tools (RePORT) powered through the NIH. The number of citations per article was extracted from the "Web of Knowledge" database. We identified the total number of citations per article and per year, to date, and extracted these data into total AJNR publications, AJNR publications funded through NIH, and AJNR publications not funded through NIH. We defined a publication as having NIH funding if it was stated in the authors notes as having funding through the NIH or if the publication was stated as funded under the RePORT database. Only original, full-length, research articles were used. Using the raw data a t-test for significance was performed.

Results

A total of 3761 original research articles were published in the AJNR between 1997 and 2007. Of this number 169 articles were funded through NIH. NIH-funded articles showed an average of 32.79 citations per article with an average of 2.03 citations per year. Non-NIH-funded articles received an average of 24.74 citations per article and an average of 1.51 citations per year. NIH-funded publications comprised 6% of all citations for AJNR publications. These findings were statistically significant with p =.001.

Conclusion

In AJNR, NIH-funded publications were cited more often than those that were not funded.

KEYWORDS: AJNR, citations

eP-267

Moving Forward: Lessons Learned from a Multiphase Practice Quality Improvement Initiative Aimed at Addressing Appropriate Utilization of Screening CT in the Emergency Department

Griffith, B.·Vallee, P.·Krupp, S.·Jung, M.·Slezak, M.·Nagarwala, J.·Loeckner, C. P.·Jain, R.
Henry Ford Hospital
Detroit, MI.

Purpose

The purpose of this project is to discuss the lessons learned over the course of our multiphase practice quality improvement (PQI) initiative aimed at improving utilization of screening cervical spine CT in the emergency department. The project will address issues related specifically to improvements in appropriate utilization of cervical spine CT, as well as general issues of project development, implementation, and analysis as they relate to addressing appropriate utilization of all imaging.

Materials & Methods

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Despite the availability of screening criteria for cervical spine imaging [National Emergency X-Radiography Utilization Study (NEXUS) and Canadian Cervical Spine Rule (CCR)], many patients continue to be imaged without meeting these criteria. The goal of this multiphase PQI initiative was to assess appropriate utilization of screening cervical spine CT in the emergency department following blunt trauma and whether educating clinicians regarding these criteria could improve over-utilization rates. The study was designed in three phases: Phase 1 was a retrospective evaluation of all cervical spine CT examinations performed following blunt trauma. Phase 2 was a collaborative prospective study between the Departments of Radiology and Emergency Medicine, assessing utilization following introduction of an ordering clinician survey. Phase 3 was reassessment of utilization following implementation of an education initiative. Each phase evaluated appropriate utilization according to the NEXUS criteria with emphasis on the ACR Appropriateness Criteria in Phases 2 and 3. This exhibit will discuss the design, implementation, and results of the project's three phases, exploring potential reasons for "over-utilization", as well as methods for improving appropriate use of imaging. The exhibit also will discuss PQI requirements related to maintenance of certification (MOC) and provide a guide to implementing similar PQI projects at other institutions.

Results

Of 1524 patients without injury evaluated during Phase 1, 23.9% had no documentation of any of the five NEXUS low-risk criteria and therefore were potentially unnecessary examinations. Following introduction of an ordering clinician survey documenting study indication, the rate of "over-utilization" decreased to 16.1% in Phase 2. This rate further decreased to 13% following implementation of a clinical education program. The findings of our multiphase PQI project show that despite availability of screening tools for cervical spine imaging, many patients continue to be imaged without meeting these criteria. The findings also show that simply educating ordering clinicians regarding appropriate criteria is effective in decreasing unnecessary studies and improving patient care. Applying the methods used in this multiphase approach to utilization of other imaging studies has potential to significantly impact patient care across the healthcare spectrum.

Conclusion

The lessons learned from this study have important implications not only for radiology, but for the future of healthcare across the country. With limited resources and more patients, there is emphasis on appropriate utilization of all healthcare resources, with much attention directed towards medical imaging. Therefore, it is incumbent upon radiologists to take the lead in addressing appropriate use of all imaging studies. This project lays out an achievable method of assessing and improving appropriate utilization of imaging while also fulfilling maintenance of certification requirements.

Discrepancies between Gender and Use of Brain MR Imaging: Analysis of Indications, Pathology, and Interventions

Lau, D.·Bentley, J. N.·Maher, C. O.·Shah, G. V.
University of Michigan Health System
Ann Arbor, MI.

Purpose

Ever since the use of magnetic resonance imaging (MRI), female patients tend to undergo more brain MRIs than males; the reason for this and its consequences remain unclear. In this study, we identified the most common indications and assess the indication differences between female and male. We also evaluate whether certain indications are more likely associated with pathology and/or interventions between males and females.

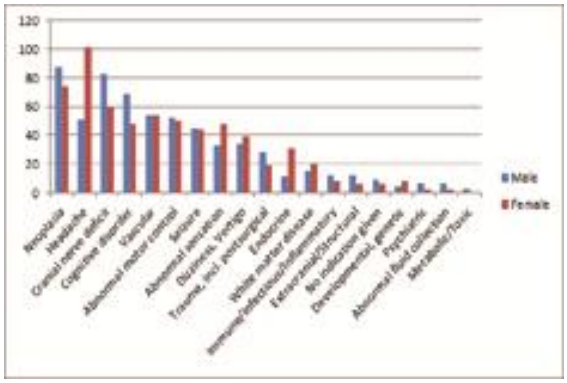
Materials & Methods

All brain MRIs from 1997 to 2009 were identified. Analysis for differences in frequency and number of brain MRIs between genders was performed. Next, 100 male and 100 female MRIs were randomly selected in seven age groups. Repeat MRIs and patients aged less than 18 were excluded. Data regarding indication, pathology, need for neurology and/or neurosurgery consultation, and intervention/surgery were collected. Descriptive statistics and chi-squared test were employed to assess outcome differences between genders by age and specific indications.

Results

A total of 48,417 brain MRIs were performed: 20,327 males and 28,090 females. Males underwent greater numbers of MRIs in patients 18 years and younger. But from 19 years and on, females underwent more MRIs; there were peaks in the third and eighth decade. After randomized selection, 1,236 patients remained. The three most common indications for brain MRI were neoplasia, headache, and cranial nerve deficit. When stratified by indications, males underwent significantly more MRIs than females for cranial nerve deficit (13.5% vs. 9.7%, $p=0.037$) and cognitive disorders (11.2% vs. 7.7%, $p=0.038$). Females underwent significantly more MRIs than males for headache (8.2% vs. 16.3%, $p<0.001$) and endocrine disorders (1.8% vs. 5.0%, $p=0.002$). However, among these four indications, there were no significant differences in pathology, consultation, and interventions between males and females. Rather males underwent significantly more neurosurgical interventions for an indication of neoplasia (28.7% vs. 12.2%, $p=0.010$), and males had significantly higher rates of major pathology for an indication of vascular concern (63.0% vs. 42.6%, $p=0.034$).

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Conclusion

During childhood and adolescent ages, males tend to undergo more brain MRI studies, but after the first two decades females undergo more brain MRIs. The higher incidence of headaches possibly explains the higher rates and numbers of brain MRI; however, there is no difference in presence of pathology, need for consultation, and intervention. Rather a suspicion/indication for neoplasia in males was associated with higher rates of need for neurosurgical intervention. Decisive use of brain MRI is warranted, especially for patients with headache and without neurologic deficits.

Effect of Adaptive Statistical Iterative Reconstruction on Patient Dose in Neuroradiology Computed Tomographic Studies

Komlosi, P.·Zhang, Y.·Ornan, D.·Wintermark, M.
University of Virginia
Charlottesville, VA.

Purpose

Adaptive statistical iterative reconstruction (ASIR) is a signal processing method that can decrease image noise, thereby computed tomographic (CT) images of comparable diagnostic quality can be obtained using less radiation. The purpose of this study is to quantify the effect of systematic use of ASIR versus filtered back projection (FBP) for neuroradiology CT protocols on patients' radiation dose and image quality.

Materials & Methods

This retrospective, HIPAA-compliant study was approved by our institutional review board, with waiver of informed consent. We evaluated the effect of ASIR on six types of neuroradiologic CT studies: unenhanced brain CT in adult patients, unenhanced brain CT in pediatric patients, adult cervical spine CT, adult cervical and intracranial CT angiography, adult soft tissue neck CT with contrast, and adult lumbar spine CT. For each type of CT study, two series of 100 consecutive studies were reviewed: 100 studies performed with FBP and 100 studies performed with ASIR of 40%. Dose modulation was systematically used, with appropriate noise indices for FBP and ASIR. For each examination, the weighted volume CT dose index (CTDIvol) and dose-length product (DLP) were recorded and noise was measured. Each study also was reviewed for image quality by a board-certified neuroradiologist, and noise was measured as the standard deviation of the CT density in the patient's background. Continuous variables (CTDIvol, DLP, noise) were compared by using t-tests, and categorical variables (image quality) were compared by using Wilcoxon rank-sum tests.

Results

For adult cervical and intracranial CT angiograms, the CTDIvol and DLP, respectively, were reduced by 28.5% and 21.6%, respectively, by using ASIR versus FBP. Significant dose reductions ($P < .001$) also were observed for adult unenhanced brain CT and lumbar CT studies performed with ASIR. Analysis is ongoing for pediatric unenhanced, neck soft tissue and cervical spine CT studies, and complete results will be presented at the ASNR meeting. Image quality and noise were similar for both FBP and ASIR.

Conclusion

Use of advanced statistical iterative reconstruction for neuroradiology CT examinations affords significant dose reduction while maintaining image quality.

KEYWORDS: Dose reduction, CT, ASIR

Prevalence of Subsequent Intracranial Neoplasms on Screening MR Imaging in Long-Term Survivors of Childhood Acute Lymphoblastic Leukemia

Sabin, N. D.·Santucci, A.·Klimo, P.·Zhang, N.·Srivastava, D.·Pui, C.·Hudson, M. M.·Krull, K. R.·Kun, L.·Krasin, M.·Reddick, W. E.·Hillenbrand, C.·Ogg, R.·Patay, Z.·Robison, L. L.·Armstrong, G. T.
St. Jude Children's Research Hospital
Memphis, TN.

Purpose

To determine the prevalence of intracranial neoplasms on screening magnetic resonance imaging (MRI) in a group of long-term survivors of childhood acute lymphoblastic leukemia (ALL) who presented with no overt neurologic complaints.

Materials & Methods

One hundred sixty-four long-term survivors of childhood ALL [including 125 treated with cranial radiation therapy (CRT)] underwent unenhanced screening MRI examination of the brain as part of a larger study of neurocognitive outcomes. The median age at the time of the study was 30.8 years (range 19-51 years) and the median time from diagnosis of ALL was 25.5 years (12-46 years). MRI examinations were reviewed by a single neuroradiologist. Demographic and treatment data were compared for survivors with and without subsequent neoplasms.

Results

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Eighteen of 164 survivors (11%) had a total of 30 subsequent intracranial or craniocervical junction neoplasms. All survivors who had a subsequent neoplasm had received CRT. Development of intracranial neoplasm was associated with CRT exposure (p=0.0076) but not with sex, race/ethnicity, age at diagnosis or chemotherapy exposure. Among the 125 patients who had received CRT, 18 (14.4%) developed subsequent tumors and 14 (78%) of those received CRT doses ≥ 20 Gy. All patients with subsequent neoplasms were greater than 20 years from their primary cancer diagnosis. Six patients had multiple tumors. All but two subsequent neoplasms were supratentorial. Notably, all patients presented with no overt neurologic complaints. Three tumors (17%) involved the superior sagittal sinus. A single craniocervical junction neoplasm displaced and deformed the upper cervical spinal cord. By noncontrast MRI, the neoplasms were most suggestive of meningiomas. Six tumors were resected. By histopathology, four of these were WHO grade 1 meningiomas, one was a WHO grade 2 atypical meningioma and one was a meningioma with unspecified grade. One lesion was treated with gamma knife radiotherapy without biopsy or resection. The remaining patients are being followed with serial imaging.

Conclusion

Adult survivors of childhood ALL who received CRT are at long-term risk of developing intracranial or craniocervical junction neoplasms and the prevalence of these neoplasms increases with length of time from primary cancer diagnosis. We detected a higher percentage of intracranial neoplasms in survivors treated with cranial RT than in earlier reports of such neoplasms in ALL survivors up to 20 years post-therapy. As all of our survivors with neoplasms were greater than 20 years post-diagnosis, this likely reflects the long latency period for the development of meningiomas resulting in increased detection over time. In addition, the prevalence may be underestimated since the MRI examinations for this series were obtained without intravenous contrast. The patients in our study presented with no overt neurologic complaints despite the fact that some tumors demonstrated significant mass effect or involved the superior sagittal sinus suggesting the need for periodic screening with brain MRI of long-term survivors of childhood ALL who received CRT.

KEYWORDS: Radiation effects, Leukemia, subsequent neoplasms

eP-271

Initial Utilization of a New MR Acute Stroke Protocol

Kubal, W. S.·Meshksar, A.·Nael, K.
University of Arizona
Tucson, AZ.

Purpose

We recently introduced a new MR acute stroke protocol in our institution. Following educational presentations and introduction of the new protocol into clinical practice, we noted a dramatic increase in utilization. We were concerned that the new procedure might be over utilized due to supplier-induced demand. Supplier-induced demand may occur when asymmetry of information exists between the supplier and the consumer particularly with the introduction of a new product or service. The purpose of this study is to compare utilization and incidence of positive results of the new protocol with the old protocol.

Materials & Methods

The former acute stroke protocol took approximately 20 minutes of imaging time. The new stroke protocol takes only approximately 10 minutes of imaging time. The time saving was largely achieved by replacing the time-of-flight MRA with a comprehensive contrast-enhanced MRA. The diffusion-weighted sequence in each protocol is comparable. The accuracy and efficiency of the new protocol has been reported previously. Forty-three consecutive patients underwent the old acute stroke protocol MR imaging between June 01 and August 30 and 156 consecutive patients underwent the new acute stroke protocol MR imaging between September 10 and December 9. An experienced neuroradiologist reviewed all patients. Inclusion criteria were history of an acute neurologic deficit and successful completion of the exam. The final groups consisted of 38 patients in the old protocol group and 141 patients in the new protocol group.

Results

The increase in utilization over a comparable time period was both dramatic and highly statistically significant. A positive result was defined as restricted diffusion compatible with acute infarct. In the old protocol group 10/38 = 26% and in the new protocol group 32/141 = 23% showed a positive result. These data were analyzed with a z-test for uncorrelated samples and $z = 6.88$, $p < 0.001$. This result is highly significant for the same incidence of positive results in each group despite a great increase in utilization.

Conclusion

The rapid growth of medical technology has provided physicians with an increased ability to diagnose abnormalities and treat patients. New technologies are strongly advocated and may become widely used without careful assessment of their appropriate role in the care of patients. When there is an asymmetry of information, there is potential for an artificial increase in demand. We were concerned that a new protocol we introduced for diagnosis and characterization of acute stroke might be over utilized. We found that although utilization had increased dramatically, the incidence of positive results was statistically unchanged both before and after introduction of the new scan protocol. We speculate that the increase in patients being scanned reflects adoption of the new protocol over less comprehensive imaging algorithms. Due to the shortened imaging time of the new protocol, there was a lower resource cost for each positive diagnosis.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eP-272

Limited Headache Imaging Using an Axial FLAIR Pulse Sequence

Besachio, D. A.·Abele, T. A.·Davidson, H.·Quigley, E.·Rassner, U.
University of Utah
Salt Lake City, UT.

Purpose
Neuroimaging often is performed in the setting of non-acute, non-focal headache. Studies have shown that in the setting of non-acute headache magnetic resonance (MR) imaging demonstrates clinically significant findings in only 0.6-1.5% of cases. The fluid-attenuated inversion recovery (FLAIR) sequence has proven useful in evaluation of a broad array of intracranial pathologies and thus may be useful as a screening sequence for the evaluation of nonacute headache. The purpose of this study is to determine the feasibility of limited brain MR imaging using a single noncontrast axial FLAIR sequence to screen patients with nonacute, nonfocal headache.
Materials & Methods
A radiology information system search was performed for history of "headache" in brain MR imaging from May through November 2012. Subjects with an acute presentation, a history of malignancy, seizure, demyelinating disease or specifically stated focal neurologic findings were excluded. Imaging orders requested with a disease specific MRI protocol (e.g., multiple sclerosis protocol) also were excluded. A neuroradiologist with a certificate of added qualification blinded to the results of the complete MR scan independently reviewed the single axial FLAIR sequence of each study. The examiner was asked to identify abnormalities, indicate whether further examination was felt to be necessary, and why further imaging was needed. Findings from the single axial FLAIR sequence were compared to those from the full MR scan to assess the utility of FLAIR imaging as a screening sequence.
Results
A preliminary data set of 50 subjects was identified meeting inclusion criteria. Patient ages were 18-80 years (mean 41 years). Based on the single axial FLAIR sequence, the neuroradiologist requested additional imaging in 15 of 50 subjects. Based on the full examination, eight subjects had a finding that could explain their headache or had nonheadache-related findings requiring further evaluation (Table 1). All eight of these subjects were identified correctly in the 15 subjects for which additional imaging was requested. Sensitivity and specificity of the single axial FLAIR sequence for identification of a possible source of headache or other nonheadache-related finding requiring followup was 100% and 81%, respectively.

Findings in data set with (*) indicating a potential headache source or other important finding.

Intracranial pathology	Number	%
Nonspecific white matter disease	20	40
Normal	19	38
Anatomical variant	4	8
Chiari 1*	3	6
Neoplasm*	2	4
Demyelinating disease*	2	4
Parenchymal hemorrhage*	1	2

Conclusion
A single axial FLAIR sequence interpreted by a neuroradiologist may be adequate to screen patients with nonfocal, nonacute headache.

eP-263

Practical MR Imaging Grading System for Cervical Foraminal Stenosis Based on Oblique Sagittal Images

Park, H. J.
Sungkyunkwan University School of Medicine, Kangbuk Samsung Hospital
Seoul, KOREA, REPUBLIC OF.

Purpose
To propose a new and practical MRI grading method for cervical neural foraminal stenosis and to evaluate its reproducibility.
Materials & Methods
We evaluated 50 patients (M:F = 37:13, mean 49 years) who visited our institution and underwent oblique sagittal MRI of the cervical spine. A total of 300 foramina and corresponding nerve roots in 50 patients were analyzed qualitatively from C4-5 to C6-7. We assessed the grade of cervical foraminal stenosis at the maximal narrowing point according to the new grading system based on T2-weighted oblique sagittal images. The incidence of each of the neural foraminal stenosis grades according to cervical level was analyzed by chi-square tests. Intra and interobserver agreements between two radiologists were analyzed using kappa statistics. Kappa value interpretations were poor ($k < 0.1$), slight ($0.1 \leq k \leq 0.2$), fair ($0.2 < k \leq 0.4$), moderate ($0.4 < k \leq 0.6$), substantial ($0.6 < k \leq 0.8$), and almost perfect ($0.8 < k \leq 1$).
Results
Significant stenoses (grades 2 and 3) were rarely found at the C4-5 level. The incidence of grade 3 at the C5-6 level was higher than at other levels, a difference that was statistically significant. The overall intraobserver agreement according to cervical level was almost perfect. The agreement at each level was almost perfect, except for only substantial agreement at the right C6-7 by reader 2. No statistically significant differences were seen according to cervical level. Overall kappa values of interobserver agreement according to cervical level were almost perfect. In addition, the agreement of each level was almost perfect. Overall intra and interobserver agreement for the presence of foraminal stenosis (grade 0 vs. grades 1, 2, and 3) and for significant stenosis (grades 0 and 1 vs. grades 2 and 3) showed similar results and were almost perfect. However, only substantial agreement was seen in the right C6-7.
Conclusion
A new grading system for cervical foraminal stenosis based on oblique sagittal MRI provides a reliable assessment and good reproducibility. This new grading system is a useful and easy method for the objective evaluation of cervical neural foraminal stenosis by radiologists and clinicians.

eP-274

Clinical Correlation of a New Practical MR Imaging Method for Assessing Central Lumbar Spinal Stenosis

Park, H. J.
Sungkyunkwan University School of Medicine, Kangbuk Samsung Hospital
Seoul, KOREA, REPUBLIC OF.

Purpose
To evaluate interobserver agreement and determine whether a new MRI grading system agrees with symptoms and neurologic signs.
Materials & Methods
We examined 160 patients (M:F = 72:88; mean age, 65 years) who underwent MRI of the lumbar spine at our institution and were evaluated by two musculoskeletal radiologists. The presence and grade of central lumbar spinal stenosis (CLSS) at L3-4, L4-5 and L5-S1 were assessed according to a new grading system, the Lee system. The results were correlated with clinical manifestations and neurologic examinations [positive neurologic manifestation (PNM), negative neurologic manifestation (NNM)]. Statistical analyses were performed using kappa statistics, and nonparametric correlation analysis (Spearman's correlation).
Results
Interobserver agreement in the grading of CLSS between the two readers was substantial (k value = 0.780). Interobserver agreement of the L4-5 level and older age group were high (0.789, 0.814). The correlation coefficient (R) of reader 1 between MRI grade (0, 1, 2, or 3) and neurologic manifestations (negative or positive) was 0.654; the R of reader 2 was 0.591. In the younger age group (<57 years), the R of reader 1 was 0.634 and the R of reader 2 was 0.500. In the older age group (≥ 57 years), the R of reader 1 was 0.650 and the R of reader 2 was 0.645. Correlation coefficients were higher at the level of L3-4 (0.612 - 0.678) than other levels but did not show statistical significance ($p > 0.05$).
Conclusion
Interobserver agreement for the new CLSS grading system was substantial. Grade 0 was associated with NNMs and grade 3 with PNMs in this cohort. Grade 2 demonstrates more cases of PNM than NNM but requires further evaluation. Correlations between MRI grade and clinical manifestations were moderate and slightly higher in older patients.

Utility of CT-Guided Bone Biopsy for Vertebral Osteomyelitis

Bauml, J. A.·Bosman, S. A.·Hansra, N.·Saran, N.
University of Illinois at Chicago Medical Center
Chicago, IL.

Purpose
CT-guided bone biopsy has been advocated as a useful tool to aid in the diagnosis and treatment of suspected vertebral osteomyelitis. No large review study providing convincing evidence supporting this practice is available. This single institution retrospective study is aimed at providing concrete data to help guide the discussion and debate over the usefulness of image-guided bone biopsy for vertebral osteomyelitis.
Materials & Methods
Data pertaining to vertebral body bone biopsies performed from January 2003 to March 2011 at the University of Illinois Hospital Chicago was compiled. Antibiotic regimens/treatment plans (prebiopsy) for the patients undergoing biopsy were recorded. Alterations in treatment plan based on the results of these biopsies were analyzed. The study design was that of a retrospective chart review.
Results
Of the 109 total vertebral body biopsies performed during the study period, 72 were performed for clinically or radiologically suspected cases of vertebral osteomyelitis. Fifty of these patients with clinically diagnosed osteomyelitis had negative culture results. Of the patients with negative culture results, the biopsy changed management in one case, but that change was based on unexpected pathology rather than culture results. In seven patients the biopsies never yielded a diagnostic culture. The total number of positive culture results from these 72 biopsies was 15. Two of those patients were lost to followup. Out of the 13 remaining patients, the treatment plan for nine was changed based on the results. Four out of nine were not on prebiopsy antibiotics and were started on tailored therapy. Five out of nine patients' preexisting antibiotic regimens were tailored. Of the 65 specimens that were successfully cultured by microbiology, 15 cultures were positive. This corresponds to a culture positivity rate of 23%. In summary, nine patients who underwent biopsy had their management changed on the basis of the microbiology report. However, the other 57/72 (87.5%) patients who underwent biopsy for culture did not have their treatment changed as a result.

Vertebral biopsies performed by radiology for suspected osteomyelitis 1/2003 to 3/2011

	N	% of total	N Culture result changed treatment	% Treatment changed
Osteo suspected clinically and biopsy ordered	72		Sep-72	12.50%
Biopsy sample successfully obtained	70	97.20%	Sep-70	12.90%
Positive Culture	15	23.10%	15-Sep	60.00%
Negative Culture	50	76.90%	0/50	0.0%
Error in transfer*	4			
Improper preparation**	1			

*Pathology was performed on specimen but the specimen was not received by microbiology

** Specimen sent in formalin and unable to be used for culture

Conclusion
Because (1) image-guided bone biopsies fail to provide an etiologic microorganism in most cases of clinically suspected osteomyelitis-diskitis and (2) in the setting of positive culture results broad-spectrum antibiotics often are continued unchanged, and (3) osteomyelitis is a clinical diagnosis and therefore a negative culture does not allow one to cease antibiotics in suspected cases: bone biopsy may not be a useful tool to guide treatment except in cases in which there is high clinical suspicion of an atypical organism such as tuberculosis.

Novel Approach to Teaching Fluoroscopic Neuroanatomy and Spine Injection Skills

Musco, J.·Nanda, A.·Davis, R.
University of Missouri
Columbia, MO.

Purpose
Learning and understanding fluoroscopic neuroanatomy and acquiring the skills to safely perform spine injections is an essential part of training for many radiology, neurology, neurosurgery, anesthesia, and physical medicine and rehabilitation residents. Unfortunately there are no inexpensive and easily accessible models available to simulate and teach this essential skill. Thus, much of the teaching and learning is done while the patient is on the fluoroscopy table using the "See one, do one, teach one" method.
Materials & Methods
We present a novel cost-effective approach to making a fluoroscopic simulator using a plastic spine model coated with a metallic adhesive. The adhesive was painted on the deconstructed plastic spine model and allowed to dry

overnight. The model then was reassembled and wrapped in a gel foam pillow to simulate placement of the needle in an actual patient.
Results
Although the plastic noncoated model was radiopaque we found it difficult to visualize smaller structures such as facet joints under fluoroscopy. Coating the plastic spine model with our metallic adhesive allowed for improved visualization of the plastic model under fluoroscopy. Improving visualization of smaller structures like facet joints allows the plastic model to become a useful tool for simulating and training residents to perform more advanced procedures like facet injections and nerve root blocks.
Conclusion
We were able to transform an inexpensive plastic model of the lumbar spine into a useful neuroanatomy fluoroscopic simulator device that can be used to teach fluoroscopic neuroanatomy and spine injection skills without subjecting patients to multiple needle placement attempts and unnecessary radiation.

Diffusion-Weighted Imaging of the Spinal Cord: Pictorial Essay and Review of Its Applications in Spinal Cord Pathology

Yañez, A.·Fuentes, P.·Fassler, X.·Gonzalez, M.
Instituto de Neurocirugía Asenjo
Santiago, CHILE.

Purpose
Diffusion-weighted imaging (DWI) is a widespread used technique in cerebral diseases; nevertheless the anatomical issues regarding the spine and spinal cord hinder the application of that sequence in this particular region. This pictorial essay reviews and shows the applications of DWI in spine and spinal cord diseases.
Materials & Methods
The MR DWI studies of the spine and spinal cord obtained in our center between April to December 2012 with a 1.5T unit were reviewed restropectively. The acquisition parameters were: TR 2500; TE 65 ms; NEX 32; 250 x 250 mm; acquisition matrix 128, slice numbers 12; slice thickness 3 mm, with an acquisition time of 2 minutes and 50 seconds.
Results
We present only confirmed cases (clinical, pathologic or laboratory confirmation) including dorsal spinal cord infarct, conus medullaris infarct, subarachnoid epidermoid cyst, aortic dissection with dorsal spinal cord infarct, paraspinal abscess secondary to spondylodiskitis, and lymphoma of the vertebral bodies.
Conclusion
Diffusion-weighted imaging of the spine and spinal cord is a reliable tool that can improve diagnostic accuracy in spinal cord pathology.

KEYWORDS: Diffusion-weighted imaging, Spinal cord, spine

Tailored Tube Current Reduction Strategy and Its Effect on Effective Patient Radiation Dose for CT-Guided Interventions

Swarnkar, A.[1]·Ezhapilli, S.[2]·Krishna, S.[1]·Ogden, K.[1]
[1]Upstate Medical University, Syracuse, NY, [2]Emory University, Atlanta, GA.

Purpose
CT is the preferred modality for many image-guided interventional procedures of the head, neck and spine. These procedures are associated with a high radiation dose to the patient due to multiple scans that are performed during the procedure. During performance of the scans sometimes limited information is required, such as location, depth and direction of the needle or catheter, and the tube current can be decreased significantly, thus decreasing the radiation dose. In this study we determined the magnitude of decrease in patient radiation dose without compromising the success of the image-guided procedure by using fractions of the tube current and tailoring it according to the extent of anatomical detail and information necessary.
Materials & Methods
We reviewed a total of 40 consecutive patients undergoing CT-guided interventional procedures such as biopsies, epidural blood patches, and abscess drainage. During each of these procedures, initially a diagnostic scan was performed using automatic mA setting on the scanner. Subsequent scans were performed with a fraction of the tube current (e.g., 1/2 the automated mA setting for discerning soft tissue detail like nerves, vessels or 1/16 the mA for identifying needle depth and direction). The actual dose length product (DLP) was recorded automatically at the end of each procedure. The estimated dose which the patient would have received if the dose was not reduced was calculated by scaling DLP by using the ratio of automated mA to actual mA used during the intervention. Dose length product was converted into the effective dose and the percentage reduction of the effective dose was calculated for each patient.
Results
The effective doses during the procedures ranged from 0.1mSV to 20mSV with an average of 5.19mSV (standard deviation of 4.33) whereas the estimated effective doses without such mA reduction strategy ranged from 0.2mSV to 30mSV with an average of 8.96mSV (SD 7.52). The average reduction of radiation dose was 38%.
Conclusion
Our study reveals that effective radiation doses during interventional procedures can be decreased without any negative impact and must be considered as a reasonable

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

approach to reduce effective patient radiation dose during these procedures. The extent of acceptable reduction of tube current is variable and is tailored to suit the need for anatomical detail and essential information for each procedure being performed.

KEYWORDS: Radiation safety

Improved Detection and Conspicuity of Multiple Sclerosis Spinal Cord Lesions by STIR Phase Imaging: A Retrospective Comparative Analysis

Nayak, N.[1]·Salah, R.[2]·Huang, J.[3,4]·Hathout, G.[1,3,4]
[1]University of California Los Angeles, Los Angeles, CA, [2]2David Geffen School of Medicine at University of California, Los Angeles, CA, [3]University of California Olive View Medical Center, Sylmar, CA, [4]Greater Los Angeles-West Los Angeles Veterans Administration Medical Center, Los Angeles, CA.

Purpose
Multiple sclerosis (MS) is the most common disabling CNS disease of young adults. MR imaging is used routinely to detect MS plaques in the brain and spinal cord. A significant portion of MS patients demonstrate spinal cord lesions at the time of initial workup, which are an important part of the McDonald criteria for diagnosis. However, whereas brain imaging sequences are now fairly standardized, debate continues regarding the optimal sequences for imaging the spinal cord. The short T1 inversion recovery (STIR) sequence has been shown in the current literature to improve lesion detection with its additive T1/T2 weighting, but current spinal cord imaging protocols from the Consortium on MS Center Consensus Guidelines do not include the STIR sequence. We demonstrate that not only do STIR sequences improve lesion detection compared directly to conventional T2-weighted sequences, but they also significantly improve lesion conspicuity, facilitating earlier positive diagnosis.
Materials & Methods
Dedicated MR spinal cord imaging of 29 sequential patients with clinically confirmed multiple sclerosis was analyzed retrospectively by two independent neuroradiologists in a novel study design. Sagittal T2-weighted and STIR sequence images from the same study for each patient were examined for MS plaques using a double-blinded review of individual images “separated in time and space,” such that STIR and T2 image pairs were never analyzed simultaneously. Number of lesions and individual lesion conspicuity, using a subjective scale (1-5), was tallied for each sequence. Averages for each observer were compared using a paired t-test analysis for statistical significance.
Results
Significantly more MS lesions were detected on STIR than on T2-weighted sequences for both observers ($p = 0.001$, and $p = .005$). In seven patients, the conventional T2 sequence detected no lesions at all, whereas STIR sequences showed significant cord involvement. Lesion conspicuity also was significantly better on STIR for both observers ($p < 0.0005$). For T2-weighted sequences, there was a statistically significant difference in the number of lesions detected between the two observers ($p = 0.003$), but there was no statistically significant difference on STIR ($p = 0.43$).

Conclusion
Short T1 inversion recovery sequence imaging not only significantly improves detection of MS lesions within the spinal cord, but also provides better contrast and conspicuity of visible lesions, creating a more confident diagnostic measure of MS extent and progression. STIR sequences of the spinal cord should be routinely obtained during initial and routine followup of MS.

KEYWORDS: Multiple sclerosis plaques, Spinal cord

eP-280

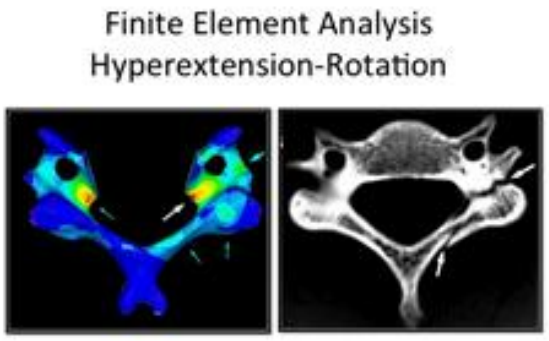
Pedicolaminar Fracture Separation: Validation of a Hyperextension-Rotation Mechanism by Biomechanical and Clinical Analysis

Gibbs, W. N.·Murphy, J. S.·Harris, J. H.·Heiserman, J. E.·Ross, J. S.·Dean, B. L.
Barrow Neurological Institute
Phoenix, AZ.

Purpose
The majority of cervical spine injury patterns have well described mechanisms of injury. The mechanism associated with pedicolaminar fracture separation (PLFS) remains controversial after five decades, since its original description. Pure PLFS is characterized by fracture of the ipsilateral pedicle and lamina, with tearing of the capsular ligaments allowing for rotation of the lateral mass. There is associated disruption of the anterior longitudinal ligament and intervertebral disk. Some authors have claimed that PLFS is a hyperextension-rotation injury, while others propose a hyperflexion-rotation, lateral hyperflexion, or pure axial rotation mechanism. We have evaluated the largest collection of PLFS cases reported to date utilizing advanced techniques in order to determine the dominant

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

mechanism of injury.
Materials & Methods
Ninety-three cases of cervical spine trauma with a component of PLFS were reviewed. Computed tomography (CT) of the cervical spine, as well as magnetic resonance imaging of the cervical spine and CT of the head, when available, were analyzed to determine the dominant vector of force, site of impact, and additional injuries. A three-dimensional, anatomically accurate, finite element model of the cervical spine was generated from CT images of a cadaveric human cervical spine. The magnitude and location of stresses upon the pedicle, lamina, and intervening articular mass were analyzed during simulated hyperextension-rotation. Subsequently, the simulated mechanisms of injury were applied directly to two human cadaver cervical spine specimens, which were load tested utilizing strain gauges applied to pedicle and lamina.
Results
Sixty-two percent (58/93) of cases demonstrated features of pure PLFS. Of these, the majority, 46% (43/93), resulted from a hyperextension-rotation mechanism and 16% (15/93) resulted from lateral hyperflexion. Thirty-eight percent (35/93) demonstrated features of severe hyperflexion injury with pedicle and laminar fractures. There was a near perfect correlation between sites of greatest stress depicted by finite element analysis during hyperextension-rotation and fracture location in the clinical cases. Strain gauge analysis verified all tested mechanisms as potential causes of PLFS.



Conclusion
Biomechanical and clinical analysis validates hyperextension-rotation as the most common mechanism of injury associated with pure PLFS. Lateral hyperflexion is a less common cause of PLFS. Severe hyperflexion with pedicle and laminar fractures is a more severe injury, with different fracture patterns. It should be considered a separate entity and different terminology should be applied. These distinct injury types can differ in prognosis and surgical approach. Correctly identifying and describing the injury type facilitates appropriate patient care.

Variations in Surgical Approaches to Lumbar Spine Disease: A Nationwide Survey and Analysis

Quencer, R. M.[1]·Modic, M. T.[2]·Obuchowski, N.[2]·Steinmetz, M. P.[3]·Wang, J. C.[2]·Williams, S.[1]·Lubelski, D.[2]·Mroz, T. E.[2]
[1]University of Miami Miller School of Medicine, Miami, FL, [2]Cleveland Clinic, Cleveland, OH, [3]Metro Health Medical Center, Cleveland, OH.

Purpose
Since it is widely recognized, but never documented, that surgical approaches to common lumbar spine disease are idiosyncratic, our primary purpose was to study treatment agreement among spine surgeons when faced with seven common spinal conditions. A secondary purpose was to see if there were significant differences between spine surgeons as a group versus subgroups such as specialty, geographic location, training, and time in practice.
Materials & Methods
An on-line survey containing seven cases of common lumbar spine pathology with a brief clinical history, representative conventional plain films, MR/CT imaging and surgical choices was sent to 3000 spine surgeons asking them to respond with their typical practice patterns. These cases included varying scenarios and manifestations of spondylolisthesis, recurrent disk herniation and mechanical back pain. Depending on the scenario, seven to ten potential treatment options were offered. The overall probability of two randomly chosen surgeons disagreeing on the treatment method given a particular scenario was computed. The probability then was computed within subgroups of surgeons and compared with overall levels of disagreement.
Results
Six hundred twenty-one of 3000 surgeons completed the survey. Treatment probability for disagreement for each survey scenario was: (1) two previous microdiskectomies with recurrence - 69%; (2) diskogenic pain 1 level - 76%; (3)degenerative spondylolisthesis without back pain - 73%; (4) degenerative spondylolisthesis with back pain 64%; (5) isthmic spondylolisthesis with L5 radiculopathy and back pain -69%; (6) one previous microdiskectomy with recurrence - 22%; (7) diskogenic pain 2 levels -75%. A representative scenario is included below. The highest probability for agreement (78%) was for a patient with one previous microdiskectomy with recurrent disk herniation. The lowest probability for agreement, 24%, was for a patient with diskogenic pain at one level. Given seven treatment choices for a scenario we would expect two surgeons to agree at least 14.3% of the time by chance alone.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Conclusion

If a patient with a common lumbar spine problem were to consult two different spinal surgeons there is a high likelihood that there would be significant probability for disagreement in their treatment recommendations. These widely variable surgical approaches to the same conditions are important for the neuroradiologist to recognize.

Normalization of Fractional Anisotropy and Apparent Diffusion Coefficient Values Below Regions of Moderate to Severe Spinal Canal Stenosis in the Cervical Spine

Pan, L.[1]·Tseng, I.[1]·Kanfi, A.[1]·Bhat, H.[2]·Porter, D.[2]·Sze, G.[1]
[1]Yale-New Haven Hospital, New Haven, CT, [2]Siemens, Malvern, PA.

Purpose

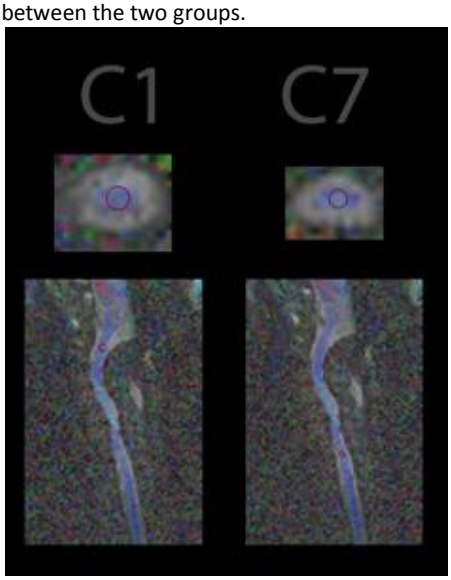
Past work has suggested that fractional anisotropy (FA) and apparent diffusion coefficient (ADC) values change predictably in regions of spinal canal stenosis. Theoretically, one could postulate that FA and ADC values below regions of significant stenosis also might be abnormal. However, this hypothesis has yet to be investigated. Our purpose is to characterize the change below the site of stenosis, if any. Understanding of FA and ADC values below the site of stenosis will further research into the pathophysiology of compressive myelopathy and improve our ability to characterize potential concomitant lesions in patient with spondylosis.

Materials & Methods

Diffusion-weighted images (DWI) of 18 patients on a 3T Siemens magnet using readout-segmented echo-planar imaging sequences in a sagittal orientation were evaluated retrospectively on a separate postprocessing workstation. Coronal and sagittal reformats guided the placement of an ovoid region of interest (ROI) within the confines of the spinal cord on the axial projection. The ROI was placed at the C1 and C7 vertebral body levels above and below the stenosis in all patients. The calculated FA and ADC values were compared to the values in 18 normal patients with no spinal canal stenosis. Statistical significance between the two groups was obtained using a 2-sample T-test.

Results

The DTI sequences in patients with moderate to severe cervical spine stenosis demonstrated a mean FA value of 676.7 and ADC value of 886.0 at the C1 level and a mean FA value of 624.4 and ADC value of 886.0 at the C7 level. The DTI sequences in patients with normal cervical spines demonstrated a mean FA value 705.85 and ADC value of 851.48.0 at the C1 level and a mean FA value of 715.8 and ADC value of 927.6 at the C7 level. The FA values decreased 7.69% in the patients with cervical spine stenosis and 2.69% in the normal patients, and the ADC values increased 23.2% in the patients with cervical spine stenosis and 8.94% in the normal patients. Using a 2-sample T-test, there was no statistically significant difference in the change of the FA and the ADC values between the two groups.



Conclusion

Normalization of FA and ADC values in the cervical spinal cord below the site of moderate to severe stenosis suggests recovery of diffusion properties in the cord.

KEYWORDS: DTI, Degenerative, FA ADC

Fluoroscopic-Guided Myelogram - Fluoro Time and Patient Body-Mass Index: A Baseline Study

Boddu, S. R.·Corey, A. S.·Saindane, A. M.·Applegate, K.·Fountain, A. J.
Emory University Hospital
Atlanta, GA.

Purpose

Evaluation of postoperative spine is a challenging situation. Myelography is the investigation of choice for pre-operative planning and assessment in patients with contraindications for MRI. Also the supplementary information provided by myelography in the presence of

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

metal hardware from spinal fixation prior to the revision surgery remains invaluable. There are no published guidelines for the acceptable range of fluoroscopic time for myelography. The study is aimed to obtain the baseline fluoroscopic time ranges for myelography involving different spinal levels and for varying body-mass index (BMI).

Materials & Methods

Retrospective review of all patients who underwent myelography at four hospitals over a one-year period (July 2011 - June 2012) was performed. Procedure logbooks, electronic medical records accessed for patient demographics, extent of myelography, prior history of spinal surgery, BMI, fluoroscopic time. Patients were categorized based on BMI and extent of myelography. Based on the federal obesity guidelines issued by National Heart, Lung and Blood Institute, patients were categorized into normal (18.5 - 24.9), over weight (25 - 29.9) and obese (≥ 30). Based on the extent of myelography patients were categorized into three subgroups: single level, two levels and whole spine. Logarithmic conversion of fluoroscopic times was performed to render normal distribution to the data. Fluoroscopic time was calculated for each subgroup and chi-square analysis was performed.

Results

Two hundred forty-seven successful (mean age 60 years, range 15-91 years, 51% male) fluoroscopic-guided lumbar approach procedures were performed. Six patients were excluded due to insufficient data. One hundred sixty patients had single level myelogram (5: cervical; 2: Thoracic; 153: Lumbar), 59 had two level myelogram (19: cervical +lumbar; 7: cervical +thoracic; 33: thoracic +lumbar) and 22 patients had total spine myelogram. Fourteen attending neuroradiologists and 14 fellows/residents participated. The mean fluoroscopic time for single level myelogram: 1.54 minutes (standard deviation: 0.79), for two level myelogram: 2.26 minutes (standard deviation: 0.89) and total spine myelogram: 2.32 minutes (standard deviation: 0.94). There was overall increased fluoroscopic time with increase in BMI as reported in Table 1. However the increase in the fluro time is not statistically significant (p = 0.43).

Table:1

BMI	Subgroups	Mean	95% CI
18.5 - 24.9	1 level2 LevelsWhole	1.42.091.65	1.13 - 1.671.57 - 2.612.48 - 4.42
25-29.9	1 level2 LevelsWhole	1.542.251.68	1.36 - 1.721.88 - 2.621.33 - 2.03
≥30	1 level2 LevelsWhole	1.62.392.57	1.39 - 1.812.03 - 2.751.12 - 4.02

Conclusion

In our study, fluoroscopic time for myelography increases with patient body-mass index (BMI) with no statistical significance. Baseline fluoroscopic times for single level; two levels and total spine myelography do not exceed five minutes. This study provides suggested fluoroscopy times based on the extent of myelography and patient body-mass index (BMI).

eP-284

Microwave Ablation of Spinal and Paraspinal Tumors: Initial Experience in Eleven Procedures

Kastler, A.[1,2]·Alnassan, H.[3]·Aubry, S.[4]·Kastler, B.[4,5]
[1]University Hospital, Clermont Ferrand, FRANCE, [2]I4S Laboratory EA 4268, Franche Comte University, Besançon, FRANCE, [3]I4S Laboratory EA 4268-IFR 133, Besançon, FRANCE, [4]University Hospital, Besançon, FRANCE, [5]I4S Laboratory EA 4268-IFR 133, Franche Comte University, Besançon, FRANCE.

Purpose

To evaluate the feasibility and efficacy of percutaneous microwave ablation (MWA) under CT guidance in the management of refractory pain in bone and soft tissue tumors in spinal and paraspinal locations.

Materials & Methods

Eleven MWA were performed in 10 adult patients using an Acculis MTA-2 Generator, 2.45GHz with a 17-gauge antenna. Topography of lesions were as follows: nine bone lesions (thoracic spine: 1, lumbar spine: 4, sacrum: 4) and two soft tissue lesions (paraspinal soft tissue). Six of eight bone lesions were osteolytic. All 11 ablated lesions were metastases (lung: 6, prostate: 2, leiomyosarcoma: 1, renal: 1). All procedures were performed with CT guidance under local anesthesia and nitrous oxyde. Followup was performed either by contrast ultrasound in case of soft tissue lesion or MRI in case of bone lesion. Pain prior procedure, immediately after and at distance was assessed using a VAS pain score.

Results

Lesion size ranged from 12 mm to 70 mm. Technical success was 100%. Mean ablation time was 4.75 minutes (1-13) with an average of 4.2 cycles per ablation lasting from 30 seconds to 3 minutes with a ablation power ranging from 30 to 160 W. Mean VAS before procedure was 7.11/10. Immediate pain relief was greater than or equal to 50% in 10/11 cases and lasted for an average of 4.85 months (range 0.5-15 months). No adverse events occurred during or after procedure.

Conclusion

Percutaneous MWA appears to be a feasible, safe, effective and fast technique for the management of refractory pain in spinal and parspinal tumors. Ablation time appears to be highly reduced compared to radiofrequency ablation.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eP-285

Value of High Viscosity Cement in Augmentation of Advanced Malignant Compression Fractures

Padwal, J.[1]·Georgy, M.[2]·Georgy, B.[1,3]
[1]University of California San Diego, San Diego, CA, [2]Canyon Crest Academy, San Diego, CA, [3]San Diego Imaging, San Diego, CA.

Purpose
Vertebral augmentation in malignant compression fractures is associated with higher complication rates compared to benign fractures. High viscosity cement is associated with lower leakage rate. We are investigating the value of high viscosity cement in vertebroplasty performed in cases of advanced malignant compression fracture.
Materials & Methods
Institutional board approval was obtained for this retrospective study. Twenty-six patients (17 females and 9 females with average age of 73.9) underwent vertebroplasty for pain control due to underlying different metastatic diseases were evaluated. A total of 37 levels treated. Postprocedure CT and radiographs were evaluated for presence and location of leakage.
Results
All treated levels had epidural tumor extension or cortical bone disruption or both (8 levels) in preprocedure CT or MR studies. On postprocedure CT images, there were 25 cement leakages (67%), 15 venous, right diskal, three epidural, and one leak in a neural foramen. Two levels show two different leaks. Postprocedure radiographs show 16 leakages (43%), seven venous and nine diskal. None of those leaks were of any clinical significance and required any further intervention.
Conclusion
Vertebral augmentation using high-viscosity cement in advanced malignant vertebral compression fracture is relatively safe. Although, there is a high cement leakage in postprocedures CT, still less than published data in benign lesions. All leakage reported are minimal and does not appear to have any clinical consequences.

KEYWORDS: Vertebral compression fractures, Vertebral augmentation

eP-286

Role of Lumbar Diskography in the Surgical Management of Patients with Axial Back Pain: A Single Center Retrospective Study

Bhatnagar, P.·Birchall, D.·Gregson, B.·Butteriss, D.
Royal Victoria Infirmary
Newcastle upon Tyne, UNITED KINGDOM.

Purpose
The intervertebral disk has been shown to be a cause of chronic lumbar spine pain without disk herniation in 26% to 39% cases. However, there is a lack of consensus in the literature regarding the diagnosis and treatment of these intervertebral disk disorders. The selection of appropriate patients for lumbar disk surgery is a challenging task involving a highly variable, multifactorial decision process complicated by a lack of reliable, validated clinical signs and imaging findings. Lumbar provocation diskography, which includes disk stimulation and morphologic evaluation, often is used to distinguish a painful disk from other potential sources of pain. The aim of this study was to investigate the role of diskography in the selection of patients with disk-related pain for fusion surgery and also to determine if these patients had any symptomatic improvement after the spinal fusion.
Materials & Methods
We carried out a retrospective study of 91 patients who had a lumbar diskography at our institution between June 2007 to November 2010. All patients were referred for axial back pain not manageable by conservative/medical means, and were being considered for attempted surgical management because imaging showed single or two-level disk degeneration. We reviewed the imaging, clinical notes and letters and collected data regarding patient demographics, a positive or negative diskography (including a nonconcordant result (i.e., pain from a normal disk, and not from a degenerative disk is counted as a negative result in terms of surgical decision making) whether or not the patient was treated with a surgical fusion of the abnormal level, and whether or not the pain improved. Statistical analysis was performed using the Fisher's Exact two-sided test and the Mann-Whitney test.
Results
Of the 91 patients, diskogram was positive for 56 cases and negative for 35 cases. We found that if a patient had a positive diskogram then they were more likely to have surgery (67% of those with positive diskogram had surgery compared with 17% of those with a negative diskogram) [Fisher's exact (2-sided) $p < 0.0001$]. In patients who had a positive diskogram, surgery was associated with symptomatic improvement in 32% of patients compared to only 5% who did not have surgery (Fisher's exact $p = 0.004$). However, 68% patients with positive diskogram had ongoing back pain despite surgery. There was no evidence of a relationship between the patient's age and the result of diskogram (Mann-Whitney test $p = 0.343$), between the age and having surgery (Mann-Whitney test p

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

= 0.346) or between the age and outcome of surgery (Mann-Whitney test p =0.971). There was some suggestion that women may be more likely to have a positive diskogram than men but more data would be needed to confirm this. Women also may be more likely to have surgery but again a larger sample would be needed to check.
Conclusion
Diskography is a useful investigation in the management of patients with diskogenic back pain and may contribute to improving the selection process of patients for spinal fusion surgery.

KEYWORDS: Diskography, Fusion

Teaching Fluoroscopic Neuroanatomy and Spine Injection Skills on a Modified Plastic Model of the Lumbar Spine

Musco, J.·Nanda, A.·Davis, R.
University of Missouri
Columbia, MO.

Purpose
Learning and understanding fluoroscopic neuroanatomy and acquiring the skills to safely perform spine injections is an essential part of training for many radiology, neurology, neurosurgery, anesthesia, and physical medicine and rehabilitation residents. Unfortunately there are no inexpensive and easily accessible models available to simulate and teach this essential skill. Thus, much of the teaching and learning is done while the patient is on the fluoroscopy table using the “See one, do one, teach one” method.
Materials & Methods
We present a novel cost-effective approach to making a fluoroscopic simulator using a plastic spine model coated with a metallic adhesive. The model then is wrapped in a gel foam pillow to provide stability for the spinal needle and to block the trainees view of the model. After reviewing general lumbar neuroanatomy using images obtained from the model, the trainees were provided with instructions on use of the fluoroscopy camera and basic needle handling technique and placement. The trainees then performed a series of mock procedures using the model. The mock procedures were monitored for total procedure time, total fluoroscopy time, and accuracy of needle placement.
Results
All trainees showed a statistically significant improvement in total procedure time, total fluoroscopy time, and accuracy of needle placement. After performing the mock procedures, trainees were more confident and felt as though they were now better prepared to perform the procedures on actual patients.
Conclusion
We were able to transform an inexpensive plastic model of the lumbar spine into a useful neuroanatomy fluoroscopic simulator device that can be used to teach fluoroscopic neuroanatomy and spine injection skills without subjecting patients to multiple needle placement attempts and unnecessary radiation.

Effect of Preprocedure Antibiotics on the Diagnostic Accuracy of Image-Guided Spinal Biopsy in Diagnosis of Vertebral Osteomyelitis and Diskitis

Gnerre, J. M.·Dickson, A.·Ortiz, A. O.
Winthrop University Hospital
Mineola, NY.

Purpose
To determine how pretreatment with antibiotics affects the diagnostic accuracy of image-guided biopsies of the spine exclusively for vertebral osteomyelitis and diskitis.
Materials & Methods
Data were examined from a retrospective case series of CT and fluoroscopically guided biopsies of 14 patients who received pretreatment with antibiotics for at least two consecutive days prior. The mean age of patients was 67 years, with a range of 38-83 years, including nine males and five females.
Results
In our series, only 23% of patients with confirmed vertebral osteomyelitis yielded a positive biopsy result (23% sensitivity, 100% specificity, 21% accuracy, 100% precision). And of those three patients, the condition usually was complicated by a severe infectious process that was grossly indicative of a spinal infection. One patient had a right psoas abscess, another had a lumbar abcess, which afforded these patients a larger sample area.
Conclusion
Image-guided biopsy of the spine is a safe and accurate tool for diagnosis of vertebral osteomyelitis and diskitis. Pretreatment with antimicrobial therapy prior to biopsy significantly reduces biopsy sensitivity and accuracy. Regardless of pretreatment, positive biopsy results are more likely when sampling patients with extensive infectious processes. Our results indicate that spinal biopsies should be performed as early as clinically possible in order to maximize its efficiency as a diagnostic tool for patients with suspected vertebral osteomyelitis and diskitis.

KEYWORDS: Osteomyelitis, Biopsies, diskitis

Interventional Neuroradiology Sympathetic Blocks

Massari, F.[1]·Tsai, N. T.[1]·Rumboldt, Z.[1]·Pedicelli, A.[2]·Bonaldi, G.[3]·Cianfoni, A.[4]
[1]Medical University of South Carolina, Charleston, SC, [2]Catholic University of Rome, A. Gemelli Hospital, Rome, ITALY, [3]Ospedali Riuniti, Bergamo, ITALY, [4]Neurocenter of Southern Switzerland, Lugano, SWITZERLAND.

Purpose
Aim of this presentation is to offer an overview on image-guided sympathetic blocks, focusing on specific indications, techniques, outcomes in four highly specialized medical center in USA and Western Europe, as well as comparison with literature.
Materials & Methods
Sympathetic blocks are used for diagnostic, prognostic and therapeutic purposes for painful and other conditions associated with sympathetic system dysfunctions. Main indications for sympathetic blockade are: Complex regional pain syndrome (CRPS), phantom limb pain, central pain, hyperhydrosis, acute pancreatitis, and abdominal viscera cancer pain. Stellate ganglion blocks are utilized for painful and nonpainful conditions related to sympathetic dysfunctions of head, neck and upper extremities. Thoracic sympathetic blocks are utilized for CRPS, postoperative analgesia, pain from fractured ribs, therapeutic control of hyperhydrosis of the upper limbs and torso, liver capsule pain after blunt trauma, acute postherpetic neuralgia, and premature ventricular contractions (PVCs). Coeliac plexus blocks are utilized in pain due to intra-abdominal cancer, stemming from organs innervated by coeliac plexus. Lumbar sympathetic blocks are utilized for CPRS of the lower extremities, herpes zoster, amputation stump pain and inoperable peripheral vascular vasospastic diseases of the lower limb. Superior hypogastric blocks are utilized for pelvic pain, and pelvic organs cancer pain (uterus, cervix, bladder, prostate, urethra, testes and ovaries). Impar ganglion blocks are utilized in coccydynia.
Results
The sympathetic nervous system has been implicated in numerous pain syndromes including neuropathic, vascular and visceral pain. In relation to this, in order to determine the sympathetic role in the transmission of pain and to manage these algic syndromes, sympathetic ganglia are targeted for local anesthetic blocks, for diagnostic, prognostic, and therapeutic purposes, balanced in a more complex pain treatment strategy, in the treatment of CRPS and other pain conditions. Safe and precise performance of these blocks requires knowledge of the loco-regional anatomy, accurate imaging guidance, and rigorous technique. Elements of relevant fluoroscopic and cross-sectional anatomy, procedural technique elements as well as outcomes are discussed and displayed.
Conclusion
This multicentric study summarizes indications, anatomy, techniques, outcomes in four highly specialized medical centers in USA and Western Europe, as well as comparison with literature, for the sympathetic blocks.

Retrograde Axonal Transport Is Impaired after Radiation Injury: Demonstration with Neurographic Molecular Imaging

Le Roux, L. G.·Bredow, S.·Grosshans, D.·Schellingerhout, D.
M. D. Anderson Cancer Center
Houston, TX.

Purpose
The goal of this study was to determine whether molecular imaging is a suitable technique to detect changes in the spinal cord in response to radiation injury.
Materials & Methods
The lower thoracic spinal cord of adult female BALB/c mice was irradiated with single doses of 2, 10, and 80 Gy. An optical imaging method utilizing the fluorescently labeled nontoxic C-fragment of tetanus toxin (TTc) was used to evaluate changes in the retrograde axonal transport mechanism, while Luxol fast blue staining served to assess demyelination in radiated cords.
Results
Transport of TTc in the thoracic spinal cord was impaired in a dose-dependent manner as early as two days after radiation. Transport was significantly decreased by 16 d in animals exposed to either 10 or 80, while animals exposed to 2 Gy remained unaffected. Further, animals exposed to the highest dose also experienced significant weight loss by nine d and developed posterior paralysis by 45 d. Demyelination in radiated cords could be observed after 30 d in mice exposed to 80 Gy.
Conclusion
Radiation of the spinal cord induces dose-dependent changes in the axonal transport mechanism which can be monitored by molecular imaging. This approach suggests a novel diagnostic modality to assess nerve injury and monitor therapeutic interventions.

KEYWORDS: Radiation toxicity, Spinal cord, molecular imaging

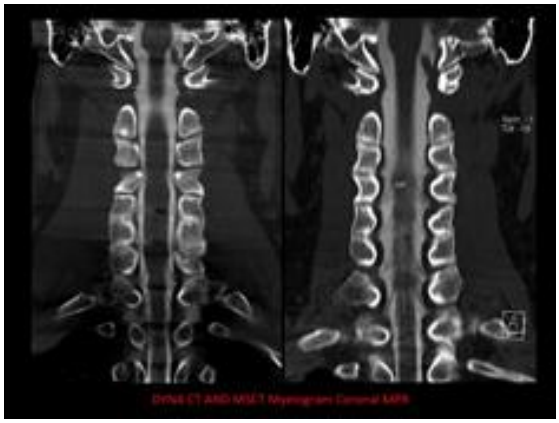
DYNA CT Myelography versus Multislice CT Myelography: Time for a Change?

Chaudry, I.[1]·Spiotta, A.[1]·Brooks, N.[2]·Turner, R.[1]·Fiorella, D.[3]·Turk, A.[1]
[1]Medical University of South Carolina, Charleston, SC, [2]University of Wisconsin School of Medicine and Public Health, Madison, WI, [3]Stony Brook University, Stony Brook, NY.

Purpose
There have been considerable improvements in C-arm angiographic flat-panel detectors and software reconstruction algorithms that allows for improved spatial resolution as well as osseous and soft tissue differentiation. Our goal was to compare multislice CT (MS CT) to angiographic CT (DYNA CT) in myelographic imaging, to evaluate the benefits of DYNA CT and its possible clinical applications.
Materials & Methods
In total, 70 consecutive patients with degenerative spine disease (cervical = 16, thoracic = 3, lumbar = 51) underwent DYNA CT and MS CT myelography. DYNA CT myelography was performed on a flat-panel Siemens Artis Zee biplane neuroangiography platform with images reconstructed on an independent Leonardo workstation. Multislice CT was performed on 16-slice Siemens or GE MSCT scanner with MPR images reconstructed locally. Four reviewers, two experienced neuroradiologists and two neurosurgeons will review all MS CT and DYNA CT source and MPR images for overall impression, contrast distribution, perceptibility of disks, perceptibility of bines, delineation of spinal canal, delineation of nerve roots, hardware artifact, overall diagnostic applicability. Images were scored on a 1-5 scale with 1 = very poor, 2 = poor, 3 = moderate, 4 = good and 5 = very good.
Results
Full data analysis is pending. To date, both CT and DYNA CT were found to be of diagnostic quality 98% and 95% of the time respectively. Fifty-one (71%) of the DYNA CTs were found to be of the same or better diagnostic quality while only 18 (26%) were found to be inferior but still of diagnostic quality. The DYNA CT scored better on perceptibility of bones, spinal canal and nerve roots when compared to MS CT. DYNA CT exceled at evaluation of nerve root evaluation but was limited by hardware artifact. We found that DYNA CT is comparable to MS CT and subjectively has better imaging quality in virgin spines but is inferior when orthopedic hardware is present.



Conclusion
DYNA CT myelography maybe useful in the evaluation of degenerative spine disease in the virgin spine. Pending software improvements with metal artifact correction software will likely improve these results. The results will be updated at the time of the meeting.

KEYWORDS: Myelography, DYNA CT

Comparison of Fractional Anisotropy and Apparent Diffusion Coefficient Values Measured on Axial versus Sagittally Acquired Cervical Spinal Cord Diffusion Tensor Imaging in Normal Subjects

Idowu, O.·Carrino, J.·Riley, L. H.·Izbudak, I.
Johns Hopkins Hospital
Baltimore, MD.

Purpose
Fractional anisotropy (FA) and mean diffusivity (MD) are commonly used quantitative parameters in diffusion tensor imaging (DTI) of the cervical spinal cord, subject to variability in regards to plane of imaging used for calculations and region of interest (ROI) placement. The aim of this study is to evaluate the differences in FA and MD values calculated at each cervical spine level when DTI analysis is performed on sagittal image acquisitions, versus axial image acquisitions in adult control subjects. On axial images the goal was to also evaluate the differences in FA and MD values between gray versus white matter, compared to the ROIs that contained both gray and white matter.
Materials & Methods
Diffusion tensor imaging was performed on five patients on a 3T Siemens MR system with imaging protocol consisting of a sagittal T1-weighted, sagittal T2-weighted and sagittal and axial DTI sequences. A total of 10 diffusion directions were applied with two b-values (0 and 1000 s/mm2). Diffusion tensor imaging analysis was performed using Siemens Neuro 3D software with FA and MD values calculated on both the axial and sagittal DTI acquisitions with ROIs that contained both gray and white matter. Region-specific FA and MD values also were calculated on

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

axial imaging with ROI placement in the central gray matter, and dorsal white matter. Nonparametric statistical analysis utilizing the Friedman and Wilcoxon signed rank tests was performed.

Results

Average (±SD) FA values in the cervical spine calculated on axial acquisitions measured 0.66±.02 (C2-C3), 0.61±.06 (C3-C4), 0.65±.05 (C4-C5), 0.65±.08 (C5-C6), 0.72±.03 (C6-C7) and 0.74±.07 (C7-T1). Average (±SD) FA values in the cervical spine calculated on sagittal acquisitions measured 0.72±.05 (C2-C3), 0.77±.11 (C3-C4), 0.71±.06 (C4-C5), 0.64±.11 (C5-C6), 0.61±.10 (C6-C7) and 0.67±.04 (C7-T1). No statistically significant differences were found between whole spine FA values calculated in the axial plane versus the sagittal plane. Average (±SD) MD values in the cervical spine calculated on axial acquisitions measured 0.95±.07 (C2-C3), 0.96±.05 (C3-C4), 0.93±.06 (C4-C5), 0.97±.13 (C5-C6), 0.89±.05 (C6-C7), and 0.95±.08 (C7-T1). Average(±SD) MD values in the cervical spine calculated on sagittal acquisitions 1.00±.10 (C2-C3), 0.79±.16 (C3-C4), 0.96±.09 (C4-C5), 0.92±.14 (C5-C6), 0.98±.12 (C6-C7) and 1.00±.13 (C7-T1). No statistically significant differences were found between whole spine MD values calculated in the axial plane versus the sagittal plane. Average (±SD) FA values with regions of interest placed in the gray matter measured 0.63±.05 (C2-C3), 0.55±.05 (C3-C4), 0.54±.02 (C4-C5), 0.54±.05 (C5-C6), 0.62±.09 (C6-C7) and 0.60 ±.09 (C7-T1). FA values were significantly lower in the gray matter in the spinal cord measured on axial DTI data compared to whole cord values at C2-C3, C3-C4, C4-C5 and C5-C6 ($p<0.05$), and trended towards lower values at the remaining cervical spine levels.

Conclusion

Preliminary results suggest that fractional anisotropy and mean diffusivity values at each cervical spine level do not significantly vary based on the DTI acquisition plane. FA values measured in the gray matter are lower than whole cord FA values measured on axial or sagittal acquired DTI which correlates with the spinal cord DTI study results in the literature.

eP-293

MR Neurography in Thoracic Outlet Syndrome: Bony Anomalies or Fibrous Bands Causing Selective T2 Lesions

Baumer, P.[1]·Kele, H.[2]·Antoniadis, G.[3]·Heiland, S.[1]·Bendszus, M.[1]·Pham, M.[1]
[1]University of Heidelberg, Heidelberg, GERMANY, [2]Center for Neurology, Hamburg, GERMANY, [3]University of Tübingen, Günzburg/Tübingen, GERMANY.

Purpose

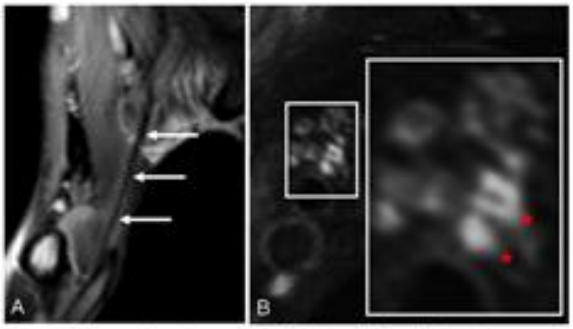
Neurologic diagnosis in thoracic outlet syndrome can be difficult. Until recently, neuroimaging has not offered more than confirmation or exclusion of cervical ribs in patients suspected with TOS. Visualization of fibrous bands in TOS has to our knowledge not been reliably achieved previously even though they are commonly found in-situ by surgeons and anatomists. We investigated whether MRI is able to visualize fibrous bands compressing the brachial plexus as well as T2 lesions within the affected roots or trunks.

Materials & Methods

High-resolution MR neurography was employed in 29 patients with a clinical diagnosis of true neurologic TOS or nonspecific TOS. The MRN protocol on a 3T unit (Verio, Siemens) included 3D SPACE STIR (TR/TE/TI 3800/267/180 ms, voxel size 0.781 x 0.781 x 0.8 mm^3, FoV 250, slices 72, averages 2) using a standard neck coil, sagittal-oblique T2 SPAIR (TR/TE 5530/45 ms, voxel size 0.469 x 0.469 x 3.0 mm^3, FoV 150, slices 51, averages 4) and 3D PD SPACE (TR/TE 1170/33 ms, voxel size 0.703 x 0.703 x 0.7mm^3, FoV 180, slices 51, averages 2) using custom made surface coils (NORAS GmbH, Würzburg, Germany) designed for imaging of the brachial plexus. SPACE sequences were used for 3D reconstruction of images.

Results

Five patients (17%) were identified with morphologic correlates of TOS. These included fibrous bands extending from cervical ribs to the first thoracic rib (Figure A), and pseudarthrosis or synostosis between ribs. A T2 lesion of the brachial plexus confirmed the diagnosis in all cases and was selective to the compressed portion (C8, inferior trunk, medial cord) (Figure B). Patients with true neurologic TOS as well as patients with nonspecific TOS exhibited these signal alterations.



Conclusion

Diagnosis of TOS can be confirmed by MR neurography. Morphologic correlates of TOS may exist even in nonspecific ("disputed") TOS. Anatomical anomalies visualized by MRI include fibrous bands that lead to selective T2 lesions of the brachial plexus.

Presurgical Location of the Adamkiewicz Artery in Thoracoabdominal Aortic Aneurysms: Comparison between Intra-Arterial CT Angiography and Intravenous CT Angiography

Gabrieli, J.[1,2]·Clarençon, F.[1]·Di Maria, F.[1]·Cormier, E.[1]·Sourour, N.[1]·Gaudric, J.[1]·Le Jean, L.[1]·Chiras, J.[1]
[1]Pitié-Salpêtrière Hospital Paris VI University, Paris, FRANCE, [2]University of Padua, Padua, ITALY.

Purpose
To compare the sensitivity of intra-arterial CT angiography (IA CTA) and intravenous CT angiography (IV CTA) for the presurgical location of the Adamkiewicz artery (AKA) in thoracoabdominal aortic aneurysms/dissections.
Materials & Methods
Retrospective study of 19 consecutive patients (median-age 67 years, age-range 42 to 81 years, six females) with thoracoabdominal aortic aneurysm (TAAA)/dissection (X TAAA, Y dissections). All patients underwent IA CTA on an hybrid angio-suite with injection of 100 cc of iodinated contrast material through a 5F pigtail catheter positioned at the origin of the descending aorta (injection rate 7 ml/s); the same patients also performed CTA with contrast administered through an antecubital vein at a rate of 5ml/s. Imaging findings were evaluated independently by two neuroradiologists with focus on the level of the origin of the AKA, on the visualization of the anterior spinal artery (ASA) and on its continuity with the aorta; the two latter also were assessed qualitatively by the readers as follows: no/poor visualization, fair visualization, good/excellent visualization.
Results
Adamkiewicz artery level was located in 74% of IA CTAs (14/19) versus 0% of CTA; ASA was visualized in 89% of IA CTAs (17/19) versus 47% of IV CTAs (9/19), a good/excellent visualization of the ASA was present on 58% of IA CTAs (11/19) which was never reported on IV CTAs; continuity with the aorta was seen on 84% of IA CTAs (16/19) versus 11% of IV CTAs (2/19), a good visualization of the continuity with the aorta was reported on 58% of IA CTAs (11/19) but never on IV CTAs.
Conclusion
Intra-arterial CTA is superior to conventional IV CTA for the location and visualization of the AKA and the ASA in patients with TAAA/aortic dissections; thus IA CTA seems to be a promising tool in the presurgical evaluation of these patients.

KEYWORDS: Adamkiewicz artery, Intra-arterial, CT angiography

Multiple-Site Epidural Blood Patch Administration through a Single Lumbar Puncture for Treatment of Cerebral Spinal Fluid Hypovolemia

Gemmete, J. J.·Chaudhary, N.·Pandey, A. S.
University of Michigan Hospitals
Ann Arbor, MI.

Purpose
An epidural blood patch (EBP) is accepted as a standard procedure to treat CSF hypovolemia. In quite a few cases, the CSF leak is spread over a large area along the spinal epidural space, making it difficult to identify the true leakage points. In such cases, autologous blood can be infused at multiple spinal levels with multiple entries. In this paper, the authors have devised a multiple-site EBP method with a single lumbar entry point by way of using a 4F vertebral catheter for continuous infusion. In this report, we introduce a new, single-entry, continuous multiple-site EBP administration technique and report the results we have obtained.
Materials & Methods
An EBP was applied via a 4F vertebral catheter in five patients with spontaneous CSF hypovolemia (three women and two men; mean age 35 years, range 22-53 years). The detection of an epidural CSF leak was based on the findings of an MRI gadolinium myelogram. In all cases, however, the leakage sites could not be identified clearly. The main symptoms of these patients were recurrent spontaneous chronic subdural hematoma (two patients), and orthostatic headache (five patients). All patients were placed prone on the angiographic table and biplane fluoroscopy utilized for guidance. After administration of local anesthetic, a 19G single wall needle was inserted into the epidural space at L2 below the conus medullaris which was confirmed with a contrast injection. A 0.035 inch glidewire then was advanced into the epidural space followed by a 10 cm 4F sheath. A 4F vertebral catheter was advanced over the wire to the level of C4. A small amount of contrast was injected into the epidural space to confirm approach position. Autologous blood was obtained from the patient through a peripheral intravenous and injected through the catheter as it was slowly moved in a caudal direction. Approximately 1cc of blood was injected at each vertebral level as it was pulled in a caudal direction to L2. An average of 45 cc, range 40 - 55 cc of blood was injected into the epidural space.
Results
The two spontaneous chronic subdural hematomas resolved at followup. In four patients, the orthostatic headache disappeared completely, and it was nearly relieved in one patient.
Conclusion
This new application method of an EBP with the aid of a 4F vertebral catheter enables infusion of a sufficient amount of autologous blood into multiple epidural areas with a single lumbar entry point.

Prevention of Oxaliplatin-Induced Neuropathy by Minocycline: Demonstration by Imaging and Behavioral Assessment

Flores, L. G.·Vichaya, E. G.·Le Roux, L. G.·Schellingerhout, D.
M. D. Anderson Cancer Center
Houston, TX.

Purpose
The purpose of our study was to utilize neurography, a new imaging technology evaluating retrograde transport, to determine if minocycline can prevent oxaliplatin-induced neuropathy, by using imaging with loss of retrograde axonal transport and pain behavior as biological readouts.
Materials & Methods
Female BALB/c mice received one of four treatments vehicle/vehicle, vehicle/minocycline, oxaliplatin/vehicle, or oxaliplatin/minocycline (n = 8/group). A 30 mg/kg cumulative dose of oxaliplatin or dextrose vehicle was given in 10 divided intraperitoneal doses across three weeks using a five days of treatment, five days rest, five days treatment administration paradigm. Furthermore, animals were treated daily with 50 mg/kg minocycline or 0.9% saline vehicle by oral gavage throughout the experiment beginning 48 hours prior to the first oxaliplatin treatment. To assess the impact of minocycline on oxaliplatin-induced neuropathy, both imaging and behavioral (i.e., mechanical sensitivity) data were assessed at baseline and each week for three weeks. For each imaging session, animals received fluorescently labeled TTc-Alexa790 (15 ug/20 uL) via intramuscular injection into the calf muscle. Fluorescent imaging (Xenogen IVIS 200) was used to image the distribution of TTc over 60 minutes, with ROI measurements taken over the lower thoracic spine to quantitate fluorescent uptake. Region of interest measurements had background activity subtracted, and were normalized to the signal intensity at time = 0. Mechanical sensitivity was assessed through the use of von Frey nylon filaments that produce calibrated force on the footpads. The 50% hind paw withdrawal threshold was calculated. At the end of the study tissue was harvested for immunohistochemical analysis.
Results
Oxaliplatin/vehicle treated animals showed a decrease in transport of TTc during weeks two and three, while the TTc transport of the vehicle/vehicle and oxaliplatin/minocycline remained stable across the experiment. The vehicle/minocycline group saw an increase in transport of TTc during weeks two and three. Similarly, the behavioral data indicated that oxaliplatin treatment resulted in increased mechanical sensitivity, while minocycline treatment abrogated this effect, such that animals in the oxaliplatin/vehicle group showed increased sensitivity compared to all other groups. This effect emerged within the first week of treatment and remained throughout the study. At week three there was a significant correlation between pain behavior and TTc transport.
Conclusion
Oxaliplatin causes decrease in retrograde axonal transport in the sciatic nerves and spinal cord, consistent with prior demonstrations. In this study we show that this effect can be attenuated by minocycline pretreatment. Behavioral and imaging data were correlated. This suggests that minocyclin can prevent the painful neuropathy induced by oxaliplatin, and that the mechanism of this effect might be related to retrograde axonal transport.

Odontoid Process Posterior Inclination in the Normal Adult and Adult Chiari 1 Population

Besachio, D. A.·Khaleel, Z.·Shah, L.
University of Utah
Salt Lake City, UT.

Purpose
Posterior odontoid process inclination has been associated with Chiari 1 malformation in the pediatric population. It has been proposed these findings need to be addressed during surgical decompression to improve outcome. To date, there is no literature to support the presence of abnormal odontoid inclination in adults who are diagnosed with a Chiari 1 malformation relative to the normal population. The purpose of this study is to evaluate the normal adult measurements for odontoid retroflexion, retroversion, and pB-C2 (posterior basion - posterior C2) line relative to a cohort of adults with Chiari 1 malformation to facilitate future research addressing surgical planning and treatment outcomes of Chiari 1 malformations in the adult population.
Materials & Methods
We performed a retrospective analysis of noncontrasted cervical spine CT scans of 150 consecutive adult control subjects obtained for indications other than Chiari I malformation. Three neuroradiologists performed the following measurements: odontoid retroflexion, odontoid retroversion, odontoid length, pB-C2 line and clivus-canal angle. Patients with trauma, mass lesion, extensive arthopathy or congenital anomaly of the craniocervical junction were excluded from the analysis. Identical measurements then were performed in a retrospective fashion for a cohort of 42 adult Chiari 1 malformation subjects using MRI in the Chiari 1 population. Statistical analysis then was applied to these unpaired data sets to determine if a significant difference was present between the two groups.
Results

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

One hundred twenty-five out of 150 control patients met the inclusion criteria. Of those, 80 were male and 45 were female with mean age of 52 years (range of 18 - 89 years). Odontoid retroflexion angle ranged from 70 to 89 degrees (mean 79.3), odontoid retroversion angle ranged from 57 to 87 degrees (mean 71.9) and clivus-canal angle ranged from 140 to 194 degrees. The range and mean of odontoid process length were 17.7- 26.2 mm and 21.7 mm, respectively. The mean of pB-C2 line was 6.5 mm with a range of 0 - 11.2 mm. A cohort of 42 subjects with Chiari 1 malformation was identified. Of those, 15 were male and 27 were female with a mean age of 34 years (range of 18-61 years). In female subjects, a significant difference between control and Chiari 1 subjects was identified with respect to odontoid retroversion (68 and 71 degrees), clivus-canal angle (164 and 158 degrees), and pb-C2 line (4 mm versus 5 mm). No difference was found in odontoid process retroflexion or length. No significant measured difference was found between male control and Chiari 1 subjects.

Conclusion

Our study suggests a significantly greater degree of odontoid retroflexion, retroversion, and difference in odontoid process length between normal adult males and females. Furthermore, retroversion of the odontoid process with more tissue projecting posterior to the pB-C2 line, and alignment of the craniovertebral junction is significantly different between adult female control subjects and adult female Chiari 1 patients. There may be a role for addressing these specific anatomical findings in surgical management of this subset of the Chiari 1 population.

KEYWORDS: Chiari malformation type 1, Odontoid

Emergent MR Imaging of the Spine after Hours

Black, D. F.·Erickson, B. J.·Hunt, C.·Diehn, F. E.·Gilbertson, J.·Timothy, K. J.·Rydberg, C.·Morris, J. M.·Wood, C. P.
Mayo Clinic
Rochester, MN.

Purpose

Evaluate after-hours emergent spine MRI utilization trends and impact on patient management over the past 13 years at our tertiary care referral center. Specifically, determine how often emergent MRIs alter management and the timing of definitive therapies provided.

Material & Methods

Following approval by our internal review board, we obtained MRI reports from all emergent spine MRIs which at our institution were completed during weekdays from 10 pm - 6 am and weekends from 2 pm - 6 am over the last 13 years. We found 179 emergent, after-hour MRIs of the spine and reviewed each patients' medical record in order to record the spinal region imaged, patient age and gender, category of finding (ex: traumatic, neoplastic, infectious, etc…), presence of cord compression, type of intervention generated by the MRI result (surgery, radiation, antibiotics, steroids), and the time interval between finishing the MRI examination and administering therapy.

Results

The number of after-hours spine MRIs performed has increased steadily from eight per year to 23 per year over the 13-year period. Overall, 75/179 (42%) had no significant findings. Positive findings consisted of the following pathologic categories: 23% traumatic, 15% neoplastic, 7% infectious, and 3% had acute degenerative changes. Forty percent (72/179) of scans demonstrated an intramedullary (12/179) or extramedullary (60/179) lesion affecting either the cord or cauda equina. Of these, 56% went on to surgery, 43% had steroids, 11% had radiation, and 8% were treated with antibiotics. Overall, 29% (52/179) underwent surgery to treat pathologies identified on imaging. Only 2% (4/179) of patients went to surgery within three hours of completing their emergent MRI. Only 6% (10/179) went to surgery within six hours and 16% (29/179) had surgery within 12 hours of completing their MRI scan. Overall, only 5% (8/179) of patients undergoing emergent spine MRI had findings that were treated with urgent radiation therapy and most of these were within 12 to 24 hours of completing their MRI scan. Only 1% (2/179) of patients were treated with radiation within six hours of completing their MRI scan. Of those treated with steroids 39/179 (22%), 41% were treated within three hours of completion of their MRI scan. Of the 12/179 (7)% treated with antibiotics, 50% were treated within three hours of completion of their MRI scan.

Conclusion

Clinical use of emergent spine MRI is increasing steadily over the last 13 years at our institution. While MR imaging discerned significant clinical findings, performing emergent studies overnight rarely results in immediate surgical intervention which, most often, is undertaken six hours or more after completion of the MRI with only 6% of after-hours scans resulting in surgery within six hours of the MRI scan. Only 1% of patients were treated within three hours of completing the MRI with radiotherapy. While immediate surgical and radiation therapies are uncommon, patients that were treated with either steroid or antibiotics for their MRI findings were much more likely to receive these interventions within three hours.

eP-299

Potential Biomechanical Implications of Thoracic Curvature Shape and Thoracic Kyphotic Angle in Elderly Women without Vertebral Compression Fracture

Enterkin, J.[1]·Bartynski, W.[1]·Petropoulou, K.[2]·Bartynski, S.[2]·Madrecha, J.[2]·Amrhein, T.[1]
[1]Medical University of South Carolina, Charleston, SC, [2]University of Pittsburgh, Pittsburgh, PA.

Purpose
The thoracic kyphotic angle (TKA) increases with age. A group of elderly patients (≥ 65 years old) has been identified with an increased TKA without evidence of a vertebral compression fracture (VCF) but with bimodal TKA distribution noted, high TKAs potentially increasing vertebral body stress. Exaggerated thoracic kyphosis is known to affect spine loads and balance in the elderly. The purpose of this study is to evaluate the thoracic curvature shape and TKA in senior women without compression fracture to better characterize potential biomechanical impact of TKA increase.
Materials & Methods
Ninety-six elderly women (≥ 65 years old) were identified without evidence of vertebral compression fracture/wedge deformity on digital lateral chest x-ray. The TKA (Cobb angle) was measured utilizing available PACS software (Stentor) from the T1-T2 level to the T12-L1 level based on endplate visualization. The shape of the thoracic curvature was classified into four distinct recognizable subgroups: 1) gentile-uniform curvature, 2) dominant-upper-thoracic curvature (between T1 and T5), 3) dominant-middle-thoracic curvature (between T4 and T8), and dominant-lower-thoracic curvature (between T8 and T12). Thoracic curve shapes and associated average TKAs were compared.
Results
Gentile-uniform shape was noted in 63 of 96 (65%) patients with dominant middle-thoracic curvature seen in 19 of 96 (20%), dominant upper-thoracic curvature in 12 of 96 (13%) and dominant lower-thoracic curvature in two of 96 (2%). A difference in TKA was noted between the observed curve shapes. Average TKA was greatest in patients with dominant middle-thoracic curvature (48°) with lower TKA in patients with gentile-thoracic curvature (44°) and dominant lower-thoracic curvature (41°). Surprisingly, average TKA was only 30° degrees in patients with dominant upper-thoracic curvature. Bimodal distribution was noted in the dataset when all curve shapes were combined, Bimodal distribution was noted in the patients with gentile-uniform curve shape, further suggesting a subgroup at risk even with gentile curvature.
Conclusion
Distinct differences in thoracic curvature shape and average TKA are noted in elderly women without evidence of compression fracture. Dominant focal middle-thoracic curvature and those with high TKA gentile curvature might have important implications in the development of thoraco-lumbar junction VCF and balance stability. Thoracic kyphotic angle and thoracic curve shape are likely important to consider when developing thoracic spine biomechanical loading models.

Evaluation of the Upper Cervical Spine in MR Imaging of the Brain: A Frequently Overlooked Region

Raz, E.[1]·Saba, L.[2]·Ozsvath, J.[1]·D'Ambrosio, F.[3]·Knopp, E.[1]·Fatterpekar, G.[1]
[1]New York University, New York, NY, [2]University of Cagliari, Cagliari, ITALY, [3]Sapienza University, Rome, ITALY.

Purpose
The standard protocol for brain contrast MRI includes the high-resolution T1-MPRAGE which usually covers the upper cervical spine (UCS): the 3D slab can be extended inferiorly to cover the UCS without prolonging the scan time. We aim to describe the characteristics and frequency of positive findings in the UCS region in a consecutive cohort of patients undergoing a contrast brain MRI, in which the T1-MPRAGE sequence was performed.
Materials & Methods
One hundred consecutive patients that underwent a contrast brain MRI as part of their routine clinical care have been evaluated. Exclusion criteria were the lack of T1-MPRAGE sequence in the protocol and presence of substantial motion artifact. The following have been evaluated: reason for the exam, lower coverage of the T1-MPRAGE (expressed as spinal level), lower coverage of the conventional sequences, extra Z-axis coverage of the T1-MPRAGE in cm. Statistical analysis was performed to evaluate the incidence of findings in the UCS which can be visualized using the T1-MPRAGE of the brain and to evaluate the difference of coverage with respect to different reason for exam.
Results
Six patients were excluded (four cases for motion artifact and in two cases no T1-MPRAGE was obtained) with remaining 94 patients (64 F, 30 M) with a mean age of 45.8 (18.5) years included in the study. The reason for the exam was: followup for brain tumor (n = 35), followup for demyelinating disease (n = 30), vascular malformation (n = 4), various other reasons (n = 25), including, suspected mass, headaches, vertigo. The T1-MPRAGE on average allowed for an extra 3.7 (1.6) cm Z-axis coverage compared to the conventional sequences ($p<0.001$). In 15 cases (15.9% of the cases; Fisher's exact test: $p<0.0001$), the extended coverage allowed for visualization of additional findings: leptomeningeal disease (n = 2), intramedullary lesions (n = 1), nerve sheath tumors (n = 2) and degenerative disease involving the craniocervical junction (n = 9).
Conclusion
T1-MPRAGE, performed as part of the standard protocol

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

for contrast brain MRI covers the UCS, not visible with the routine sequences. This can demonstrate additional findings that in some cases can be deemed clinically significant.

KEYWORDS: Spinal cord, Incidental findings

Cerebrospinal Fluid Flow Disruption and the Presyrinx State: Imaging Findings and Pathophysiology of a Reversible Myelopathic Condition

Tamrazi, B.·Chin, C.
University of California San Francisco
San Francisco, CA.

Purpose
The purpose of this study is to discuss the pathophysiology, imaging findings, and management of the presyrinx state. The development of syringomyelia secondary to obstruction of CSF flow is well documented in the neuroradiology literature. However the concept of a presyrinx state is not well understood and exists as part of the spectrum of syringomyelia. We will demonstrate the distinct imaging findings and clinical presentation of this potentially reversible condition to help radiologists recognize this entity and ultimately clinicians to promptly manage the patient prior to the development of an irreversible myelopathy.
Materials & Methods
Three patients with imaging and clinical findings of myelopathy were examined in this retrospective review. The patients were found to have evidence of CSF flow disruption secondary to transverse myelitis with cord expansion as well as chronic subdural collections leading to spinal cord intraparenchymal T2 prolongation on MRI without cavitation/syrinx formation. These findings were seen to improve after surgical intervention to alleviate the underlying source of CSF flow obstruction supporting the concept of a potentially reversible myelopathic condition, previously described as a presyrinx state.
Results
Disturbances in CSF flow in the subarachnoid space can potentially lead to a spectrum of pathologies, ranging from reversible to irreversible myelopathy in the form of presyrinx and ultimately syrinx. Cerebrospinal fluid flows from the subarachnoid space into perivascular spaces of the spinal cord and ultimately into the interstitial spaces towards the central canal. Under certain conditions where there is an obstruction to CSF flow such as in cases of arachnoid adhesions, mass lesion, or transverse myelitis causing cord expansion, CSF flow is altered creating edema within the cord. This is distinct from a syrinx where there is formation of a cavity in the cord. Differences on MRI include T2 prolongation without evidence of cavitation, a central canal that is not enlarged, as well as evidence of mechanical obstruction to CSF flow such as degenerative spondylosis causing canal narrowing as well as extra-axial collections such as chronic subdural hematomas. These findings were seen to improve following surgical intervention to alleviate the obstruction with re-establishment of normal CSF flow (Figure 1).

Conclusion
Disturbances in CSF flow dynamics cause a spectrum of myelopathic conditions, including the potentially reversible presyrinx state. This study illustrates the underlying pathophysiology and imaging findings of the presyrinx in order to help radiologists identify this relatively unknown reversible condition to ultimately prevent further progression to permanent myelopathy.

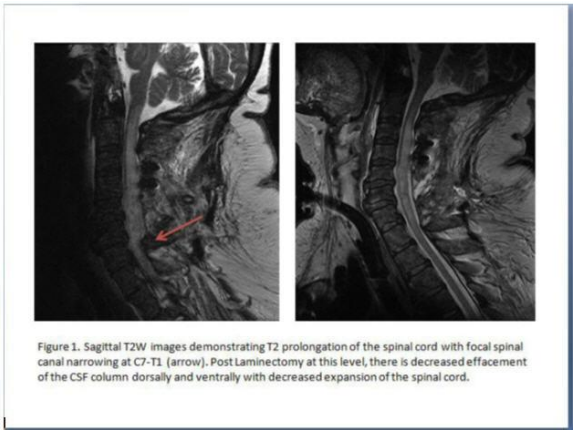

Figure 1. Sagittal T2W images demonstrating T2 prolongation of the spinal cord with focal spinal canal narrowing at C7-T1 (arrow). Post Laminectomy at this level, there is decreased effacement of the CSF column dorsally and ventrally with decreased expansion of the spinal cord.

eP-302

Prevalence of Unsuspected Sacral Insufficiency Fractures in Patients Undergoing Lumbar Spine MR Imaging

Myneni, M. C.·Vinson, E. N.
Duke University Medical Center
Durham, NC.

Purpose
Sacral insufficiency fractures are an uncommon cause of low back pain and have an increased incidence in the elderly and in patients who have undergone prior external beam radiation therapy to the pelvis. Due to the widespread use of lumbar spine MR imaging to evaluate patients with low back pain and/or neurologic symptoms, unsuspected sacral insufficiency fractures occasionally are detected on the inferior-most axial images through the lumbar spine. The purposes of this study are to find the prevalence of sacral insufficiency fractures detected on routine MR of the lumbar spine and to determine the most sensitive routine sequence at detecting these fractures.
Materials & Methods
Two musculoskeletal-trained radiologists retrospectively reviewed 600 consecutive lumbar spine MR examinations and noted the presence or absence of signal abnormality at the superior sacrum. A fracture was diagnosed when signal abnormality was present and a linear component

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

and/or abnormal morphology of the sacral cortex was visible on one or more imaging sequences. The original dictated report was reviewed in each case to determine if a sacral insufficiency fracture was diagnosed. If follow-up imaging was obtained to confirm or refute the presence of a sacral fracture, those images and reports were reviewed as well. In those patients with fractures, the signal characteristics, location, and most useful routine diagnostic sequence were recorded.
Results
Fractures of the superior sacrum were visualized in six (1%) of the 600 lumbar spine studies; five (83.3%) of them were unilateral, and one (16.7%) was bilateral. The average age of patients with sacral fractures was 61.5 years (range, 42-91 years). The most useful diagnostic sequence was the axial T1-weighted sequence. Review of the original dictated report revealed that the diagnosis of sacral insufficiency fracture was made in five (83.3%) of the cases.
Conclusion
Sacral insufficiency fractures are an important and likely under-recognized cause of low back pain. These fractures occasionally are seen on routine MR imaging of the lumbar spine, and were present in 1% of lumbar spine studies in this series. The axial T1-weighted images were more useful than the axial or sagittal T2-weighted images, likely due to the nonfat-suppressed nature of the axial T2-weighted images, and to the location of the fractures lateral to the typical field-of-view of the sagittal images. Paying particular attention to the bone marrow signal intensity in the superior sacrum on the most inferior axial T1-weighted images may improve one's ability to diagnose these fractures as a potential etiology of low back pain and thus improve the diagnostic utility of lumbar MR imaging in the evaluation of patients with nonspecific low back pain.

Evaluation of the Intervertebral Disk Angle for the Assessment of Anterior Cervical Diskoligamentous Injury

Howell, M.·Fakhran, S.·Alhilali, L.
University of Pittsburgh Medical Center
Pittsburgh, PA.

Purpose
The anterior diskoligamentous complex (ADL) is important to cervical spinal stability. Subjective widening of the disk space after trauma has been used to gauge ADL disruption on CT, but no quantitative CT measurements exist to evaluate injury. The purpose of our study was to evaluate if an increased intervertebral disk angle (IDA) could serve as a more sensitive, reproducible indicator of ADL disruption compared to subjective assesment.
Materials & Methods
Intervertebral disk angle was measured retrospectively on CT for 122 disk levels with ADL disruption by MR and 1095 disk levels with an intact ADL by MR. Intervertebral disk angle was measured between the anterior superior endplate and anterior inferior endplate, with angle apex at the mid posterior disk. Area under the receiver operating characteristic curves (AUC) for subjective disk widening and specific angle values were obtained. Intervertebral disk angle reproducibility also was evaluated.
Results
Intervertebral disk angle measurements were "substantially reproducible". No disk with intact ADL had an IDA greater than 18° or two standard deviations (SD) from the average IDA of the remaining disks. Area under the receiver operating characteristic curves for a criterion of subjective disk widening was 0.58. Area under the receiver operating characteristic curves for objective criteria, IDA greater than 13 or IDA above one SD from normal values, was 0.85. Maximal AUC was achieved if IDA greater than two SD from the average IDA of the other disks was used (0.86).
Conclusion
Subjective disk widening does not accurately detect ADL disruption on CT; an elevated IDA provides a more sensitive and objective measurement to help to direct further imaging in trauma patients.

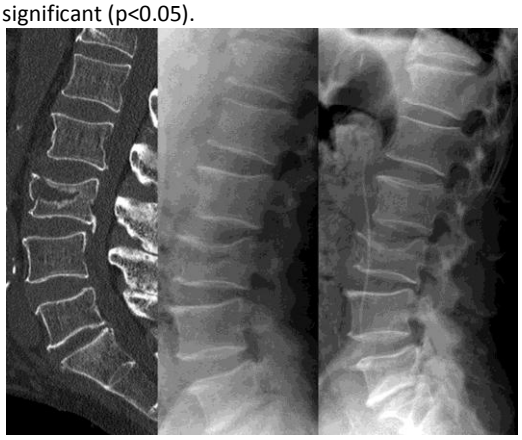
Intraosseous Fluid Sign Predicts Dynamic Vertebral Fracture Mobility

Stein, J. M.·Shah, L. M.
University of Utah
Salt Lake City, UT.

Purpose
Corticocancellous disruption and weakened trabecular bone due to osteoporosis or a marrow replacement process may manifest as an intraosseous fluid sign on CT and/or MRI. This may predict mobility of vertebral body fractures with dynamic maneuvers. Awareness of this potential vertebral collapse may affect patient management.
Materials & Methods
Following IRB approval, the RIS was queried for "fracture" in CT of the thoracic or lumbar spine from March 2011 to 2012. Those CT cases with acute or subacute (< 1 month) fractures and follow-up lateral upright radiographs within one week, with or without MRI, were included. Flexion-distraction injuries were excluded. The fracture type and chronicity were categorized as compression or burst and acute or subacute, respectively. The CT and MRI exams, if available, were evaluated for intraosseous fluid attenuation and signal intensity, respectively. Lateral upright radiographs within one week of the initial imaging were assessed semiquantitatively for further vertebral height loss. A Fisher's exact test was performed.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Results
The study population included 17 females and 16 males with an average age of 55 years. Spinal segmental locations of the fractures were thoracic and lumbar. There were 41 fractures, of which 23 were compression fractures and 18 burst-type fractures. Of these fractures, 17/41 (41%) had the fluid sign, 11 of which (59%) demonstrated dynamic vertebral height loss on upright radiographs. All of the fractures with a fluid sign and dynamic vertebral body height loss displayed less than 50% loss of height. Three cases showed dynamic vertebral height loss but did not have the fluid sign (13%). Dynamic vertebral body fractures demonstrated an average of 16.4% decreased vertebral body height and six degrees increased kyphosis on upright lateral radiographs compared to supine CT. Of those patients with dynamic loss of vertebral height, the majority (93%) were treated conservatively. Persistent back pain required kyphoplasty in one patient and spinal fixation in two patients. Fluid sign predictive of dynamic vertebral body mobility was found to be statistically significant ($p<0.05$).



Conclusion
Those vertebral body fractures with an intraosseous fluid sign on CT +/- MRI have an increased risk of dynamic mobility on upright radiographs compared to those fractures without an intraosseous fluid sign. Vertebral body height loss was less than 50%. Radiologists need to be aware of the predictability of this dynamic vertebral body height loss, which can be suggested by the intraosseous fluid sign.

Supporting Roles of Susceptibility-Weighted Imaging and Time-of-Flight MR Angiography Sequences in the Diagnosis and Characterization of Dural Arteriovenous Fistulas

Weisman, N. J.·Matouk, C.·Johnson, M.·Minja, F.
Yale New Haven Hospital
New Haven, CT.

Purpose
To demonstrate the corroboratory roles of susceptibility-weighted imaging (SWI) and time-of-flight MR angiography (TOF MRA) sequences in the diagnosis and characterization of dural arteriovenous fistulas (dAVFs).
Approach/Methods
We present a series of six dAVF patients imaged with both SWI and TOF MRA sequences. The fistulous site, degree of cortical venous reflux (CVR) and associated pseudophlebitic pattern (PPP) were evaluated and confirmed with digital subtraction angiography (DSA), the gold standard diagnostic technique.
Findings/Discussion
Recognition of hyperintense venous signal on SWI and TOF MRA images is an important clue in the diagnosis of dAVFs and fistulous point identification. The hyperintense signal noted on TOF MRA images is due to the “time-of-flight” effect of arterialized venous blood flow. Susceptibility-weighted imaging venous hyperintensity in dAVF patients may be secondary to a combination of this “time-of-flight” effect and diamagnetic oxygenated blood. Given these similarities, SWI and TOFMRA sequences may be regarded as complimentary in the diagnosis of dAVFs. In our study, the fistulous point was accurately identified in all six patients on SWI and TOF MRA images. In addition to fistulous point identification, SWI and MRA identified 100% (four of four) patients with CVR and PPP confirmed on DSA; features correlated with an increased risk of

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

intraparenchymal hemorrhage. Both sequences tended to underestimate the degree of PPP when compared to DSA in three of the four patients with CVR.
Summary/Conclusion
Susceptibility-weighted imaging and TOF MRA are complementary noncontrast, noninvasive MRI sequences that can be used to accurately diagnose dAVFs. They also may be useful tools in the routine management and followup of patients with dAVFs.

KEYWORDS: Dural arteriovenous fistula

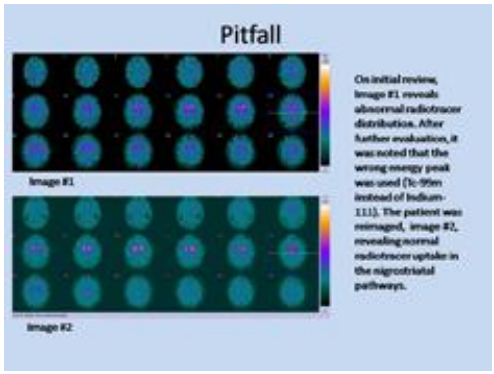
Pearls and Pitfalls of I-123 Ioflupane (DATscan) SPECT Imaging: What the Radiologist and Clinician Need to Know

Chaudhry, A. A.[1]·Gul, M.[2]·Matthews, R.[1]·Franceschi, D.[1]
[1]Stony Brook University Medical Center, Stony Brook, NY,
[2]Winthrop University Hospital, Mineola, NY.

Purpose
1. Review the anatomy, pathophysiology, and imaging findings including SPECT imaging (DATscan), CT, and MRI of various movement disorders including Parkinson disease and supranuclear palsy. 2. Review pearls and pitfalls of SPECT Imaging.
Approach/Methods
1. Review of nigrostriatum I-123 Ioflupane imaging highlighting study technique and clinical indications. 2. Review approach to SPECT study interpretation. 3. Review imaging findings of I-123 Ioflupane for various movement disorders and their respective differential diagnoses. 4. Review radiologic pitfalls and emphasize key points which can help in avoiding these pitfalls. 5. Review clinical and radiologic pearls that can help narrow the differential diagnosis.
Findings/Discussion
1. Detailed physiologic and pharmacologic discussion of I-123. 2. Case-based discussion of clinical features, pathophysiology, histology features, imaging findings (SPECT, CT and/or MRI) highlighting radiologic pearls, treatments and prognosis of various movement disorders. 3. Case-based discussion of various pitfalls of I-123 Ioflupane imaging along with reviewing clinical and radiology findings that can help in arriving at the correct diagnosis.



Summary/Conclusion
1. I-123 Ioflupane nigrostriaum imaging is a valuable functional imaging modality in evaluation of various movement disorders including Parkinson disease, essential tremor, pseudoparkinsonism, and progressive supranuclear palsy. 2. By the conclusion of this presentation, the radiologist should have a better understanding of I-123 Ioflupane findings of various movement disorders. 3. Differential diagnosis can be narrowed utilizing age, clinical findings and imaging characteristics on I-123 Ioflupane imaging to avoid common pitfalls.

EdE-04

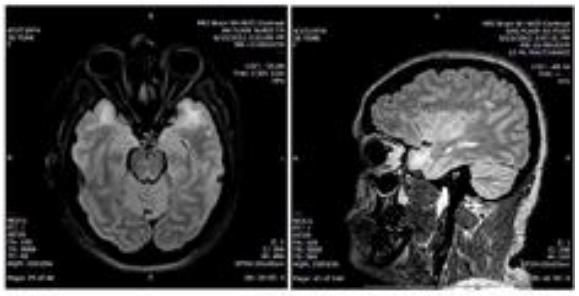
***"Put Your Money Where Your Temporal Lobe Is"*: The Unique Imaging Characteristics of CADASIL**

Morris, J.·Li, S.
Baystate Medical Center
Springfield, MA.

Purpose
CADASIL is the most common heritable cause of stroke and vascular dementia. Clinically, it presents with nonspecific symptoms including migraines, early-onset TIAs, mood disturbance, and progressive cognitive decline. Imaging of patients with CADASIL commonly yields white matter hyperintensity (WMH), a nonspecific finding seen in many disorders. This discussion will elucidate the MRI findings that differentiate CADASIL from imaging mimickers.
Approach/Methods
Compare the imaging findings associated with CADASIL to those of other disorders involving WMH.
Findings/Discussion
A constellation of unique MRI findings suggests the diagnosis of CADASIL. The typical MRI progression begins at age 20-30 with symmetric punctate or nodular periventricular and centrum semiovale WMH on T2-weighted and FLAIR sequences. Lesions increase in prevalence and extent with age, coalescing into larger patchy WMH at age 30-40, specifically in the external capsules (66% of cases) and anterior temporal lobes (60%

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

of cases), but sparing the medulla; lacunar infarcts become apparent at this age as well. Microhemorrhages follow, and eventual T1-weighted hypointensities result from severe tissue damage. Other generic neuroimaging findings also are seen, including dilated perivascular spaces and age-incongruent brain atrophy. White matter hyperintensities are ubiquitous, and thus MRI mimickers of CADASIL are frequent. In many cases clinical history excludes CADASIL, but not always. Notably, none of the following disorders demonstrate symmetric WMH in the anterior temporal lobes or external capsules, but a short discussion of their imaging findings is still warranted. Small vessel ischemic disease WMH is asymmetric and subcortical/periventricular, generally seen in association with risk factors for ischemia. Multiple sclerosis presents with WMH, but lesions never involve the basal ganglia or thalamus, whereas CADASIL lesions do. Cerebral amyloid angiopathy causes WMH as well, but evidence of hemorrhage always parallels the finding. The WMH seen in posterior reversible encephalopathy syndrome are, as the name suggests, posteriorly based. Acute demyelinating encephalomyelitis produces WMH, but they are seen both supra and infratentorially. Finally, vasculitides and infectious causes of WMH are numerous, but the findings are asymmetric and the diagnosis generally can be made by clinical presentation and simple laboratory analysis.



Summary/Conclusion
CADASIL remains elusive, as its symptomatology is nonspecific, but neuroimaging is paramount in its diagnosis. While genetic testing remains the gold standard and neuroimaging cannot make the diagnosis alone, characteristic MRI findings of CADASIL are relatively specific: symmetric T2-weighted and FLAIR hyperintensity in the white matter of the anterior temporal lobes and external capsules suggests a diagnosis of CADASIL.

KEYWORDS: MR imaging brain, White matter disease, CADASIL

EdE-05

Inadvertent Reset of a Programmable Cerebrospinal Fluid Shunt: Not Just a Theoretical Concern

Hira, A. S.·Macyszyn, L.·Mamourian, A.
University of Pennsylvania
Philadelphia, PA.

Purpose
Programmable ventriculoperitioneal shunt valves are used widely and represent an important tool for the treatment of both adult and pediatric cases of hydrocephalus. While inadvertent resetting of the magnetic valve due to an MR scanner's magnetic field has been suggested to offer a potential risk, there are no such cases reported in the literature. We present two such cases of MR scan-programmable shunt interaction to emphasize this risk in the MR environment.
Approach/Methods
We reviewed the literature regarding inadvertent magnet interaction and the recognition of programmable shunt valves. Two patients in whom their programmable valve settings changed during an MRI examination were identified retrospectively from our institution and reported here.
Findings/Discussion
Recent studies have demonstrated improved long-term effectiveness of programmable valves for the treatment of hydrocephalus compared with conventional fixed valves. Balancing any benefit, however, programmable valves represent a new risk for patients having an MRI. It is essential that these valves be recognized prior to the scan and the valve settings interrogated afterwards so that any change can be communicated promptly to the patient's physician. In this report, the setting of one patient's Strata valve was altered from 0.5 to 2.5 due to their MR scan. While this change was in fact recognized by the radiologist no action was taken. The patient's ventricular system subsequently enlarged sufficiently to cause a change in mental status that required hospital admission. In a second patient with a programmable shunt, a striking change in the ventricular size was noted between the start and finish of a single MRI examination of the brain. Recognition of this change led to an immediate valve reset by neurosurgery staff.
Summary/Conclusion
Due to the increasing use of programmable VP shunt valves, it is essential for radiologists and MR staff to develop a system to identify such patients, check postscan settings, and make appropriate arrangements when reset is necessary. We provide these two cases to illustrate that this is not a theoretical problem and suspect that this situation is either underreported or unrecognized at some sites.

EdE-06

Hypertrophic Olivary Degeneration: Review of Anatomy, Pathology, and Imaging

Ahmed, F. Y.·Telford, R.·Roberson, G. H.·Vattoth, S.
University of Alabama
Birmingham, AL.

Purpose
The aim of this presentation is to review the anatomy of dento-rubro-olivary pathway, the so called "Guillain-Mollaret Triangle", and discuss how lesions in its afferent fibers lead to hypertrophic olivary degeneration (HOD). Our teaching point is to learn how to diagnose HOD according to its MRI appearance, and differentiate it from other medullary lesions in order to avoid unnecessary concern and intervention.
Approach/Methods
The presentation will be organized anatomically by dento-rubro-olivary pathway and adjacent structures with the help of MRI images and graphic representation. Hypertrophic olivary degeneration MRI appearance as well as laterality, and location of lesions causing it also will be discussed. Finally, special emphasis will be made on other medullary lesions which could be misdiagnosed as HOD.
Findings/Discussion
Hypertrophic olivary gegeneration is a unique type of transneural degeneration. It is caused by primary lesions in dento-rubro-olivary pathway. The inferior olivary nucleus (ION) hypertrophy may lead to misdiagnosis of HOD as a medullary mass lesion. Hypertrophic olivary degeneration could be ipsilateral, contralateral or bilateral based on the location of primary lesion and usually present at six months or later from having the primary lesion. Understanding the anatomy of "Guillain-Mollaret Triangle" and its clinical and radiologic implication is very important to diagnose HOD and differentiating it from other medullary lesions.
Summary/Conclusion
Diagnosis of HOD is to be considered in patient with dento-rubro-olivary pathway lesions. It is also important to know the differentiation between HOD and other medullary lesions. Correct diagnosis is crucial to avoid unnecessary investigations and clinical concern. At the end of this review, the radiologist will be confident in diagnosing HOD based on the understanding of underlying anatomy and its characteristic MRI appearance.

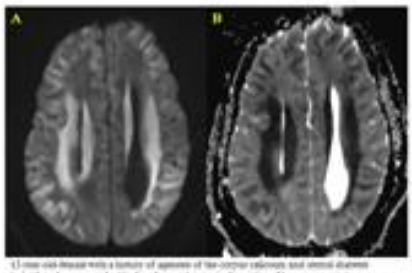
EdE-07

MR Imaging of Toxic and Metabolic Encephalopathies

Goldstein, A.·Samim, M.·Mahajan, A.
Yale University School of Medicine
New Haven, CT.

Purpose
Altered mental status is common in both the emergency and inpatient setting, ranging from confusion to coma. Initial workup often seeks to exclude catastrophic events such as stroke, infection/sepsis, and traumatic injury. Once these causes have been ruled out, a "secondary survey" usually includes an evaluation for toxic and metabolic etiologies, including drug intoxication, electrolyte abnormalities, hypoxemia, and uremia. In these conditions, noncontrast head CT can be nonspecific or unremarkable, and characteristic MR imaging findings may be helpful in narrowing the differential diagnosis. Since toxic-metabolic encephalopathies may be reversible, timely detection can help the referring clinician initiate early treatment to prevent further or permanent neurologic dysfunction. This educational exhibit reviews the MRI features of several more common toxic and metabolic encephalopathies to help the interpreting radiologist further contribute to the care of patients with such conditions.
Approach/Methods
This exhibit utilizes multisequential MR images from patients with clinical and laboratory findings consistent with specific metabolic and toxic encephalopathy syndromes to review their classic MR imaging features. Conditions to be discussed include hypoglycemia, hyperammonemia, hypernatremia, osmotic myelinolysis, and hyperalimentation, among others. Differences in the topographic distribution of signal abnormalities will be highlighted with a special emphasis placed on the underlying pathophysiology of the observed signal changes. Disorders with similar imaging findings will be compared and contrasted.
Findings/Discussion
Since various toxic and metabolic insults primarily affect different parts of the brain, specific imaging findings can suggest a diagnosis (or at least help narrow the differential diagnosis). For example, acute hyperammonemic encephalopathy typically results in T2 and FLAIR hyperintensities involving the insular cortex and cingulate gyrus, often with restricted diffusion. Osmotic demyelination classically involves the pons, as well as the cerebral white matter and basal ganglia, with hyperintense T2 and FLAIR lesions and possible restricted diffusion due to cytotoxic edema. Such imaging findings will be exemplified and further discussed in the exhibit.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Summary/Conclusion
The diagnosis of toxic-metabolic encephalopathy often poses a difficult clinical challenge. While history and physical examination findings can be suggestive, MR imaging can be of further assistance when classic imaging findings are present and recognized by the interpreting radiologist. An understanding of the basic patterns of cortical, white matter, basal ganglia, thalamic, and brainstem involvement by specific toxic-metabolic encephalopathies can narrow the differential diagnosis. In turn, this can prevent unnecessary testing, expedite treatment, and aid in providing prognostic information.

EdE-08

Asymptomatic Focal Cortical Dysplasia: An Underreported Entity?

Butteriss, D. J. A.[1]·Joshi, A.[2]
[1]Regional Neurosciences Centre, Newcastle upon Tyne, UNITED KINGDOM, [2]Royal Victoria Infirmary, Newcastle upon Tyne, UNITED KINGDOM.

Purpose
Focal cortical dysplasia (FCD) is an increasingly important entity due to its association with intractable epilepsy. With improvements in imaging and surgical techniques, lesional surgery may be an appropriate treatment for some cases of epilepsy related to an underlying FCD. However, it remains unclear what proportion of FCDs are asymptomatic. A single neuroradiologist in a single setting has found a series of seven cases of cortical and subcortical lesions suggestive of an atypical or novel form of FCD not associated with intractable epilepsy. These lesions have been investigated as low grade neoplasms, with unnecessary anxiety and investigation, up to and including brain biopsy. This document will review the imaging and clinical features of these cases.
Approach/Methods
Since August 2008 the author has collected seven cases with similar appearances from an unselected cohort of patients referred to the regions neurosciences center for imaging. Initial radiologic diagnoses for the abnormalities included infarct and low-grade glioma. In one case the lesion was not reported and in another the lesion was described and no differential diagnosis was offered. Only one case was offered a primary diagnosis of focal cortical dysplasia, as it was reported by the author while collating this data. The majority of lesions seemed to be incidental findings. In only one case was the patient being investigated for epilepsy (case 5 WP). In this case the patient had had a first seizure at the age of 59, while on holiday, and had imaging in Greece, not available for review. The report was of an infarct. The seizures were controlled with standard anti-epilepsy medication.
Findings/Discussion
All of the lesions have a similar appearance, being increased T2 and low T1 signal, centered on the subcortical white matter, sometimes with involvement of the overlying cortex. The lesions have a typical "bubbly" or "spotty" appearance around the periphery. The findings typically associated with FCD including thickening of the cortex, indistinct gray/white matter interface and trans-mantle signal change, are not apparent in these cases.

Patient ID	DoB	Sex	Date of initial MRI	Reason for scan	Lesion location	special sequences	Follow up	Histology
1 JW	11.06.58	F	16.08.11	Headache	RT temporal	DWI – unrestricted MRS – high CHO low NAA Non-enhancing	1 year No change	
2 MO	16.05.66	F	29.01.08	LT SO myokymia	RT parietal	MRS elevated CHO, low NAA FA- decreased Non-enhancing	2.5 years No change	FCD
3 JM	25.04.53	F	14.11.09	SNHL	RT parietal	SWI – large vein assoc FA – decreased ASL - isoperfused	2.5 years No change	
4 DS	16.07.31	M	16.11.11	Encephalitis	LT temporal	DWI- unrestricted Non enhancing	6 months No change	
5 WP	23.07.47	M	05.08.06	New onset seizures	RT frontal	T2* - normal DWI –unrestricted Non-enhancing	6 years No change	Hamartoma/ dysplasia
6 RW	08.06.44	M	10.07.12	Cognitive decline	RT frontal	T2* - normal		
7 LL	26.11.55	F	12.05.07	Meningioma	RT posterior temporal	Non-enhancing	5.5 years No change	

Summary/Conclusion
The spectrum of focal cortical dysplasia may be larger than previously thought, with asymptomatic cases with a novel, but typical appearance being relatively common. These cases should and can be identified early so patients can be appropriately counselled, without need for extensive, expensive and invasive investigation.

KEYWORDS: Focal cortical dysplasia, asymptomatic

EdE-09

Adult Manifestations of Congenital Pediatric Brain Disorders

Reilly, C. B.·Tantiwongkosi, B.
University of Texas Health Science Center at San Antonio San Antonio, TX.

Purpose
Adult neuroradiologists may be unfamiliar with the imaging manifestations of pediatric brain insults presented

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

in adulthood. The aim of this exhibit is to review adult manifestations of select common and uncommon congenital brain disorders, and how their radiologic appearance may be similar or different from a pediatric population.
Approach/Methods
Several cases of known or suspected congenital or acquired pediatric brain pathologies seen in the adult population on CT and MR examinations at our tertiary care academic institution over the last several years were selected for presentation. We performed a review of the literature to guide discussion of radiologic findings and the similarities and differences between adult and pediatric populations. When available, clinical pictures are presented to correlate with the imaging findings.
Findings/Discussion
We present a selection of cases collected from our institution of adult patients presenting with pediatric brain pathologies. Developmental brain disorders presented include Chiari malformation, neuronal migrational anomaly, posterior fossa malformation, etc. Some pediatric patients having toxic metabolic disorders survive till their adulthood with residual brain findings including hypoxic ischemic encephalopathy, adrenoleukodystrophy, mitochondrial diseases, etc. Neurocutaneous syndromes presented include neurofibromatosis, tuberous sclerosis, von Hippel-Lindau disease, and Sturge Weber syndrome. We discuss these conditions with an emphasis on appearance in the adult population and similarities and differences between the appearances in a pediatric population. Embryologic and pathologic basis of the diseases are discussed.
Summary/Conclusion
This exhibit demonstrates adult manifestations of pediatric brain diseases. For each of the conditions encountered, a relevant differential diagnosis is provided and the pertinent differences and similarities in imaging findings when encountered in pediatric versus adult populations are provided. We hope to provide a concise review and discussion after which the reviewer will feel more comfortable when encountering this selection of pediatric neurologic conditions when discovered in an adult population.

KEYWORDS: Congenital anomalies, Metabolic, neurocutaneous syndromes

Hippocampal Changes in Seizure and Status Epilepticus: The Spectrum of Findings You Need to Know

Sanghvi, T. S.·Young, S. J.·Patel, S. T.·Quisling, R. G.
University of Florida
Gainesville, FL.

Purpose
Evaluation of the hippocampus in the context of a recent seizure event (not known epilepsy) requires an understanding of the specific structures that make up the hippocampus. We will begin with a review of the relevant anatomy and subsequently describe abnormal hippocampal findings.
Approach/Methods
To call an exam normal one needs to identify all of the specific structures within norma- sized hippocampi. We will begin by reviewing critical anatomy, describing the specific internal locations of the major (pyramidal) cell bodies and the myelinated pathways, as well as describe structures such as the entorhinal cortex, dentate granular layer, mossy fiber region within the hilum of the hippocampus, the conru amonis (especially CA3 and CA1) and finally the subiculum. Details of these structures are presented on both anatomical and MRI images. Once normal anatomy is reviewed we will focus on the spectrum of hippocampal abnormalities seen with acute temporal lobe seizures correlated with animal modeling for status epilepticus.
Findings/Discussion
Once normal findings have been described we will describe the time dependent changes seen with temporal lobe epilepsy. Hippocampal injury during limbic seizure activity undergoes a process similar to that of an ischemic event and follows a similar evolution of the glutamate cascade. Thus, the severity of findings match the depth and duration of the ictus event. The hyperacute stage includes hippocampal edema and effacement of the internal white matter lamination. The range of acute and subacute findings extending to chronic mesial temporal sclerosis also will be discussed.
Summary/Conclusion
The consequence of untreated prolonged seizures and subclinical status epilepticus is often dire. The need to make the diagnosis quickly and accurately enables the clinical service to treat effectively. In order to make the diagnosis quickly and accurately the radiologist must first be familiar with normal hippocampal anatomy so that he/she may recognize the presented spectrum of abnormalities. This presentation hopefully will increase awareness of subtle abnormalities and increase confidence in reporting which may result in significant clinical implications.

Interpretation and Pitfalls in 18-F Florbetapir Imaging for the Evaluation of Dementia of the Alzheimer Type: A Pictorial Essay

Pamarthy, S.[1]·Bohnen, N. I.[1,2]·Gross, M. D.[2]·Fig, L. M.[2]
[1]University of Michigan, Ann Arbor, MI, [2]Department of Veterans Affairs, Ann Arbor Healthcare System, Ann Arbor, MI.

Purpose
18-F Florbetapir (Amyvid) was recently (April 2012)

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

approved by the Food and Drug Administration (FDA) for imaging of patients with cognitive impairment who are being evaluated for dementia of the Alzheimer type (DAT) versus alternative etiologies of cognitive decline. The agent binds with high affinity to neuritic β-amyloid plaques and is used to estimate plaque density. Image interpretation, which should be performed only following the completion of the FDA-required company-sponsored training program, differs from that of conventional radionuclide brain imaging, and requires binary categorization of images as positive or negative. We review the methodology for image acquisition and the interpretative schema for 18-F florbetapir studies as an introduction for radiologists who may be contemplating the use of this agent.

Approach/Methods

This educational exhibit will: 1. Describe technical aspects of 18-F Florbetapir PET imaging; 2. Using multiple images, discuss the interpretative criteria for positive and negative scans and the clinical significance of each; 3. Demonstrate the limitations of the use of 18-F Florbetapir imaging and the interpretative pitfalls that may be encountered.

Findings/Discussion

The exhibit will detail important aspects of the imaging protocol, including dosage, timing, PET scan acquisition and processing. Case examples will demonstrate positive and negative florbetapir images; this determination depends on assessment of the gray to white matter contrast. It is important to note that a positive scan, while indicating moderate to frequent amyloid plaques does not unequivocally establish a diagnosis of DAT because positive scans also may be observed in the cognitively normal aging brain (as confirmed by neuropathologic investigation), and in patients with other neurologic diagnoses (e.g., dementia with Lewy bodies). On the other hand, a negative florbetapir scan indicating the absence (or rarity) of neuritic plaques is inconsistent with a current diagnosis of DAT. To date, florbetapir imaging is not clinically indicated in predicting future dementia or for monitoring therapeutic response. Difficulties in interpretation may be related to cortical atrophy leading to widening of the sulci with consequent reduction of gray to white matter contrast, other structures that may take up the tracer (e.g., salivary glands), suboptimal image quality and artifacts such as patient motion.

Summary/Conclusion

18-F Florbetapir PET imaging is now FDA approved for the evaluation of selected patients with cognitive impairment. This exhibit may help improve the neuroradiologist's understanding of the techniques, interpretation methods, and limitations of the test to more effectively guide referring clinicians in its appropriate use in suitable patients.

KEYWORDS: Alzheimer disease, PET, 18-F Florbetapir

EdE-12

FDG-PET Neuroimaging of Medically Refractory Epilepsy: An Illustrative Review

Thaker, A. A.·Dubroff, J. G.
Hospital of the University of Pennsylvania
Philadelphia, PA.

Purpose

Neuroimaging studies play an established role in the diagnosis and evaluation of epilepsy, particularly in patients with medically refractory temporal lobe epilepsy (TLE). While MRI is highly sensitive and specific for hippocampal sclerosis (HS), the most common pathologic basis of TLE, a limited but significant number of patients have no identifiable MRI lesion. F-18 flourodeoxyglucose positron emission tomography (FDG-PET) is an adjunct imaging modality which often reveals ipsilateral hypometabolism, which has been shown to predict a good prognosis post-temporal lobectomy. The purpose of this educational exhibit is to provide an illustrative review of the role of FDG-PET neuroimaging in the evaluation of patients with medically refractory TLE.

Approach/Methods

Epilepsy surgery in patients with refractory TLE is a well established and evidence-based treatment. High-resolution MRI plays a crucial role in identifying potential epileptogenic lesions, and is the initial imaging modality in these patients. This exhibit will first present typical case examples of mesial temporal sclerosis (MTS), the MRI correlate for HS, with side-by-side FDG-PET comparison, which often demonstrates concordant focal hypometabolism (MRI+/PET+ cases). Approximately 15-20% of patients with refractory TLE have no MRI abnormality, and many of these patients will have only asymmetric focal hypometabolism on interictal FDG-PET. A case series of these MRI-/PET+ patients will be presented with additional relevant clinical data, including postsurgical outcome by Engel class. Finally, case examples of TLE patients with MTS on MRI and normal brain FDG-PET will be presented (MRI+/PET-).

Findings/Discussion

In epileptic patients with disease refractory to drug therapy, the main aim of surgery is seizure control and thus improved quality of life. Postsurgical outcomes are stratified by Engel class (class I: free of disabling seizures, class II: rare disabling seizures, class III: worthwhile improvement, class IV: no worthwhile improvement). Several published case series have shown that patients with intractable TLE and MRI-/PET+ have no difference in surgical outcome than those patients with MRI+ mesial temporal sclerosis. This data will be referenced in this exhibit to underscore the important adjunct role of FDG-PET in intractable TLE patients (see case example in Figure 1).

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

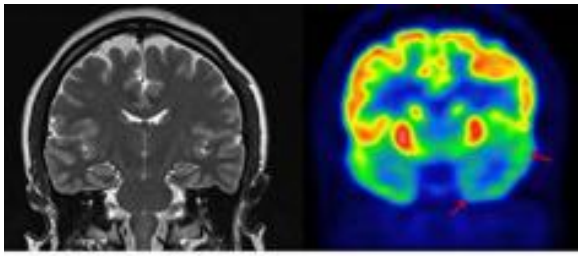

Figure 1.

Summary/Conclusion
FDG-PET neuroimaging has an increasing role in the presurgical evaluation of medically refractory TLE patients, and has been shown to identify patients who will have good surgical outcomes, regardless of whether MTS is identified on MRI. FDG-PET is an important modality in the armamentarium of the neuroradiologist who evaluates epilepsy patients.

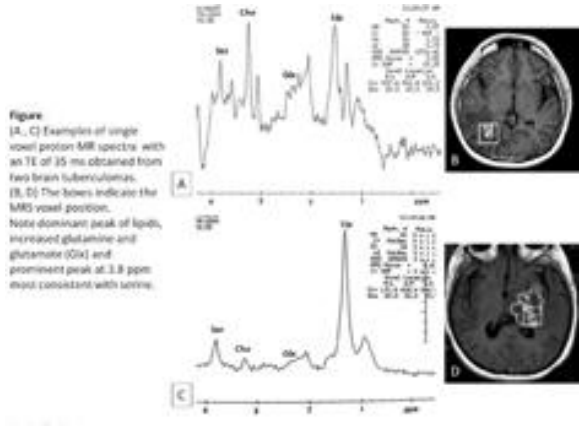
EdE-13

MR Spectroscopy of Brain Tuberculomas: Findings and Literature Review

Morales, H.[1]·Gaskill-Shipley, M.[1]·Alfaro, D.[2]·Martinot, C.[3]·Castillo, M.[4]
[1]University of Cincinnati, Cincinnati, OH, [2]University Nacional Mayor de San Marcos, Lima, PERU, [3]Centro de Resonancia Magnetica, Lima, PERU, [4]University of North Carolina at Chapel Hill, Chapel Hill, NC.

Purpose
Central nervous system tuberculosis (TB) is a major health concern in developing countries, and is increasing in developed countries due to HIV/AIDS and multidrug-resistance. Our purpose is to describe the most common MR spectroscopic (MRS) findings in brain tuberculomas.
Approach/Methods
We describe the most common MRS findings in brain tuberculomas. Thirteen proven cases by histology and/or response to antimycobacterial therapy will be used to demonstrate the findings. The metabolic alterations are discussed in correlation with possible pathologic mechanisms, recent literature and spectroscopic findings of other common brain masses such as gliomas.
Findings/Discussion
Brain tuberculomas show a dominant peak of lipids. Most demonstrate an increase in glutamate/glutamine (Glx) and a serine peak at 3.8 ppm. Increased choline (Cho) is more common than previously thought. The presence of serine and lipids correlate with the make-up of the mycobacterium cell wall. Increased Glx is not a common finding in gliomas, its presence along with serine favors TB.



Figure

Summary/Conclusion
In absence of lipids, the diagnosis of brain tuberculoma is unlikely.

KEYWORDS: MR spectrocopy, Tuberculosis

EdE-14

Pictorial Review of the Various Clinical, Radiologic and Pathologic Findings of Chronic Lymphocytic Inflammation with Pontine Perivascular Enhancement Responsive to Steroids

Bhatnagar, P.·Karsandas, A.·Hall, J.·Birchall, D.·Butteriss, D.
Royal Victoria Infirmary
Newcastle upon Tyne, UNITED KINGDOM.

Purpose
1. To present the clinical and imaging findings of chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS). 2. To aid better understanding of the pathogenesis and the histopathological findings of CLIPPERS. 3. To review the literature and enable the neuroradiologists in making the correct diagnosis.
Approach/Methods
Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids recently has been proposed as a rare chronic inflammatory central nervous system disorder which has a predilection to hindbrain and responds to immunosuppressive therapy. We present four cases encountered recently at our institution. Detailed laboratory workup and brain biopsy were performed. We describe the clinical features and MRI appearances of these cases. We also review the clinical and radiologic response to steroids. A brief differential diagnosis and review of literature will be presented.
Findings/Discussion
Patients with CLIPPERS mainly presented with ataxia, nystagmus, diplopia. MR imaging demonstrated characteristic pattern of punctate and curvilinear enhancement peppering the pons and extending variably into the medulla, brachium pontis and mid-brain. Lesions

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

are typically less numerous and smaller as distance from the pons increases. One patient had involvement of the spinal cord, which has been described in literature. Lesions show patchy nonspecific increased T2 signal in the corresponding areas of contrast enhancement. The lesions do not have significant mass effect. Differential diagnoses that need to be considered and excluded include: neurosarcoidosis, lymphoma, vasculitis, Bickerstaff brainstem encephalitis, Bechet's, paraneoplastic and demyelinating diseases. On histopathology, there is marked lymphocytic infiltrate in the white matter with perivascular predominance and also a more diffuse parenchymal inflammatory infiltrate. Treatment with steroids leads to marked improvement with rapid improvement on the MRI. Rarely, cyclophosphamide is required for immunosuppression. Marked cerebellar atrophy often results and may contribute to long-term neurologic morbidity.

Summary/Conclusion

Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids is a newly described distinct inflammatory CNS disorder and probably more frequent than previously thought. It has characteristic MRI findings and there may be extrapontine involvement. Better understanding of this condition will enable the neuroradiologists in making a prompt diagnosis. This will help effective management, which may in turn limit permanent neurologic sequelae.

EdE-15

Pictorial Review and Differential Diagnosis of Common Choroid Plexus Lesions

Barret, W. A.[1]·Gaddamanugu, S.[2]·Vattoth, S.[1]
[1]University of Alabama Birmingham Radiology, Birmingham, AL, [2]Veterans Affairs Hospital, Birmingham, Birmingham, AL.

Purpose

Choroid plexus are present throughout the ventricles, but are most prominent in the body of the lateral ventricles. They are highly vascularized enhancing structures. Lesions involving the choroid plexus are diverse. The purpose of this exhibit is to review common choroid plexus pathology and to described imaging features which characterize and differentiate benign lesions from more malignant or obstructing pathology.

Approach/Methods

Anatomy and pathologies involving the choroid plexus will be reviewed. Computerized tomography and magnetic resonance images of choroid plexus pathologies will be illustrated. Imaging findings which help characterization of individual pathologies will be detailed.

Findings/Discussion

Pathology involving the choroid plexus is rare. The choroid plexus may be involved in systemic/generalized neurologic conditions or focally by tumors or cysts. The most common pathology involving the choroid plexus in adults are incidental simple or xanthogranulomatous cysts. The choroid plexus also can be involved by meningioma, metastasis, vascular malformations or lipoma. Temporal lobe surgery can alter choroid plexus morphology. In children or infants, the most common abnormality involving often is choroid plexus cysts or hemorrhage. Other rare pathology include choroid plexus papilloma or carcinoma. The choroid plexus can be secondarily involved in patients with syndromic disorders such as Sturge-Weber syndrome.

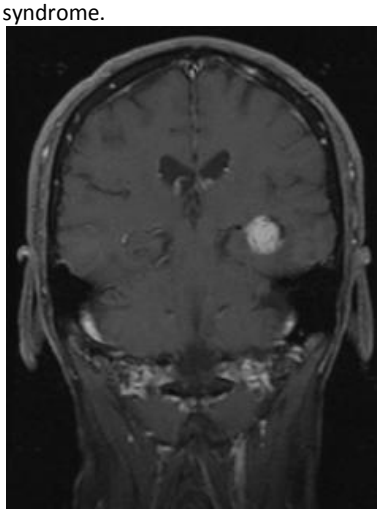

Image 1: Axial T2-weighted image of the brain reveals enlarged choroid plexus of the left temporal horn.

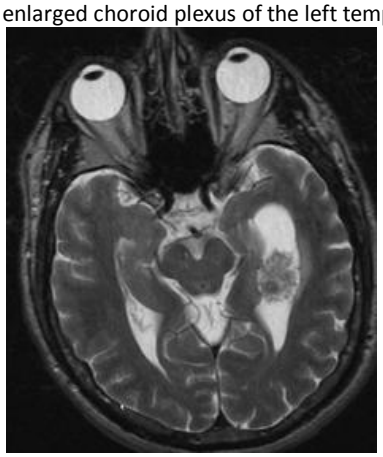

Image 2: Postcontrast images reveal significant enhancement of the choroid plexus mass. Patient had thyroid cancer and a iodine-131 posttreatment scan which revealed intense uptake in the left lateral ventricle, consistent with metastasis.

Summary/Conclusion

Knowledge of common incidental choroid plexus pathology is essential to avoid necessary investigations. More serious pathology of the choroid plexus is rare. This exhibit will review the common pathologies involving the choroid plexus.

KEYWORDS: Choroid plexus, Ventricles

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

EdE-16

Extreme Pseudoprogression on MR Imaging of High-Grade Gliomas Treated with Paclitaxel Poliglumex: Comparison with Conventional Pseudoprogression and True Tumor Progression

Farnam, J.·Boxerman, J.·Jeyapalan, S.·Elinzano, H.·Goldman, M.·Safran, H.
Brown University Alpert School of Medicine
Providence, RI.

Purpose
High-grade gliomas (HGG) are the most common primary brain malignancies, with glioblastoma multiforme having a particularly dismal overall survival. Conventional first-line treatment includes resection plus targeted radiation in combination with chemotherapy. Chemoradiation with the radiosensitizing agent temzolomide (TMZ) has been associated with *pseudoprogression*, defined as progressive MRI enhancement following therapy that stabilizes or resolves over time without treatment modification. Paclitaxel poliglumex (PPX), a radiosensitizing agent previously investigated for treatment of esophageal cancer and more recently applied to the treatment of high-grade gliomas, has a radiosensitizing index 4-8 times that of TMZ and may similarly incite pseudoprogressive enhancement on post-treatment MRI examinations but to a much greater degree, and with durations exceeding that typically seen with TMZ. We aim to present examples of pseudoprogression with both agents, emphasizing the similar and distinguishing features, as well as examples demonstrating the similar appearance of true tumor progression.
Approach/Methods
A recent phase II study evaluated progression-free survival of patients with HGG treated with radiation and both PPX and TMZ. We will present the serial MR imaging of multiple patients from this study, demonstrating a spectrum of pseudoprogression and true tumor progression and compare this to examples of true progression and pseudoprogression in patients with HGG treated with TMZ and radiation therapy alone.
Findings/Discussion
Twenty-five patients were included in the above-mentioned study, 13 with post-PPX MRI findings consistent with pseudoprogression. Pathologic correlation with biopsy or repeat surgery was obtained in five of these patients. Onset of pseudoprogression occurred 2 to 174 days (mean 63 days) following completion of PPX, and persisted 18 to 719 days (mean 334 days). This “extreme” *pseudoprogression* persisted significantly longer than that typically seen with TMZ and radiation therapy alone. Pseudoprogression very closely resembles true tumor progression in appearance on postcontrast T1-weighted images.

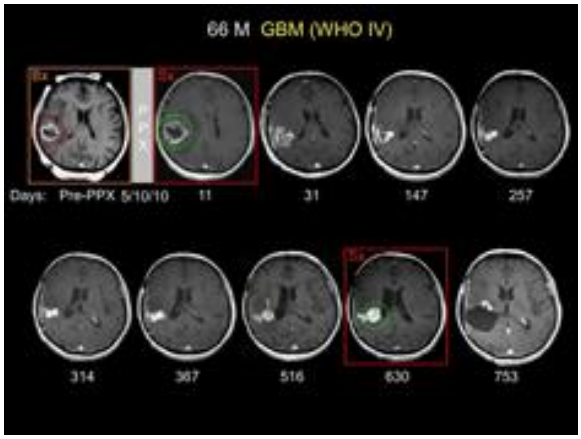

Figure 1. Extreme *pseudoprogression* with combined PPX/TMZ chemoradiation. Surgical excision at 630 days.
Summary/Conclusion
Pseudoprogression has been demonstrated in the setting of chemoradiation with combined PPX+TMZ with MRI findings that are more extensive and longer lasting than those seen with conventional radiosensitizing agents. Higher radiation sensitizers can therefore produce post-treatment imaging that appears increasingly worrisome to the neuroradialogist. Knowledge of the specific chemotherapeutic regimen therefore is essential when interpreting follow-up imaging and evaluating treatment response so as to not erroneously assume the presence of tumor progression. This will likely remain relevant to the neuroradiologist as additional highly radiation sensitizing agents are introduced clinically.

KEYWORDS: Pseudoprogression, Glioblastoma, paclitaxel poliglumex

EdE-17

Laser Interstitial Thermal Therapy for Brain Neoplasms: Imaging of Treatment Changes with Clinical Correlation

Bagade, S.[1]·Miller-Thomas, M.[1]·Mettenberg, J.[1]·Hawasli, A.[2]·Shimony, J.[1]·Leuthardt, E.[2]
[1]Mallinckrodt Institute of Radiology, St. Louis, MO, [2]Barnes Jewish Hospital, St. Louis, MO.

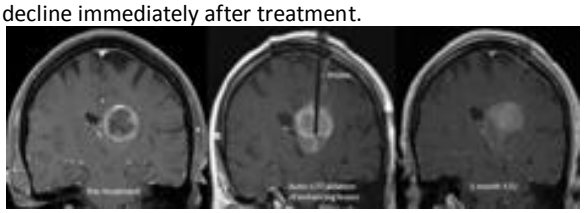
Purpose
1. To introduce the laser interstitial thermal therapy (LITT) technique to the neuroradiology community. 2. To report intraoperative, early and late post-treatment MRI findings in patients undergoing thermal ablation using LITT for brain tumors. 3. To review clinical outcome following the procedure.
Approach/Methods
A total of 15 patients with malignant brain neoplasms treated with thermal ablation using Monteris AutoLITT system at our institution were included in the study. Subjects included six females, nine males with ages between 34 to 78 years. These patients either had lesions

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

not amenable to surgical resection or had medical comorbidities precluding traditional surgical treatment. Ten patients had primary glial neoplasms including glioblastoma multiforme (GBM) in five patients, high-grade astrocytoma in four patients and oligodendroglioma in one patient. The remaining five patients had metastatic brain lesions; three from lung carcinoma and one each from melanoma and colorectal cancer. One patient with GBM received repeat ablation of a lesion which had exhibited growth over 10 months in followup. A retrospective review of pre, intra, and postoperative imaging of these patients was performed, making note of volume of the enhancing tumor, presence of hemorrhage, necrosis, and extent of perilesional T2/FLAIR signal on imaging before and after ablation. Clinical outcome during the postoperative course was noted.

Findings/Discussion

On postoperative imaging, treated lesions showed increased T1 signal and susceptibility on blood-sensitive sequences consistent with hemorrhage and/or protein from coagulative necrosis. There was a surrounding new thin uniform rim of contrast enhancement following ablation. Most lesions showed mildly increased surrounding T2/FLAIR signal in the early postoperative course which decreased on delayed imaging. Significant number of patients had decrease in diffusion restriction as well as decrease in size of the enhancing portions of the lesion. The time course of these findings is currently under investigation. Six of 15 patients currently remain stable and recurrence free. Eight patients have experienced disease progression or recurrence since surgery (mean, five months progression-free). One patient had a clinical decline immediately after treatment.



Summary/Conclusion

Laser interstitial thermal therapy is a minimally invasive treatment option for intracranial neoplasms to a subset of patients offering potentially decreased operative morbidity. Knowledge of imaging response to this treatment would be helpful to radiologists as this becomes a more commonly used neurosurgical treatment technique. Typical findings in the ablative zone include bright T1 signal with surrounding reactive ring enhancement accompanied by an initial increase in peritumoral edema which decreases later.

KEYWORDS: Neoplasm, Laser, laser interstitial thermal therapy

EdE-18

Illustrative Review of Cavernous Angiomas and their Variants

Meyer, M. A.·Shastri, R.·Shroff, S.·Khan, R.
University of Arizona
Tucson, AZ.

Purpose

To review the etiology/pathophysiology of sporadic and familial cavernous malformations and discuss the CT and MR imaging characteristics of cavernous malformations, including giant infiltrative cavernous malformation.

Approach/Methods

A literature review will be performed in order to accurately discuss the classification and various appearances of cavernous malformations. A pictorial essay of various appearances and classification of cavernous malformations will ensue.

Findings/Discussion

1. Introduction, 2. Pathogenesis and clinical manifestations of cavernous malformations, 3. Sporadic versus familial cavernous malformations, 4. CT and MR imaging characteristics, 5. Zambramski classification of cavernous malformations (with diagrams), 6. Associations and differential considerations.

Summary/Conclusion

At the end of this presentation, the viewer should be familiar with the unique and varied imaging appearance of cavernous malformations on both CT and MRI, their imaging classification system, mimicking lesions, as well as their natural history, pathogenesis, and clinical presentation. By reviewing the Zambramski classification as well as the varied etiology of these vascular malformations, the viewer will be better able to distinguish these lesions from arteriovenous malformations and hypervascular tumors.

KEYWORDS: Cavernous malformation, Zambramski classification

EdE-19

Plasmacytoma: Gamut of Neuroradiologic Imaging Findings

Marroquin, R.·Agarwal, A.
University of Missouri
Columbia, MO.

Purpose

To describe the spectrum of CT and MR imaging findings of solitary extramedullary and bone plasmacytomas in different locations related to neuroradiology.

Approach/Methods

Retrospective review of the imaging findings of all histopathologically proven cases of plasmacytomas from July 2009 until November 2012. A total of 11 cases were reviewed.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Findings**/**Discussion
Plasmacytoma is considered a counterpart of multiple myeloma that is described as a solitary and discrete mass of monocolonal neoplastic plasma cells found in either bone or soft tissue. Plasmacytomas are divided into two groups according to their location: solitary bone plasmacytoma (when found in the skeletal system) and extramedullary plasmacytoma (EMP). Isolated EMP is very rare and comprises less than 4% of all plasma cellular disease of which more than 80% are localized to the submucosal lymphoid tissue of the nasopharyngeal and paranasal sinuses. This review will focus most on EMP as those are extremely rare and represent a diagnostic challenge. We will demonstrate the imaging findings of 11 cases of histopathologically confirmed plasmacytoma in different locations related to neuroradiology. Five cases were found to be in relation to the spine of which one presented as an isolated epidural mass in the lumbar spine with no definite bony involvement. Six cases were found to be in the head and neck region, of which two cases presented primarily as a nasal cavity soft tissue mass. One patient presented as an isolated nasopharyngeal mass with parapharyngeal extension.

Summary/Conclusion
Extramedullary and solitary bone plasmacytoma shows nonspecific CT and MR imaging features. MR imaging is the preferred modality for evaluation due to better soft tissue contrast. Features that may suggest the diagnosis of plasmacytomas are a bulky soft-tissue mass or infiltrative lesion.

KEYWORDS: Plasmacytoma, Brain neoplasms

EdE-20

Purpose of this Educational Exhibit is to Illustrate the MR Imaging Findings of Paraneoplastic Neurologic Syndromes, and Discuss the Clinical Manifestations of these Disease Entities

Bagga, S.·Eskey, C.·Fadul, C.
Dartmouth Hitchcock Medical Center
Lebanon, NH.

Purpose
Paraneoplastic neurologic syndromes (PNS) are remote effects of cancer that are not caused by the primary cancer or metastasis, or by infection, ischemia or metabolic disoders. These syndromes are being recognized more frequently because of longer patient survival, improved immunologic testing and use of advanced neuroimaging and improved knowledge amongst physicians. The neurologic disorder may develop before the cancer manifests clinically
Approach/Methods
This educational exhibit will discuss the clinical presentations, diagnostic testing including MRI imaging used for making the diagnosis of PNS.
Findings/Discussion
Some PNS are associated with antibodies directed against antigens expressed by both the tumor and the nervous system (onconeural antibodies). This association favors immune-mediation. However, the inability to find such antibodies does not rule out the diagnosis. The presence or the absence of paraneoplastic antibodies and the type of antibodies define different subtypes of PNS. Limbic encephalitis, subacute cerebellar ataxia, opsoclonus-myoclonus, retinopathies, sensory neuropathy, Lambert-Eaton myasthenic syndrome, Stiff-person syndrome are the most common syndromes.
Summary/Conclusion
The clinical manifestation and imaging findings of PNS will be reviewed.

KEYWORDS: Paraneoplastic, Encephalitis

Extracranial Manifestations of Glioblastoma: Thinking Outside the Box

Ginat, D.·Timpone, V.·Schaefer, P.
Massachusetts General Hospital
Boston, MA.

Purpose
To review the imaging manifestations of the various types

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

of extracranial glioblastomas.
Approach/Methods
Retrospective review of our institution imaging database identified 20 cases of extracranial glioblastoma metastases, including 14 cases of drop metastases, one case of continuous extension into the cervical spinal cord from a brainstem glioblastoma, two cases of direct extension across the craniotomy into the dura and extradural soft tissues, one case of seeding in scalp along the surgical approach from prior craniotomy, one case of tumor dissemination via a ventriculoperitoneal shunt, and one case of systemic metastases. In addition, we encountered one case of glioblastoma that arose in conjunction with primitive neuroectodermal tumor in the ovary.
Findings/Discussion
Extracranial gliobastomas are uncommon entities. Most of these occur as metastases from primary intracranial glioblastoma. Mechanisms of dissemination include CSF spread into the spinal canal, direct extension through a craniotomy defect into the dura, direct extension from the brainstem into the spinal cord, seeding into the scalp during surgery or via shunt catheter, lymphatic spread, and hematogenous spread. Alternatively, glioblastomas can arise occasionally as primary tumors outside the brain, such as within the spinal cord and can even arise within ovarian teratomas. Imaging approaches for the spectrum of extracranial glioblastoma manifestations are further reviewed in this exhibit.
Summary/Conclusion
There is a wide spectrum in which extracranial glioblastoma metastases can manifest. Nevertheless, these typically display similar imaging features as their intracranial counterparts. The possibility of metastases should be considered upon review of follow-up brain MRI and imaging of the spine in patients with known glioblastoma.

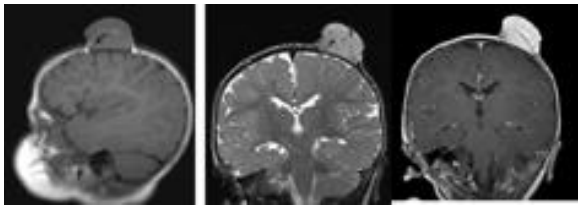
KEYWORDS: Glioblastoma

EdE-22

"*At the Top of My Head*" - Mutimodality Imaging of Focal Protruding Masses of the Scalp and Skull in Adults and Children: A Pictorial Review of Pathology Causing *Bumps on the Head*

George, M.[1,2]·Li, S.[1,2]
[1]Baystate Medical Center, Springfield, MA, [2]Tufts University Medical School, Boston, MA.

Purpose
Focal protruding masses at the top of the head can become very large and disfiguring. They may cause social embarrassment and psychologic disturbance in the diseased. There is a wide spectrum of pathology that can cause *Bumps on the Head.* However there is no simple way to organize this group of diverse entities. The purpose of this exhibit is: to illustrate the imaging findings and their underling pathology of each disease entity with discussion of their differential diagnosis; to describe the related clinical presentations, relevant anatomy and treatment options.
Approach/Methods
1. These focal protruding masses of the skull and scalp can be evaluated with a multimodality imaging approach. CT and MR are most common utilized tools. Plain X-ray films, ultrasound and nuclear medicine studies sometimes are used. 2. To discuss their clinical presentations, etiology, differential diagnosis and treatment of each entity; To develop an organized search pattern from an anatomical approach. 3. The spectrum of those *Bumps on the Head* is different in adults and children. The most common ones in each group are presented and discussed.
Findings/Discussion
Focal skull and scalp masses can affect people of different age, from the newborn to adults. They range from benign to malignant as well. In children, the disease entities more commonly include an encephalocele, epidermoid, eosinphilic granuloma, exostoses, a hemangioma, etc. In adults, the disease entities include focal matastasis, lipoma, meningioma, neurofibroma, etc. Their imaging examples are displayed. CT and MR are the main imaging tools. The related clinical presentations, underline pathology, differential diagnosis and clinical management are discussed.



Summary/Conclusion
Bumps on the head can be caused by a diversity of diseases. These etiologies may be benign or malignant, syndromic or sporadic, bony or soft tissue in origin. They also occur in patients of different age. Considering the degree of variability and a wide spectrum of pathology, a broad and methodical approach is required for accurate and assured diagnosis. At the end of the presentation, the viewers will: 1. Become familiar with the different causes of focal protruding masses of the scalp and skull in adults and children, their clinical presentations and imaging characteristics so as to aid the radiologist in making appropriate and timely diagnoses and guiding further management. 2. Form a focused differential diagnosis based on the patient's clinical history and the physical appearance. 3. Understand their clinical presentations and underline radiologic-pathologic correlations.

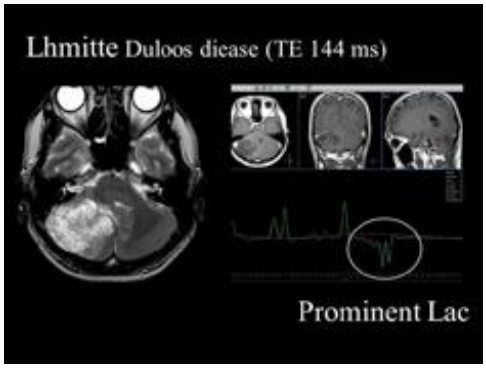
Pictorial Review of Various Diseases Causing Lactate Peak on MR Spectroscopy in Daily Practice

Nakamura, H.·Onodera, H.·Yoshida, Y.·Tanaka, Y.·Nakajima, Y.·Uchida, M.
St.Marianna University of Medicine
Kawasaki, JAPAN.

Purpose
The exhibit is to list the wide spectrum of diseases showing lactate peak and have enough knowledge about the etiology of lactate peak.
Approach/Methods
Although lactate cannot be resolved in the adult human brain under normal conditions, strongly enhanced concentrations of cerebral lactate often are seen in disease states associated with an increasing energy demand and/or impaired cellular capacity for oxidative phosphorylation. There are various conditions in which lactate peak can be resolved such as brain tumors, cerebral ischemia, demyelinating diseases and so on. For example in diagnosing brain tumor, lactate may be an indicator of malignancy, but it is not always true. Some benign brain tumors can show lactate peak. These confuse the radiologist. We reviewed retrospectively one thousand MR spectroscopy (MRS) and MRI studies from 2003-2012 and organized the information categorizing diseases according to the etiology.
Findings/Discussion
Lactate can be seen in the wide spectrum of diseases. These diseases include benign tumor (Lhermitte-Duclos diseases, pilocytic astrocytoma, desembroplastic neuroepithelial tumor) due to abnormal high glucose metabolism (glycolysis), malignant tumor (malignant lymphoma, metastatic tumor, high-grade glioma) due to both increased metabolic rate and the reduced clearance of lactate in the necrotic regions, radiation effect due to the ischemia underlying the mechanism for severe lesions, cerebral abscess due to the anerobic glycolysis of living cells, acute and subacute cerebral infarction due to anerobic glycolysis resulting from the decrease of oxygen supply, mitochondrial encephalopathy with lactic acidosis and stroke-like episodes (MELAS) and neonatal hypoxic encephalopathy due to the impairment of oxidative metabolism.



Summary/Conclusion
There are various diseases showing prominent lactate peak. It may be considered nonspecific but it is important to keep its variety in mind.

Imaging and Pathology Correlation of a Spectrum of Brain Tumors with Two Distinct Concomitant Pathologic Entities

Ramsewak, D.·Wang, A.·Patel, S.·Krishnan, A.·Donev, K.·Silbergleit, R.
Beaumont Health Systems
Royal Oak, MI.

Purpose
The occurrence of brain tumors with two different and distinct pathologic entities at the same location is rare, with only a few case reports in the literature. We aim to present four patients who harbored such "concomitant" or dual tumors, and review the neuroradiologic and pathologic findings.
Approach/Methods
Four pathology proven cases of concomitant brain tumors were identified and retrospectively reviewed. All of the patients had MR imaging of the brain performed with contrast. In addition, one of the patients also had MR spectroscopy and MR perfusion imaging. Corresponding pathology and related literature was reviewed.
Findings/Discussion
Two pathologically different tumors within the brain is a relatively rare occurrence; however, it is even more infrequent when the tumors arise simultaneously from the same location. Our four cases with such concomitant pathology include a glioblastoma occurring with a primitive neuroectordermal tumor (PNET), gliosarcoma occurring with a PNET, oligoastrocytoma occurring with metastatic B-cell lymphoma, and meningioma occurring with metastasis from lung adenocarcinoma. We also shall demonstrate the benefit of MR spectroscopy and MR perfusion in separating the two pathologies in the patient with the oligoastrocytoma and concomitant lymphoma.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

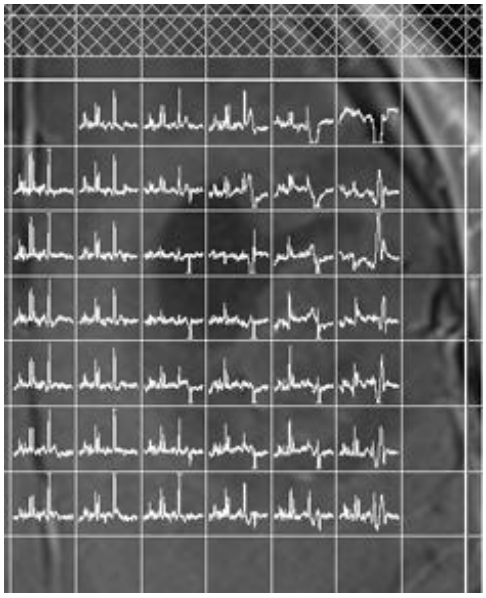

Figure 1. Multivoxel proton MR spectroscopy with TE 135 ms.

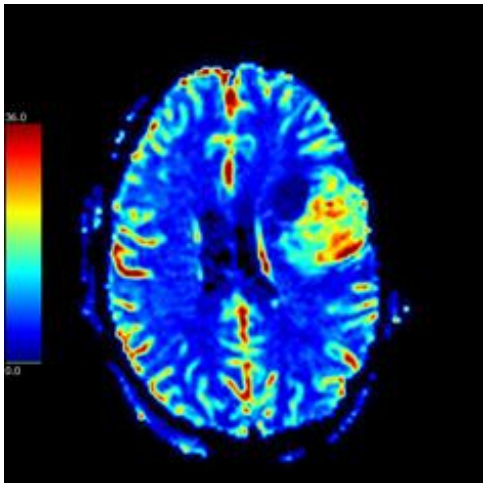

Figure 2. Dynamic contrast MR perfusion, show high malignant lymphoma with increased perfusion and increased choline peak contrasting with the concomitant oligoastrocytoma with decreased perfusion and decreased choline peak.

Summary/Conclusion

Brain tumors comprised of two distinct concomitant pathologic entities are rare and it is usually very difficult to determine the concomitant pathology from imaging findings alone. However, in our limited experience, MR perfusion and MR spectroscopy may help delineate different patterns within the tumor that correlate to their pathology.

Tour 3T Intraoperative MR Imaging for Brain Tumor Treatment

Ginat, D.[1]·Swearingen, B.[1]·Curry, W.[1]·Cahill, D.[1]·Madsen, J.[2]·Herrington, J.[1]·Schaefer, P.[1]
[1]Massachusetts General Hospital, Boston, MA, [2]Boston Childrens Hospital, Boston, MA.

Purpose

1) To describe the appropriate selection of intraoperative MRI protocols for glioma and pituitary tumor resection, thermoablation, and related technical considerations. 2) To depict the unique intraoperative MRI findings. 3) To review the benefits and shortcomings of intraoperative MRI for brain tumor surgery.

Approach/Methods

Intraoperative MRI is performed at 3T at our institutions. For enhancing brain parenchymal tumor surgery, the following sequences are implemented: • Sag T2 SPACE FLAIR, • Axial Diffusion, • Axial T2, • Sagittal T1 MPRAGE precontrast with fat suppression, • Sagittal T1 MPRAGE postcontrast with fat suppression. For nonenhancing brain parenchymal tumor surgery, the following sequences are implemented: • Sag T2 SPACE FLAIR, • Axial Diffusion, • Axial T2, • Sagittal T1 MPRAGE. For pituitary tumor surgery, the following sequences are implemented: • Axial T2, • Coronal T2, • Coronal T1, • Sagittal T1 precontrast, • Coronal T1 postcontrast with fat suppression, • Sagittal T1 postcontrast with fat suppression, MR thermography can be used to monitor thermoablation of brain tumors.

Findings/Discussion

Intraoperative MRI is a valuable resource that can be performed efficiently with the proper sequence selection. The literature and our experience suggest that intraoperative MRI increases the likelihood of gross total resection for both pituitary tumors and gliomas, which in turn has significant prognostic implications. The use of intraoperative MRI can provide more accurate guidance in the setting of brain shift compared to other image-guided methods. In addition, intraoperative MRI can detect unsuspected complications earlier than routine postoperative imaging, potentially leading to improved outcomes. A unique consideration in the interpretation of intraoperative MRI is the presence of hyperacute hemorrhage, which may be almost indiscernible on T1 MPRAGE, but mildly hyperintense on T2 FSE. Another distinctive phenomenon is the presence of contrast leakage during surgery, which can be a potential confounder for residual tumor. MR imaging thermometry using a phase-sensitive sequence can accurately delineate the effects MRI-guided interstitial thermotherapy of brain tumors in real time.

Summary/Conclusion

As intraoperative MRI is increasingly utilized for brain tumor resection, it is important to be familiar with optimal sequence selection and the unique imaging findings that may be encountered.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

EdE-26

Strategies to Mitigate the Risks of MR Imaging on Patients with Implanted Spinal Cord Stimulation Systems

Safriel, Y.[1,2]·Breitenfeldt, M.[3]·Mashhadi, O.[3]·Orser, H.[3]·Welter, J.[3]·Manker, S.[3]
[1]Pharmascan, Wilmington, DE, [2]University of South Florida, Clearwater, FL, [3]Medtronic, Minneapolis, MN.

Purpose
Approximately 70% of spinal cord stimulation (SCS) patients are expected to need at least one MRI over the expected life of the device. Safe MRI scanning of patients with some SCS systems is possible under certain conditions. However, radiologists may not be aware of product differences and existing MRI labeling. We provide an overview of potential risks when conducting MRI of patients with SCS systems (table) and discuss mitigation strategies related to two main risks associated with MR imaging of patients with SCS implantable systems.

Potential Interactions of MRI on SCS Systems in a Patient

Modality	Energy	Patient Effect	Concern	Solution/Guidance
Lead Heating	RF	Electrode heating in epidural space	Thermal damage at lead electrodes	Limit RF levels and exposure to the head with use of a transmit/receive head coil. Lead is outside the MRI imaging area and risk is mitigated
Unintentional Implanted Device Interactions	Static Gradient RF	Permanent damage to INS or device memory issues	Device explant or reprogramming required	Electromagnetic compatibility protection: circuitry such as FFTs or no magnetic reed switch in newer INS models
Unintentional Stimulation	Gradient RF	Uncomfortable stimulation or shocking	Patient discomfort	Turn the stimulator off. Limit gradient exposure to 20T/sec
Magnetic Pull	Static	INS movement in the pocket or lead movement	Pulling/tugging sensation on lead or INS	Minimal or no ferromagnetic material in INS or lead. Recommend suturing the INS
Device Heating	Gradient	INS heating	Warm sensation at INS site	Limit gradient exposure. Monitor patient
Vibration	Gradient Static	Device explant or uncomfortable vibration	Uncomfortable vibration or device damage	Limit gradient exposure to 20T/sec Minimize size of stimulator. Monitor patient

Approach/Methods
Predominant risks in MR scanning of patients with SCS devices are: 1. RF-induced lead heating resulting in thermal injury to the spinal column and 2. Gradient, RF and static-induced device damage. Both heating and device damage risks associated with Medtronic SCS system were evaluated in a phantom torso scanned with 1.5T MRI. Lead heating was tested using a body RF coil with the landmark centered over the phantom torso or a transmit/receive head coil with the landmark centered over the head of the phantom. Temperature increases were measured at four different probe sites as a function of time. Device damage testing was performed using a body RF coil with the system lead and device configured to maximize exposure to gradient and RF fields.
Findings/Discussion
In order to mitigate risks to the patient, design and labeling strategies may be employed. *Labeling strategy:* Testing with a body RF coil showed a 16 - 21.7^{o}C temperature rise at the electrodes with a whole body SAR of 1.5 W/kg when the landmark was positioned over the center of the phantom torso. Testing with a transmit receive head coil only showed a 0.5^{o}C temperature rise at the electrodes with a head SAR of 1.79 W/kg with the MRI landmark centered over the center of the head of the phantom. The labeling strategy is therefore to limit MRI to head scan with a transmit/receive head coil. *Design Strategy:* Design strategies include minimal if any use of ferromagnetic material and incorporation of electromagnetic protection technology such as filtered feedthroughs (FFT) which dissipate RF energy away from the internal circuitry. A circuit configuration with a FFT capacitor will shunt, reflect or absorb EMI before it can enter the device housing and re-radiate into internal circuitry. The presence of the FFTs mitigates the EMI risk and results in fully functional devices following MRI exposure.
Summary/Conclusion
Currently, only the Medtronic line of products has regulatory approval (US FDA and CE) for an MRI conditionally safe scanning for head MRI. Patients can safely undergo head MRI scans with close adherence to the MRI requirements detailed in the device labeling.

18F-Labeled Sodium Fluoride PET and Central Nervous System Imaging: Incidental Findings and the Potential of Hybrid PET/MR

Kessler, B. A.·Lee, Y.
University of North Carolina School of Medicine
Chapel Hill, NC.

Purpose
18F-labeled sodium fluoride (18F-NaF) is a bone-seeking agent primarily used in the evaluation of osseous metastatic disease. With the increasing availability of clinical PET/CT, imaging of bone disease with 18F-NaF may

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

soon be a standard supplement or alternative to traditional bone scintography. Characterization of CNS pathology by 18F-NaF PET/CT has been largely unexplored. The increased clinical use of 18F-NaF PET/CT warrants an understanding of incidental CNS findings and the potential of 18F-NaF PET/CT as an adjunct to standard imaging of brain and spine pathology.
Approach/Methods
Retrospective overview of illustrative cases from UNC.
Findings/Discussion
Recent interest in 18F-NaF PET/CT for the evaluation of malignant and benign bone disease demonstrates its significant advantages over traditional bone scintography. As the availability of clinical PET/CT imaging increases, 18F-NaF PET/CT is likely to play a greater role in the diagnosis and management of bone disease. As such, the characterization of CNS pathology via 18F-NaF, both incidentally and as an adjunct to standard brain and spine imaging, is of great interest. Using illustrative cases, this educational exhibit reviews MRI of CNS pathology with concurrent 18F-NaF PET/CT imaging. Scans are fused when feasible to present the advantages and limitations of the modalities as separate and combined scans. Specific pathologies discussed include brain and skull metastases, spine metastases, cerebral artery infarcts, meningioma and crossed cerebellar diaschisis. Concurrent 18F-fluorodeoxyglucose (18F-FDG) PET/CT imaging is used for comparison in addition to a brief review of uptake mechanisms for both 18F-NaF and 18F-FDG. With the advent of hybrid PET/MR imaging, a discussion of the current state of clinical PET/MR is presented with preliminary hybrid PET/MR imaging. Finally a brief overview of the potential of clinical hybrid PET/MR using both 18F-NaF and 18F-FDG in the diagnosis and management of CNS pathology is presented.
Summary/Conclusion
As the use of 18F-NaF PET/CT for imaging of bone disease increases, its incidental characterization of CNS pathology is of great interest. 18F-NaF may provide additional information in certain CNS pathology, and has a potential role in hybrid PET/MR imaging of the brain and spine.

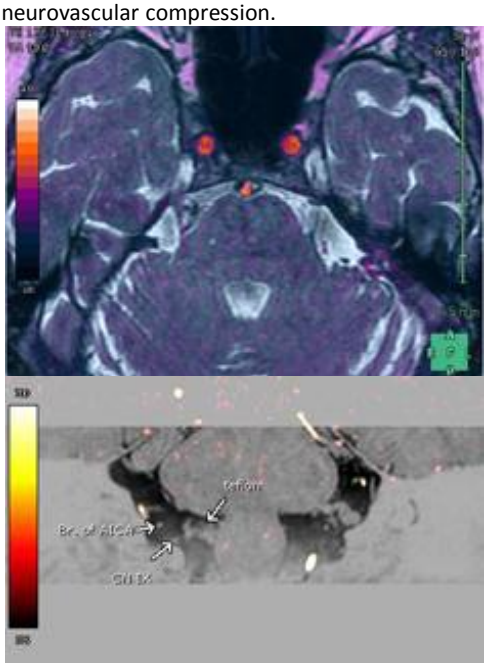
EdE-28

Utility of Coregistered 3D MR Cisternography and 3D MR Angiography for Imaging Neurovascular Compression Syndromes of the Cranial Nerves

Alderfer, K.·Kim, P. E.·Law, M.·Go, J. L.·Shiroishi, M. S.·Boyko, O.·Lerner, A.
University of Southern California
Los Angeles, CA.

Purpose
• Review conventional MR imaging techniques for diagnosis and evaluation of neurovascular compression syndromes of the cranial nerves. • Describe advanced imaging techniques including coregistered 3D MR cisternography and 3D MRA for evaluation of these disorders. • Discuss utility and advantages of this technique in diagnosis and postoperative evaluation of neurovascular compression syndromes.
Approach/Methods
Review the characteristic MRI features of neurovascular compression syndromes of the cranial nerves. Review MR cisternography and MRA for diagnosis and evaluation of these disorders. Discuss challenges and limitations of conventional MR imaging. Demonstrate the utility and methods of coregistered 3D MR cisternography and 3D MRA for evaluation of these disorders. Discuss the role of this technique in diagnosis and postoperative evaluation of trigeminal neuralgia, glossopharyngeal neuralgia, and other neurovascular compression syndromes.
Findings/Discussion
Neurovascular compression of the cranial nerves can be visualized using conventional techniques such as MR cisternography and MRA. However, coregistration of 3D MR cisternography and 3D MRA allows for more precise evaluation of the complex relationship between cranial nerves, vascular structures and postsurgical changes such as Teflon sponge placement. This technique is particularly useful in differentiating arterial and venous structures in neurovascular compression.



Summary/Conclusion
Imaging of the neurovascular compression disorders of the cranial nerves is challenging due to the complex relationship between cranial nerves and surrounding vascular structures. We describe our experience using coregistered 3D MR cisternography and 3D MRA, which allows more precise preoperative evaluation of these disorders and may assist in surgical planning. This technique is particularly useful in postsurgical setting and in evaluation of venous neurovascular compression.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

EdE-29

Strategies for Reduction of Radiation Dose and Contrast Media Volume in Neuro CT without Compromising the Image Quality

Shankar, J.·Pretty, L.
Queen Elizabeth II Health Science Centre
Halifax, NS, CANADA.

Purpose
Radiation from medical imaging has been a very important issue due to its long-term cumulative effects. There has been an impetus in reduction of radiation dose as much as possible without compromising the diagnostic quality of images. Similarly contrast nephropathy is a potential hazard from the computed tomography (CT) contrast media, which could potentially be dose related. We should also try to reduce the contrast media volume as much as practically possible without compromising the diagnostic quality of the images. The purpose of this study is to describe the various techniques/methods we used to reduce the radiation and contrast dose in different CT techniques used for neuroradiology.
Approach/Methods
On Siemens Definition Flash 128 slice dual energy scanner, we applied different techniques starting in June 2012 to reduce both radiation and contrast dose for neuroimaging. For plain head CT and CT angiograms (CTA), we utilized SAFIRE (Sinogram Applied Iterative Reconstruction), mA dose modulation and Care kV (modulation) to reduce the radiation dose. For postcontrast CT head, we used dual energy technique to potentially reduce the radiation dose. For CT perfusion (CTP), we used lower mA of 100 instead of 200 mAs to reduce the radiation dose despite prolonging the total time of imaging to include the permeability data acquisition. We reduced the dose of contrast media for all neuro CT angiograms.
Findings/Discussion
Application of all changes for reduction of radiation and contrast dose have maintained the image quality. For plain head CT, SAFIRE was applied with a strength of three for all scans - to compensate for reduction in mA, while maintaining image quality. We changed the slice thickness from 5 mm to 3 mm, to visually maintain the image quality. This has resulted in radiation dose reduction of 15%. Postcontrast head CT could be performed with dual energy mode and this can obviate the need of the plain head CT before contrast injection. This can virtually reduce the radiation dose by 50%. Computed angiography angiograms are performed using dual energy (DE). We reduced the quality reference mAs from 360 and 180 to 222 and 111 for kV of 80 and 140 respectively. This has resulted in a radiation dose reduction of 45%. We also reduced the dose of contrast media for CTAs of circle of Willis and carotids from 120 cc to 70 cc without any compromise of image quality. The reduction of mAs in CTP resulted in a radiation dose reduction of 35%. A further reduction of contrast media for CTP from 50 cc to 40 cc was applied. We also reconstruct the CTA from the optimal timing sequence of the CTP, which obviates the need of second acquisition and second bolus of contrast injection for CTA of circle of Willis. This resulted in further reduction of contrast and radiation dose.
Summary/Conclusion
By changing the technical parameters and adopting different strategies, overall radiation dose and contrast dose can be reduced significantly without compromising image quality.

KEYWORDS: Radiation dose reduction

EdE-30

Radiation Dose Reduction in Neuro CT: Clever Adaptation in a Lower Dose World

Tanenbaum, L. N.
Mount Sinai School of Medicine
New York, NY.

Purpose
Dose reduction technologies have gone from novelty to norm in a few short years. Techniques such as iterative reconstruction, x-y-z and selective in plane dose modulation, selectable and automated selection of reduced kV values, and utilization of reduced tube current are now in common use. However, application of the techniques has creating new challenges in day-to-day neuroradiology practice.
Approach/Methods
Based on our multivendor experience and the published literature, we review recent advancement in dose reduction techniques and share some potential solutions to the challenges posed by the application of dose reduction technologies.
Findings/Discussion
The first pass at clinical integration of iterative reconstruction (IR) to neuro CT led to dose reductions of up to 40% with quantitatively equivalent image quality (IQ); however, radiologist acceptance of these IR images has been somewhat variable. Recently we have seen adoption of higher levels of IR and achieved improvements in IQ acceptance, sometimes at dose reductions of 60% or more. Even more aggressive dose reductions are possible in susceptible populations as pediatric and neurosurgical ICU patients. Newer model-based IR techniques have enabled even greater dose reductions than the first wave of IR techniques while providing a beneficial boost in spatial resolution. Additional challenges and opportunities remain. As radiation doses for certain high contrast resolution studies, approach single view X-ray studies (e.g., paranasal sinuses, temporal bones), one must seek creative solutions so that the low contrast detectability of "soft tissue" windows is somewhat preserved. A fuller

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

understanding of the relationship of reduced kV scanning to iodine visualization, low-contrast detectability, noise and net radiation dose is critical to designing protocols that are lower in CTDI. Reductions in contrast media doses are possible/desirable with lower kV techniques and the use of contrast agents with a higher iodine concentration.
Summary/Conclusion
Solutions are available to challenges inherent in associated with dose reduction techniques. These solutions can improve IQ, and may further reduce dose. Opportunities demand a re-thinking of acquisition parameters, contrast media application, and reconstruction techniques.

KEYWORDS: Radiation protection, Iterative reconstruction

EdE-31

Strategies to Safely and Reliably Perform MR Examinations in Patients with Electronic Implanted Devices

Watson, R. E.·Edmonson, H. A.·Patton, A.·Lindell, E. P.
Mayo Clinic
Rochester, MN.

Purpose
An increasing number of patients are receiving electronic implanted devices for treatment of various conditions. Many of these patients will need MR imaging due to ongoing or new medical issues. While some of these devices are MRI unsafe, and an MRI cannot be safely performed, an increasing number of implanted electronic devices are “MRI conditional”, and it is essential that radiologists fully understand the conditions that must be met to scan these patients safely as the potential for severe patient injury or even death is a possibility with some devices if scanning is performed without these conditions being met. The purpose of this presentation is to review the essential factors and required conditions that help ensure safe MRI scanning in these patients.
Approach/Methods
Up to date specific conditions permitting safe scanning of several electronic implanted devices, including several neurostimulators, cardiology-related implants including cardiac pacemakers and insertable loop recorders, and intrathecal infusion pumps are described, including prescanning device evaluation and preparation, specified MRI field strength, specific absorption rate (SAR) limitations, required coil types, value of MRI physicist participation, and postscanning evaluation.
Findings/Discussion
Specific conditions that help facilitate safe scanning of patients with deep brain stimulators, vagal nerve stimulators, spinal cord stimulators, sacral nerve stimulators, auditory brainstem implants, cochlear implants, cardiac pacemakers and defibrillators, insertable loop recorders, and intrathecal infusion pumps are reviewed. All prescanning evaluations must focus first on obtaining specific information about the implanted device, including make and model, and in the case of some sacral nerve stimulators, even the serial number of the device is important to determine whether safe scanning can occur. Prior to entering the MRI environment, several devices must be assessed, programmed, or turned off. Devices with leads must be assessed for lead integrity. With several devices, scanning must be performed with transmit/receive coils in which RF energy is contained to the scanned body part. These coils do not permit parallel or accelerated imaging. With some devices, limiting RF energy deposition (SAR limits) is a condition, and close collaboration with an MRI physicist can be beneficial to tailor the exam to create the best possible images within these constraints. Due to susceptibility artifacts from the devices, sequences need to be selected that will minimize image degradation in areas of interest. In the case of cochlear implants, due to concerns of potential infection, some work is proceeding in which the device magnet is left in place while scanning proceeds with the head tightly wrapped.
Summary/Conclusion
An increasing number of implanted electronic devices are being classified as MRI conditional, and with proper precautions, patients can benefit from MRI. However, it is imperative that radiologists fully understand all the factors that must be addressed to permit safe scanning in these patients.

Review of Stable Xenon Portable CT Perfusion Imaging of the Brain: Technical Factors, Safety and Clinical Applications

Mojtahed, A.·Hart, B. L.·Hayek, R. A.
University of New Mexico
Albuquerque, NM.

Purpose
To enhance the knowledge of practicing radiologists regarding: the principles behind, the safety and technical factors regarding, and the applications of stable xenon CT brain perfusion imaging in the clinical setting.
Approach/Methods
Selected cases of xenon perfusion imaging performed at an academic tertiary referral hospital over a six-year period were chosen to illustrate a variety of acute and nonacute neurovascular disease states.
Findings/Discussion
Discussion of technical factors of acquisition, discussion of safety concerns, and discussion of normal brain perfusion parameters including discussion of the autoregulatory processes encountered to maintain brain perfusion are illustrated in a case-discussion format. Cases presented include examples of normal brain perfusion, perfusion in moyamoya disease and balloon occlusion perfusion testing. Special emphasis is placed on portable xenon

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

perfusion imaging in the ICU setting as a guide for medical management in treatment of vasospasm.
Summary/Conclusion
Stable xenon CT brain perfusion imaging is a safe and reliable method for acquiring quantitative cerebral perfusion information. Brain perfusion changes in many neurovascular disease states are clearly demonstrated using the stable Xenon CT perfusion technique, and portable stable xenon CT perfusion data can be used to alter patient management in the Neurointensive Care Unit setting. Through this exhibit we hope to enhance our readers' knowledge regarding stable xenon CT perfusion imaging.

EdE-33

Secondary Degeneration after Stroke: MR Imaging Features with Emphasis on Diffusion-Weighted Imaging Findings

Kinoshita, T.·Kinoshita, F.·Umetsu, A.·Miyata, H.
Research Institute for Brain and Blood Vessels-Akita
Akita, JAPAN.

Purpose
The purpose of this exhibit is to demonstrate MR imaging features of secondary degeneration after stroke. Slower water diffusion in the degeneration may be implicated in their hyperintensity at diffusion-weighted imaging (DWI). This exhibit will review DWI hyperintense lesions representing secondary degeneration.
Approach/Methods
A retrospective review of MR examinations of patients with subacute cerebral infarction or hemorrhage was undertaken. Findings of DWI and T2-weighted imaging were reviewed. Wallerian degeneration is anterograde axonal degeneration after proximal neuronal injury. Wallerian degeneration after middle cerebral artery (MCA) infarction involves the descending corticospinal tract, definable on MR imaging at the internal capsule, cerebral peduncle, basis pontis, and medullary pyramis. Pontine infarction can cause Wallerian degeneration of the pyramidal tract and pontocerebellar tract. Secondary degeneration of the substantia nigra in the midbrain is caused after striatal injury. Thalamic degeneration occurs after MCA infarction. Illustrative case material interpreted as secondary degeneration is presented with reference to DWI findings. One autopsy case of old pontine infarction with Wallerian degeneration was included in this exhibit.
Findings/Discussion
Wallerian degeneration after MCA infarction affects the ipsilateral descending cortiospinal tract. At one-two weeks, hyperintensity along the corticospinal tract can be seen at DWI. A coronal DWI taken along a straight line between the front edge and the deepest point of the interpeduncular cistern can clearly demonstrate the early change of Wallerian degeneration of the segment of the corticospinal tract between the internal capsule and the medulla oblongata. At one-two months, a well-defined band of low signal-intensity appears on T2-weighted images in the topographic distribution of the corticospinal tract. After 10-14 weeks, the signal becomes high signal. Over several years, accompanying corticospinal tract atrophy is seen. Wallerian degeneration after pontine infarction affects the ipsilateral pyramis of the medulla oblongata. Bilateral middle cerebellar peduncle lesions showing T2 high signal after pontine infarction involving the pontine nuclei are interpreted as Wallerian degeneration of the pontocerebellar tract. Coronal T2-weighted imaging can clearly display curvilinear high signal lesions in the bilateral pontocerebellar fibers adjacent to the pontine infarct. Occasionally, the corresponding middle cerebellar peduncle lesions show mild hyperintensity at DWI. In an autopsy case of pontine infarction, T2 high signal lesions in the pontocerebellar tracts corresponded to Wallerian degeneration histologically showing loss of myelinated fibers and fibrillary gliosis. In the subacute period of striatal stroke, MR imaging reveals secondary degeneration of the ipsilateral subasutantia nigra with abnormal T2 signal and restricted diffusion. In patients with MCA infarction in the late subacute period, DWI and T2-weighted imaging disclose involvement of the ipsilateral dorsomedial thalamus.
Summary/Conclusion
Awareness of DWI signal abnormalities in secondary neuronal degeneration due to the original infarct is clinically important. This should not be mistaken for other pathologic conditions, such as a new infarction.

KEYWORDS: Diffusion MR imaging, Wallerian degeneration, cerebral infarction

EdE-34

Cerebral Fat Embolism: Imaging Features Observed over Time in One Medical Center

Shreter, R.·Shreiber, R.·Barlavie, Y.·Goldsher, D.
Rambam Medical Center
Haifa, ISRAEL.

Purpose
This study reports a retrospective examination of the imaging findings of cerebral fat embolism (CFE) in the acute phase, and changes observed over time in follow-up studies.
Approach/Methods
A search of the database of Rambam Health Care Campus revealed seven patients who were diagnosed with CFE between the years 2006 and 2012. The study was approved by the institutional ethics committee, with exemption from informed consent. Of the seven patients, one was female and the rest were male, ages ranging between 20 - 64 years (average 40 years). Six were trauma

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

patients with fractures of long bones and the seventh had sickle cell anemia. All patients initially underwent a brain CT indicated by neurologic or mental deterioration. One of them died shortly after the CT, and six went on to have an MRI examination one to five days following admission. Four of the six underwent a second MRI seven to 35 days after the first. Three patients had long-term follow-up MRIs performed five to 35 months later. Demographic and clinical data for each patient was collected from their charts. Imaging features from all the CT and MRI studies for each patient were reviewed.

Findings/Discussion

CT studies were interpreted as normal in three patients and abnormal in the other four. Of the abnormal CT studies, two had diffuse low attenuation regions in the white matter and the third had low attenuation lacunae demonstrated in the basal ganglia. One of the three died within several days. The second and third patients remained in a deep coma. MR imaging findings in the six surviving patients displayed two different patterns: 1. Miliary distribution pattern (previously described as "starfield pattern") of multiple punctuate lesions of high intensity on T2-weighted imaging (WI) and FLAIR, and restricted diffusion. This pattern was observed in four patients. 2. Scattered high-intensity lesions on T2WI without clear restricted diffusion, which appeared in two of the patients. In the follow-up exams, the hyperintense T2WI lesions shown in the acute phase tended to coalesce and then fade away. This feature was observed in five patients. Cerebral progressive atrophy developed in five of six patients. The one patient who initially had only a very few hyperintense T2WI lesions and no foci of restricted diffusion did not develop cerebral atrophy.

Summary/Conclusion

Cerebral fat embolism may present with two distinct imaging patterns on MRI (T2WI and DWI). The hyperintense T2WI lesions shown in the acute phase tend to coalesce and fade away over time. Cerebral atrophy may appear, and its severity directly correlates with the initial presentation. Low attenuation of the white matter on CT may predict a worse prognosis. Recognizing the typical imaging patterns on initial MRI is important to determine appropriate treatment to prevent further immediate and long-term neurologic deterioration.

Complications of Intraventricular Shunts: A Review of Imaging and Pathology

Mabry, L. M.·Gaddamanugu, S.·Harris, A. L.·Vattoth, S.·Cure, J. K.·Sullivan, J. C.
University of Alabama Birmingham
Birmingham, AL.

Purpose

Intraventricular shunting is a common procedure performed to relieve hydrocephalus. In adults, the most common cause of hydrocephalus is normal pressure hydrocephalus or from prior meningitis. In children the most common cause is congenital aqueduct stenosis or from a brainstem tumor. Complications from intraventricular shunts are rare, but clinically significant.

Approach/Methods

Complications from intraventricular shunting may not present clinically. Both computerized tomography and magnetic resonance imaging are useful imaging techniques to assess complications. This exhibit will review the complications of intraventricular shunting by illustrating complications on cross-sectional imaging.

Findings/Discussion

Complications from intraventricular shunting are diverse. Common complications include shunt malposition which may lead to progressive hydrocephalus. Other common complications include intracranial hemorrhage, either in the cerebral parenchyma or within the ventricles. Less common complications include overshunting resulting in intracranial hypotension, ependymitis, intracranial foreign body, trapped ventricle or formation of intracranial inclusion cyst. Most of these complications are better assessed by magnetic resonance imaging. However CT is well utilized to demonstrate serial changes in ventricle size, which can identify under or overshunting.

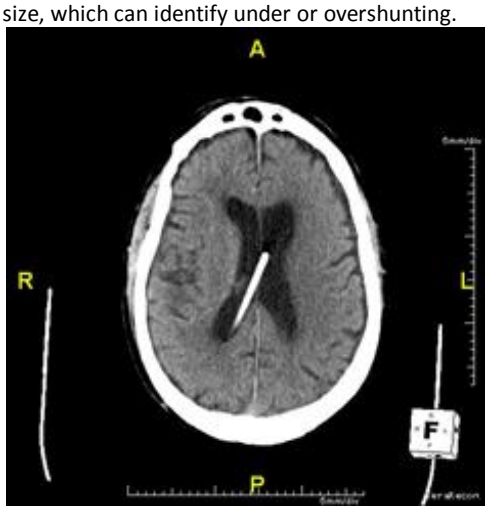

Figure 1: Overshunting of the ventricles leading to prominent extraaxial spaces.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

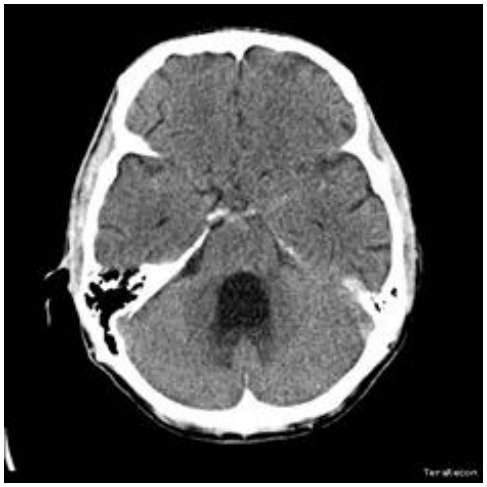

Figure 2 : Trapped 4th ventricle after lateral ventricle decompression. Patient had a history of ependymitis which caused fibrosis at the acqueduct.

Summary/Conclusion

Intracranial complications from intraventricular shunting are rare. However recognition of these complications is essential for patient management. Our exhibit will review these complications with various illustrations.

Neurovascular Dissections: Spectrum of CT and MR Imaging Findings

Mehdi, E.·Aralasmak, A.·Sharifov, R.·Asil, T.·Alkan, A.
Bezm-i Alem University
Istanbul, TURKEY.

Purpose

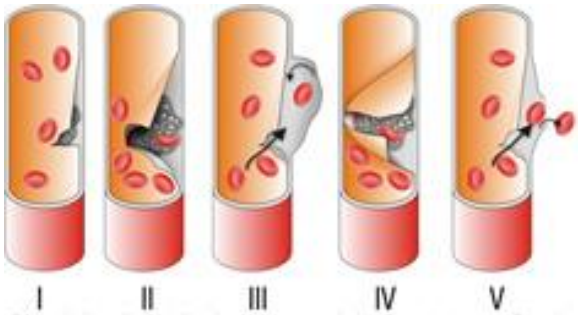
Craniocervical dissection is a crucial emergency state causing 20% of strokes in younger patients under the age of 45, usually resulting from hemorrhage into the vessel wall. The purpose of this educational exhibit is describing the imaging findings of craniocervical dissections in order to familiarize the radiologist with the range of entities.

Approach/Methods

Routinely performed computed tomography (CT) and magnetic resonance imaging (MRI) angiography of patients with craniocervical dissection findings were reviewed prospectively.

Findings/Discussion

Cases have been classified and illustrated into five types of Denver's criteria. The location of dissection, vessel lumen changes and possible hematomas were discussed and showed tricks to distinguish findings from similar pattern seen in other diseases.



Schematic views of arterial dissection anatomy categorised by five grade, known as Denver's. I, intimal flap with <25% luminal narrowing. II, intimal flap with >25% luminal narrowing and thrombus. III, pseudoaneurysm. IV, occlusion. V Transection with extravasation.

Summary/Conclusion

MR imaging and CT have emerged as suitable alternatives to digital subtraction angiography (DSA) that can provide complementary information. Classification of imaging findings is the key role of management and treatment of dissections.

KEYWORDS: Dissection, Vessel wall, craniocervical

EdE-37

Current Understanding of Reversible Cerebral Vasoconstriction Syndrome

Trinh, V.·Chao, K.
Kaiser Permanente Los Angeles Medical Center
Los Angeles, CA.

Purpose

Headaches remain a leading symptom in acquiring medical imaging. Review the current literature regarding reversible cerebral vasoconstriction syndrome as a cause of recurrent headaches. Multimodality approach to illustrate the imaging findings of this diagnosis.

Approach/Methods

A relatively new known cause of recurrent thunderclap headaches is reversible cerebral vasoconstriction syndrome. We will review the various clinical presentations, possible associated causes including but not limited to medication- related, metabolic, and a postpartum state. Additionally we will review the key differential diagnoses including the absence of subarachnoid hemorrhage, underlying mass, or confirmed abnormal angiographic findings on two separate studies months apart in the setting of cerebral vasculitis. Finally we will discuss treatment strategies if and when they are needed including the use of calcium channel blockers, glucocorticoids, magnesium sulfate, and observation. The use of angioplasty also has been reported sparingly in the literature.

Findings/Discussion

Radiologists play an important role in the diagnosis of reversible cerebral vasoconstriction syndrome given the abnormal findings on an initial exam should reverse to a normal study on subsequent exam. Excluding the presence

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

of subarachnoid hemorrhage or other possible intracranial diagnoses is important in the treatment of the patient's recurrent headache.
Summary/Conclusion
Understanding the diagnosis of reversible cerebral vascoconstriction syndrome will help the appropriate interepretation of CT/MR angiographic studies in the patient with recurrent headaches.

KEYWORDS: Headaches, Vasospasm, vasculitis

Many Faces of Cavernous Angiomas of the Central Nervous System

Marquez, J. C.[1,2]·Calle, S.[1]·Rodriguez, F.[1]·Castillo, M.[3]
[1]Pontificia Universidad Javeriana - Hospital Universitario San Ignacio, Bogota, COLOMBIA, [2]Resonancia Magnética del Country, Bogotá, COLOMBIA, [3]University of North Carolina at Chapel Hill, Chapel Hill, NC.

Purpose
Our purpose is to highlight the demographics, clinical presentation, and imaging features of cavernous angiomas (CA) of the CNS with special emphasis on their varying locations and appearances, including lesions found in the supratentorial region, brainstem, cerebellum, ventricles, and/or spine, in addition to those associated with radiotherapy or familial cavernous angiomatosis and with those that present with complications such as hemorrhage or edema, with the intention of providing key imaging findings that may aid the radiologist in detecting this potentially curable clinical entity.
Approach/Methods
We collected cases of CAs from the databases at our institutions. CT, MR and/or angiographic studies were evaluated and lesion size, location, imaging characteristics, multiplicity, and associated findings were recorded. The scientific literature pertinent to the subject was reviewed in order to illustrate a practical approach to identifying these malformations based on our personal experience in conjunction with currently available information.
Findings/Discussion
Cerebral CAs also known as cavernous hemangiomas, are a relatively common benign vascular neoplasm composed of sinusoid-type blood vessels that assemble into a compact mass that histologically shows little or no intervening neural parenchyma. They can occur anywhere in the spine or brain and account for approximately 8-15% of the vascular malformations in these locations. Cavernous angiomas may present as solitary or multiple masses with certain “alarming” characteristics that, to the inexperienced eye, may mimic more aggressive or malignant entities. The importance of recognizing these lesions lies in the potential for treatment, curability and a favorable prognosis in these patients. Understanding the typical features of CAs depending on their anatomical location within the brain is essential in order to provide a correct diagnosis.
Summary/Conclusion
Cavernous angiomas in the brain may display overlapping features with other CNS masses. Associated complications seen occasionally in these lesions, such as hemorrhage and surrounding edema, may further divert the radiologist from the accurate diagnosis. For this reason, detailed knowledge of the imaging characteristics encountered in patients with CAs is essential in order for the radiologist to not be misled by apparently suspicious findings.

On the Shoulders of Giants: “Elemental Brain Volumes” Derived from Modifications of Prior Parcellation Strategies Help to Explain Glial Tumor Spread

Hamilton, J. D.[1]·Hayman, L. A.[2]·Kumar, V.[1]·Schellingerhout, D.[1]·Shah, K.[1]·Chi, L.[1]·Hunter, J.[3]·Chavalli, L.[1]·Leeds, N. E.[1]·Prabhu, S.[1]·Kumar, A. J.[1]·Naidich, T. P.[4]
[1]M. D. Anderson Cancer Center, Houston, TX, [2]Anatom-e Information Systems, Houston, TX, [3]Texas Children's Hospital, Houston, TX, [4]The Mount Sinai Hospital, New York, NY.

Purpose
To utilize Brodmann areas and regional myeloarchitecture to define “elemental brain volumes” (EBV) that help to explain the patterns of growth of cerebral gliomas.
Approach/Methods
Glial tumor in the archicortex tends to stay in the archicortex until late in the disease process and we have observed the opposite to also be true. Brodmann used microscopic differences in the cortical lamination to define regional differences in cerebral architecture (cytoarchitecture) now designated Brodmann areas.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Yasargil et al. defined zones of white matter situated deep to the cerebral gyri, conceptualized these zones as peduncles like unto the stalks of cauliflower, and defined specific sectors along the stalks in relation neighboring white matter tracts (sectorial anatomy). Mori et al. and Wedeen et al. utilized DTI-like techniques to demonstrate the locations and orientation of these regional white matter tracts with deep crossing fibers. Taken together, the Brodmann-defined "gyral" segments and segmental sectorial white matter anatomy may be used to define "elemental brain volumes" (EBV). Fractional anisotropy (FA) maps with directional color coding were superimposed on Brodmann defined gyral segments derived from a DTI of a normal subject. Using Yasargil's white matter classification for the "cauliflower-shaped" peduncle, we divided the white matter into superficial (cortical, subcortical, and subgyral sectors), neocortical deep (gyral and lobar sectors), and archicortex (capsular sector and deeper).
Findings/Discussion
The FA maps demonstrate that the superficial and archicortical white matter tend to run in parallel to each other, in contradistinction to the meshwork of crossing fibers in the deep white matter of the corona radiata and sagittal striatum. These crossing fibers may act as a barrier explaining the observations in the glioma behavior better than prior methods, and can provide the rationale for parceling the superficial white matter into Brodmann-defined segmental myeloarchitecture, the EBV. Almost all of the frontoparietal EBVs conform to a single superficial white matter "stalk" with the segmental myeloarchitecture running in parallel, even for areas that split a gyrus in half, such as Brodmann area 4 and 6 in the pre-central ("motor") gyrus. Additionally, subcortical "U-fibers" tended to connect gyri within Brodmann areas and not between them. Some areas such as the basal temporal and occipital lobes demonstrated an intermediate, transitional morphology with multiple short "stalks" of superficial fibers. (Please note that specific analysis of the survival data and the utility of EBVs for predicting patient survival are submitted to this meeting as a separate communication.)
Summary/Conclusion
Parcellation of the brain into gyral segments by Brodmann areas and defining the corresponding segmental sectorial myeloarchitecture establishes a set of "elemental brain volumes" that correlates to DTI and may help to define the patterns of local growth and spread of cerebral gliomas. This exhibit illustrates the patterns of these elemental brain volumes and their utility in clinical diagnosis.

EdE-40

Hippocampus: A Pictorial Overview of the Embryonic Development, Normal Anatomy, Function and Pathology

Carranza, V. L.·Gupta, S.·Tuna, I.·Bhalla, M.·Mannem, R.·Leighton, M. P.·Ulmer, J. L.·Klein, A. P.
Medical College of Wisconsin Affiliated Hospitals
Milwaukee, WI.

Purpose
To provide a pictorial overview of the embryonic development, normal anatomy and function of the hippocampus, specifically its role in memory, and to present magnetic resonance imaging (MRI) of the most common hippocampal pathology.
Approach/Methods
A literature review was conducted to provide the information for this educational exhibit. Normal anatomy is presented in the form of illustrations, MR imaging and gross pathologic specimens. Magnetic resonance imaging of disease processes that affect the hippocampus is demonstrated.
Findings/Discussion
The hippocampus is a fascinating structure of the limbic system, with intricate anatomy and several vital functions, including consolidation of new memories, emotional responses, navigation and spatial orientation. With the help of illustrations, MRI and gross pathologic specimens, we have provided a closer look at the anatomy, which will help when looking for hippocampal abnormalities. A thorough understanding of the embryology, normal anatomy and function of the hippocampus is beneficial in making the imaging diagnosis of many disease processes that affect the hippocampus. The hippocampus is a vulnerable area affected or thought to be affected in many disease processes including Alzheimer disease, epilepsy, stress related illnesses, schizophrenia and amnesia; all of which have deficiencies in one or many of the functions of the hippocampus we have mentioned. Abnormalities in the hippocampus can be seen on imaging with these disease processes and others, and the key imaging features are important to know.
Summary/Conclusion
It is the hope that this educational exhibit will broaden the reader's understanding of the complexity of the hippocampus.

KEYWORDS: Hippocampus, Memory

Angiographic Anatomy of the External Carotid Artery Branches and their Anastamoses with the Ophthalmic Artery

Shaikh, H.·Patel, N.·Pukenas, B.·Bagley, L.·Hurst, R.·Smith, M.
Hospital of the University of Pennsylvania
Philadelphia, PA.

Purpose
The aim of this exhibit is to illustrate the angiographic anatomy of the external carotid artery branches and their vascular anastamoses with the ophthalmic artery.
Approach/Methods
Evaluate common and external carotid artery angiograms performed at our institution in the last two years. Angiographic images and illustrations will be used to delineate the anatomy of the external carotid artery branches and some of their important anastamoses with the ophthalmic artery.
Findings/Discussion
The external carotid artery branches supply the face, scalp, dura and calvarium, but also have many important anastamoses with the internal carotid and vertebral arteries. These anastamoses help mantain blood flow in locations that are supplied by vessels that are diseased or congenital variants. Anastomoses to the ophthalmic artery may arise from the facial artery, superficial temporal artery, and internal maxillary artery. A diligent search for these anastamoses must be undertaken before performing embolization procedures involving these external carotid artery branches, as these branches are also potential conduits of embolization material to the ophthalmic artery, potentially causing blindness, stroke, and even death. Understanding the external carotid vascular anatomy, as well as paying close attention to the ophthalmic artery anastomoses will help guide neurointerventionalists during evaluation and treatment of diseases.
Summary/Conclusion
The external carotid artery angiographic anatomy is important to understand in order to diagnose diseases, understand vascular variants, and treat vascular abnormalities. Three of the external carotid artery branches often anastomose with the ophthalmic artery. Recognizing the angiographic appearance of these anastamoses is important for the neurointerventionalist in order to minimize risk of devastating complications including stroke, blindness, or death.

KEYWORDS: External carotid artery, Anastomosis

Pitfalls/Perils of Cross-Sectional Imaging: 40 Years of Mimics

Park, J.·Kagetsu, N.
St. Luke's-Roosevelt Hospital Center
New York City, NY.

Purpose
Due to increased utilization of cross-sectional imaging (MR, CT), numerous pitfalls have emerged that may mimic pathologies and result in misdiagnosis. The purpose of this study is to review common pitfalls that have been historically encountered, examine published literature on correlative cases, and evaluate ways to avoid errors in diagnosis.
Approach/Methods
We examined pitfalls commonly encountered during the advent of computed tomography in the 1970s and early 1980s and then during the era of magnetic resonance imaging (MRI) in the late 1980s to the present. The literature was reviewed for further information regarding the avoidance of misdiagnosis.
Findings/Discussion
With the advent of CT and MRI, normal anatomical variants were initially confusing to radiologists who had never seen these structures in three-dimensional imaging. Pitfalls that we evaluated and reviewed include: masslike appearance of the flocculus and nodulus on early CT, turbulent flow artifacts in thoracic spine MRI, petrous apex fat leading to misinterpretation of the contralateral normal petrous apex marrow on MRI, volume averaging leading to overdiagnosis of intramedullary and central

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

pontine lesions on MRI, and pneumatization of the clinoid process mimicking an aneurysm on MRI.
Summary/Conclusion
Although the emergence of cross-sectional modalities such as computed tomography and magnetic resonance imaging provided increased diagnostic power, there initially was confusion with certain normal variants. We present several pitfalls that neuroradiologists have historically encountered and should be aware of when interpreting cross-sectional imaging. Understanding these commonly encountered variants and artifacts can improve the quality of diagnosis and decrease diagnostic misinterpretation.

KEYWORDS: Anatomy, Normal variant

Predicting the Spread of Glial Tumors: Lessons from the Auditory Cortex

Hunter, J. V.[1]·Hamilton, J.[2]·O'Donoghue, D.[3]·Pagani, J.[3]·Hayman, L.[4]·Kumar, V.[2]·Kumar, A. J.[2]·Naidich, T. P.[5]
[1]Texas Children's Hospital, Houston, TX, [2]M. D. Anderson, Houston, TX, [3]University of Oklahoma Health Science Center, Oklahoma City, OK, [4]Sunset Clinic, Houston, TX, [5]Mount Sinai Hospital, New York, NY.

Purpose
To describe the behavior of gliomas of the transverse temporal gyrus of Heschl.
Approach/Methods
Six cases of glioma involving the transverse gyrus were collected. The fiber connections of this gyrus with the surrounding superior temporal gyrus and insula were overlaid to indicate the relationship of the glioma to the long association fibers (arcuate), projection tract (corticothalamic to medial geniculate) and anterior commissural fibers. Four cerebral hemispheres were dissected to investigate the superficial white matter.
Findings/Discussion
Glial tumors of the auditory cortex have a predictable appearance. They do not spread along the known long association, projection or commissural fiber tracts. They do not expand or invade the adjacent superior temporal gyrus. Instead, gliomas beginning in the transverse gyrus enlarge the gyrus and then cross the inferior limiting sulcus of the insula to invade the posterior insular white matter. Gliomas beginning in the posterior insula spread along the same path into the auditory cortex. Anatomical dissection demonstrated this superficial white matter pathway between the insula and the transverse temporal gyrus.
Summary/Conclusion
Anatomical dissections and the natural behavior of gliomas identify superficial association fibers that interconnect the posterior insula with the transverse temporal gyrus of Heschl. These fibers define a discrete cortical segment which defines the limits of early tumor growth.

KEYWORDS: Neoplasm, Anatomical results, Heschl gyrus

EdE-45

Intracranial Hypotension: What Every Radiologist Needs to Know

Sanghvi, T. S.·Young, S. J.·Patel, S. T.·Bidari, S.·Bennett, J.·Quisling, R.
University of Florida
Gainesville, FL.

Purpose
Intracranial hypotension, an underdiagnosed treatable etiology of neurologic symptoms, remains to be well defined in the radiologic literature. The purpose of this educational exhibit it to describe the currently reported imaging findings of intracranial hypotension and define, in patients with those findings, relationships across the incisura and foramen magnum. The features of intracranial hypotension will be understood better and recognized by establishing the normal relationships between certain structures relative to the orienting planes of reference (i.e., the planes of the tuberculum sellae, incisura, and foramen magnum), defining the specific elements constituting central incisural, cervicomedullary and tonsillar herniation.
Approach/Methods
We describe normal and abnormal MRI measurements of the relationships of specific relevant displaceable structures (i.e., optic chiasm, tuber cinereum, mammilary body, interpeduncular fossa, etc.) with respect to specific planes (i.e., plane of the incisura, long axis of the visual pathway, plane of the diaphragma sella, etc.). Measurements described include distance of the chiasma above the diaphragma sella, angles of the optic pathway to the plane of the tuberculum sellae, distance of iter from the icisural line distance, height of the interpeduncular cistern at the plane of the mammilary body and foramen cecum, relationship of the tuber cinerum to the incisural line, the shape and width of the interpeduncular fossa and the position of the obex/decussation of the pyramids. Other findings noted include venous distension, the thickness of the basilar venous plexus at the mid clivus level and the presence of absence of subdural hematoma(s).
Findings/Discussion
Increasing awareness, and imaging detection, of intracranial hypotension can prevent errors in patient management. For example tonsillar descent in intracranial hypotension would not meet the same criteria for classification as a Chiari I malformation, and therefore posterior fossa decompressive surgery, and resultant cerebellar and brainstem prolapse, could be avoided. If, in this example, the correct diagnosis of intracranial hypotension could be made the patient may alternatively

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

benefit from an epidural blood patch.
Summary/Conclusion
Intracranial hypotension is not an uncommon diagnosis described in the neurosurgical literature. Imaging is often the primary means of diagnosis; however, imaging manifestations may often be subtle and overlooked if proper measurements are not made. We present a few easily identified anatomical relationships to be aware of and systematically evaluate to increase confidence and accuracy in the diagnosis of intracranial hypotension. This systematic approach is critical as intracranial hypotension is a treatable cause of headache and more severe neurologic symptoms such as encephalopathy. Timely diagnosis, and aversion of unnecessary procedures resulting in increased patient morbidity, requires a knowledge of relevant normal and abnormal imaging anatomy.

KEYWORDS: Intracranial hypotension, Diagnostic accuracy

EdE-46

Predicting the Spread of Glial Tumors: Lessons from the Anterior Cingulate Cortex

Hunter, J. V.[1]·Hamilton, J.[2]·Hayman, L.[3]·O'Donoghue, D.[4]·Pagani, J.[5]·Kumar, V.[2]·Kumar, A. J.[2]·Naidich, T. P.[6]
[1]Texas Children's Hospital, Houston, TX, [2]M. D. Anderson, Houston, TX, [3]Sunset Clinic, Houston, TX, [4]Oklahoma Health Science Center, Oklahoma, OK, [5]University of Oklahoma, Oklahoma, OK, [6]Mount Sinai Hospital, New York, NY.

Purpose
To describe the behavior of gliomas of the anterior cingulate cortex.
Approach/Methods
Two cases of glioma in the superior frontal gyrus, five cases of glioma of the posterior cingulate gyrus and seven cases of glioma involving the anterior cingulate gyrus were collected. Four additional cases were identified from the literature. The fiber connections of the cingulate gyrus were overlaid to indicate the location of adjacent projection fibers (corticothalamic to anterior thalamic nucleus and corticostriate to the caudate nucleus). The anterior cingulate has no long association or commissural fibers, according to Krieg. Four cerebral hemispheres were dissected to investigate the superficial white matter.
Findings/Discussion
Glial tumors of the anterior cingulate have a predictable appearance. After substantial enlargement within the cingulate gyrus, they extend along the corticostriate fibers into the corpus callosum and expand into the lateral ventricle. They do not spread along the corticothalamic fiber tracts. Tumors of the superior temporal gyrus and posterior cingulate gyrus do not spread to the anterior cingulate gyrus.
Summary/Conclusion
Anatomical dissections and the natural behavior of gliomas identify patterns of spread from the anterior cingulate gyrus along the corticostriate fibers into the corpus callosum with later bulk growth within the lateral ventricle.

KEYWORDS: Anatomy, Neoplasm, cingulate

EdE-47

Pictorial and Educational Review of "Innominate" Anatomical Structures in Neuroimaging: Can You Name Them All?

Matys, T.[1]·Horsburgh, A.[1]·Ali, T.[1]·Antoun, N.[1]·Massoud, T. F.[2]
[1]Addenbrooke's Hospital, Cambridge, UNITED KINGDOM, [2]University of Cambridge, Cambridge, UNITED KINGDOM.

Purpose
In anatomy the term "innominate" is used to designate many parts of the body that are otherwise unnamed. Etymologically it is derived from the Latin meaning "nameless". In the brain and head and neck the use of the single expression "innominate" to describe several anatomical structures pertinent to neuroradiology causes confusion. To clarify this we review the anatomy of these diverse structures.
Approach/Methods
We analyzed publications on anatomy of the brain and head and neck to determine those structures designated as "innominate". This included aspects of neuroradiographic and neuroimaging anatomy.
Findings/Discussion
The term "innominate" is used to uniquely label the following anatomical structures that are indeed otherwise unnamed: 1) Innominate substance: this lies ventral to the anterior aspect of the lentiform nucleus extending from the lateral preoptico-hypothalamic zone over the optic tract towards the amygdala, and contains the basal nucleus of Meynert, whose cells distribute cholinergic fibers widely in the cerebral cortex, and perhaps undergo selective degeneration in Alzheimer disease; 2) Innominate fossa: a shallow depression between the false vocal cord and the aryepiglottic fold on either side of the larynx; 3) Innominate line: a diagonal line projected in the outer lateral third of the orbit in postero-anterior radiographs of the facial bones or the Caldwell projection of the skull, being a tangential projection of the temporal surface of the greater wing of the sphenoid; and 4) Panoramic innominate line: a vertical line crossing the outer third of the maxillary sinus on an orthopantomogram, corresponding to the intersection of the posterior surfaces of the zygomatic process of the maxilla and the frontal process of the zygoma. More confusingly, "innominate" is used as a synonym for several otherwise named structures. In addition to the relatively well known use of the term for 5) Brachiocephalic artery (first branch of the aortic arch), and 6) Brachiocephalic veins (formed by union of internal jugular and subclavian

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

veins), it also has found its way into the nomenclature of 7) Foramen petrosum (innominate canaliculus or foramen of Arnold): an inconstant foramen in the greater wing of the sphenoid between foramen ovale and foramen spinosum, transmitting the lesser superficial petrosal nerve, and 8) Pterygoalar ligament (innominate ligament of Hyrtl-Calori): found in 1-10% of skulls and made of fibrous strands which, when ossified, form an "innominate" band extending from the undersurface of the greater wing of the sphenoid to the root of the lateral plate of the pterygoid process. This may form an ossified "innominate canal" under which the three deep temporal nerves or the motor part of the mandibular division of the trigeminal nerve pass.
Summary/Conclusion
Liberal use of the term "innominate" by anatomists to name diverse anatomical structures within the brain and head and neck leads to confusion, especially when some of these structures are otherwise named. In this educational exhibit we review and illustrate these structures pertinent to neuroimaging anatomy.

KEYWORDS: Anatomy

EdE-48

Learning and Remembering the Many Brainstem Syndromes

Zoltani, Z.·Zohrabian, V.
Thomas Jefferson University Hospital
Philadelphia, PA.

Purpose
To review the complex anatomy, organization, and pathology affecting the brainstem in order to more rapidly diagnose such lesions and to understand their complex and often devastating significance.
Approach/Methods
Utilizing a case-based, interactive, and self-study format the normal anatomy of the brainstem nuclei and fiber tracts will be reviewed through anatomical diagrams and corresponding MR images. Lesions affecting the midbrain, pons, and medulla will be reviewed with special attention to commonly encountered brainstem syndromes. The focus of each case will be to understand which cranial nerves are affected and what patient symptomatology may be expected. “The rule of 4” will be discussed as an aid to remembering the location and function of cranial nerve nuclei. Finally, extramedullary brainstem lesions will be briefly touched upon, namely those lesions affecting important passageways for exiting cranial nerves at the cavernous sinus, jugular foramen, and cerebellopontine angle.
Findings/Discussion
There are over 20 eponymously named cranial nerve syndromes, which have been historically well described, and typically result from stroke/ischemia, neoplasm, or demyelinating disease (MS/ADEM) with other less common causes being meningitis, osmotic demyelination syndrome, vascular malformations, and neurodegenerative diseases. We will focus on a few classic cases in addition to highlighting several vascular causes of syndromes caused by occlusion of the basilar and vertebral arteries and their perforating branches. In the midbrain, discussion will focus on the syndromes described by Weber, Benedikt, and Claude which all involve oculomotor nerve dysfunction and variations of weakness and ataxia. In the pons we will consider Millard-Gubler and Foville, which predominately affect the abducens nerve. Lastly, the well-known Wallenberg syndrome and the lesser-known Dejerine syndrome will be taken up and reviewed.
Summary/Conclusion
A thorough understanding of the anatomy, organization, and function of the brainstem can facilitate diagnosis of complex cranial nerve syndromes and allow for more complete recognition of the patient’s symptomatology.

KEYWORDS: Brainstem, Cranial nerve pathology

EdE-49

Real Estate Assessment: Brainstem Infarcts

Klein, A. P.[1]·Baruah, D.[1]·Maheshwari, M.[2]·Ceranske, A.[1]·Gupta, S.[1]·Mark, L. P.[1]·Ulmer, J. L.[1]
[1]Medical College of Wisconsin, Milwaukee, WI, [2]Children's Hospital of Wisconsin, Milwaukee, WI.

Purpose
A case-based educational exhibit created to explore the intricate anatomy of the brainstem with clinical correlation of function/dysfunction in the setting of acute infarction.
Approach/Methods
Nine unique patient cases have been accumulated with high quality MR images showing small focal acute infarcts within the brainstem. Each infarct is localized to a particular anatomical structure within the medulla, pons, or midbrain, and explains the patient’s presenting deficit. Axial diffusion-weighted images (DWI) and axial T2-weighted images from the cases are presented and supplemented with labeled, normal anatomical media including high-resolution cross-sectional photographs of brainstem post-mortem specimens, conventional MR images, and color-coded FA diffusion tensor images (when applicable, for white matter tracts).
Findings/Discussion
Solitary and isolated infarcts of brainstem nuclei and white matter tracts are not uncommonly seen. They often have excellent correlation with clinical dysfunction. Cases of isolated infarcts of the corticospinal tract, spinothalamic tract, oculomotor nucleus, abducens nucleus, motor/sensory nuclei of CN V, spinal nucleus of V, facial nucleus, medial longitudinal fasciculus, and medial lemniscus are presented.
Summary/Conclusion
Familiarity with brainstem anatomy is extremely helpful

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

for a radiologist. Understanding the anatomical and functional relationships can optimize radiologic interpretations on both MRI and CT, in the setting of stroke, and beyond.

KEYWORDS: Brainstem, Infarct

Rare and Unusual Neurovascular Variants Arising from the Internal Carotid Artery

Gajjar, M.[1]·Patel, B. M.[1]·Seth, R.[2]·Hurley, M.[1]·Shaibani, A.[1]·Ansari, S. A.[1]
[1]Northwestern Memorial Hospital, Chicago, IL, [2]Baptist Hospital, Miami, FL.

Purpose
To explore anatomical variations along the internal carotid artery (ICA), and highlight unusual configurations that might be encountered during angiographic imaging. The angiographic appearances, embryologic development, prevalence, and associations of clinically relevant variants with neurovascular pathology will be discussed.
Approach/Methods
We review rare ICA variants, including occipital and ascending pharyngeal-ICA origins; aberrant or aplastic ICAs; persistent proatlantal, stapedial, hypoglossal, and trigeminal arteries; primitive maxillary and mandibular arteries, duplicated posterior communicating arteries with a persistent primitive fetal branch, infraoptic anterior cerebral artery, and dorsal/ventral ophthalmic arteries.
Finding/Discussion
The ICA features a straight cervical course up to the level of the skull base, typically without branch vessels. Ten to 40% of ICAs demonstrate anatomical variation. The occipital artery classically arises from the external carotid artery (ECA), coursing between the occipital bone and C1. Variations in the occipital artery may be due to the presence of abnormal growth factors during embryogenesis and regression of the first and second aortic arches. When the ascending pharyngeal artery originates from the cervical ICA, it represents a dorsal vestige of the third aortic arch. Congenital vascular variants of the middle ear are rare. These patients are at risk of injury during myringotomy or stapes surgery, requiring preoperative recognition. An aberrant ICA is formed by collateral blood flow, which substitutes the cervical and petrous portions of the ICA through branches of the ECA, and includes intratympanic and lateral pharyngeal variants. Persistence of the stapedial artery is rare, and can be associated with an aberrant ICA. The stapedial artery is a normal transient embryonic anastomosis between future ECA branches and ICA, with a prevalence of 0.48%. The persistent trigeminal artery is the most common and most cephalic of the persistent carotid-vertebrobasilar anastomoses (CVBA). Its prevalence is 0.1%-0.6%. Two types have been described and are equally common, lateral parasellar and medial transellar. The persistent hypoglossal artery is the second most common CVBA, with a prevalence of 0.02%-0.10%. It originates from the ICA at the C1-C3 level, traversing the hypoglossal canal, and anastomoses with the basilar artery. Primitive maxillary and mandibular artery are extremely rare and may be seen collateral pathways in the setting of ICA congenital occlusive disease. Duplication of the posterior communicating artery is uncommonly found, with a 2% prevalence of this anomaly found at surgical dissection. Unilateral partial and complete duplications have been described and associated fetal variations have not been entirely characterized. During early embryonic development, two primitive ophthalmic arteries are present, the ventral ophthalmic artery that persists, and the dorsal ophthalmic artery that regresses. In some instances, the opposite occurs, and the dorsal ophthalmic artery from the inferolateral trunk persists. An infraoptic course of the A1 segment of the anterior cerebral artery is a rare anomaly, with only 42 cases reported in the literature.
Summary/Conclusion
Variants of the ICA are rare, typically asymptomatic, and often incidental findings. However, these variants can occasionally influence surgical strategy, temporary occlusion time, embolic risk, and collaterals with potential impact on patient outcomes and postprocedural complications.

From Rootlets to Rami: High-Resolution Imaging of Spinal Nerve Anatomy

Hynecek, R.[1]·Nidecker, A. E.[2]·Wasserman, B. A.[1]·Blitz, A. M.[1]
[1]Johns Hopkins, Baltimore, MD, [2]University of California Davis, Sacramento, CA.

Purpose
Constructive interference in the steady state (CISS) and volume interpolated breath hold examination (VIBE) are high-resolution isotropic gradient-echo MR techniques that are capable of producing exquisite detail of intradural and extradural spinal neuroanatomy. With images capable of submillimeter spatial resolution, it is important for the neuroradiologist to be familiar with the appearance of relevant structures that can be resolved using these techniques in the context of spine imaging.
Approach/Methods
During a 10-month period 39 patients were evaluated with high-resolution spine imaging. The cervical spine MRI protocol included 0.5-0.6 mm coronal isotropic CISS without and with contrast and 0.8 mm coronal isotropic VIBE without and with contrast. Similar parameters were applied to the lumbar and thoracic spine protocols in this series. Acquired data were reformatted into angled

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

oblique views for optimal characterization of the structure being assessed utilizing standard MPR software on the PACS viewer.
Findings/Discussion
Surface anatomy of the spinal cord, dorsal and ventral roots/rootlets, dorsal root ganglia, dural root sleeves, spinal nerves, dorsal and ventral rami, rami communicantes, sympathetic ganglia, denticulate ligaments, and spinal canal structures including the dura, extradural venous system, and neural foramina, were reviewed systematically and are presented as image-based case examples with diagrammatic representations of normal anatomy.
Summary/Conclusion
Isotropic high-resolution imaging provides the capability of visualizing structures not typically seen with standard spine MRI techniques due to the constraints of conventional two-dimensional imaging. An image-based review of anatomical appearances and relationships of these structures is intended to familiarize radiologists with relevant anatomy.

CT and MR Imaging of Sialadenitis

Scher, D. J.·Joshi, A. S.·Taheri, M. R.
George Washington University
Washington, DC.

Purpose
1. To review the causes of sialadenitis. 2 . To review the imaging characteristics of acute and chronic sialadenitis on CT and MRI.
Approach/Methods
1. Patient chart review to identify examples of acute and chronic sialadenitis. 2. Imaging examples of acute and chronic sialadenitis. 3. Literature review of diagnostic imaging of sialadenitis.
Findings/Discussion
Inflammation of the salivary gland is called sialadenitis. Causes of sialadenitis can be broken down into three major categories: obstruction with sialolithiasis, obstruction without sialolithiasis and immunologic or inflammatory. In this educational exhibit, we will focus on cross-sectional image findings of specific examples of each of these categories. Image findings of obstruction with sialadenitis are further characterized using examples of acute, subacute and chronic stages. Obstruction without sialolithiasis is highlighted by idiopathic ductal stenosis of the Stensen's duct. Examples of the immunologic or inflammatory category include infectious adenitis, Sjogren's syndrome, and Kuttner's tumor. A literature review of each of these cases will be provided throughout this exhibit. The educational exhibit will end with several mimickers of sialadenitis, including HIV-related lymphoepithelial lesions and papillary cystadenoma lymphomatosum (Warthin's Tumor).
Summary/Conclusion
Multiple causes of sialadenitis exist, and imaging can play a critical role in honing the differential diagnosis. In this exhibit, the observer should become familiar with the different causes of sialadenitis and with their associated cross-sectional image findings.

KEYWORDS: Sialadenitis

EdE-54

Imaging Findings of Infectious Endophthalmitis

Radhakrishnan, R.[1]·Morales, H.[1]·Cornelius, R.[1]·Cunnane, M. E.[2]·Golnik, K.[1]·Rutty, A.[3]
[1]University of Cincinnati College of Medicine, Cincinnati, OH, [2]Massachusetts Eye and Ear Infirmary, Boston, MA, [3]University of Pittsburgh, Pittsburgh, PA.

Purpose
Endophthalmitis is a rare, but morbid inflammatory condition of the globe with imaging findings less well described. The aim of this exhibit is to illustrate the imaging features of infectious endophthalmitis, with appropriate MRI and CT images. We also will highlight the etio-pathogenesis of infectious endophthalmitis with the aid of easily understandable illustrations.
Approach/Methods
We reviewed our imaging database for illustrative cases of infectious endophthalmitis and also obtained clinical information from the patient's medical chart.
Findings/Discussion
Endophthalmitis is intraocular inflammation predominantly involving the anterior chamber, choroid or vitreous. Infection is often exogenous in etiology secondary to trauma or ocular surgery. Rarely, infection may be endogenous from hematogenous spread of organisms in susceptible individuals. Early disease may

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

have normal imaging findings. There may be mild increase in enhancement of the uveoscleral layer on contrast-enhanced CT or MRI where the rich vascular supply of the choroid serves as a site for initial infection. Hyperdensity of the vitreous on CT or mild increased vitreous signal intensity on FLAIR and T1W MRI, also described as part of early disease, may reflect proteinaceous exudates into the vitreous. More fulminant endophthalmitis can present with ocular abscesses and focal exudates in conjunction with ocular membrane detachment. These focal exudates, which are demonstrated more easily with MRI, can show varying degrees of diffusion restriction and rim enhancement. Concomitantly, there can be edema or inflammation of the episcleral tissues, in the potential sub-Tenon space. Lacrimal gland enlargement often is associated. The end stage of unresolved endophthalmitis is phthisis bulbi, with collapse of the globe and loss of normal contour. Clinically, severity of infection is graded by degree of involvement of the intraocular structures; however, ophthalmoscopy may be suboptimal in these patients. Infectious endophthalmitis is often bacterial in etiology, but viruses, fungi and parasites also can cause ocular inflammation. Noninfectious endophthalmitis from autoimmune or granulomatous conditions such as sarcoid, Beçhet's disease, ANCA associated vasculitis, can have similar imaging appearance.

Summary/Conclusion

Initial diagnosis of endophthalmitis is made clinically and imaging is rarely needed. Imaging is indicated in the more complex, unresponsive patients, where assessment of disease extent and associated complications is needed to plan appropriate management. The radiologist should be aware of the imaging findings, particularly on MRI where the use of DWI can help to differentiate endophthalmitis from noninfectious inflammation of the globe.

EdE-55

CT and MR Imaging Findings in Orbital Lymphoma

Carmody, R. F.·Khan, R.·Nael, K.·Shastri, R.
University of Arizona Medical Center
Tucson, AZ.

Purpose

To present a pictorial display of the many appearances of lymphoma when it involves the orbit. Other conditions that may resemble lymphoma also will be shown. Imaging clues that are helpful in distinguishing lymphoma from other diseases will be discussed.

Approach/Methods

The imaging findings in 23 patients with pathologically proven lymphoma, as well as two additional cases of acute lymphocytic leukemia, were reviewed retrospectively. The CT and MRI scans were examined as to the location of intraorbital disease, MR signal intensity, enhancement patterns, and presence or absence of bone destruction. Patient age and bilaterality of disease also were recorded. Where available, cell type also was noted.

Findings/Discussion

Most cases were non-Hodgkins B-cell lymphomas; two cases of T-cell lymphoma were found, as well as a single case of Hodgkins disease. Most patients were middle aged or elderly, although one case of T-cell lymphoma was in a six-year-old girl, and the other was in a 22-year-old man. Sixteen had bilateral and nine had unilateral involvement. The most common structure affected was the lacrimal gland (15 cases). Twenty-one individuals had extraconal disease, and seven had intraconal findings. The extraocular muscles were infiltrated in eight cases. Two patients had optic nerve sheath thickening. Only one patient had bone destruction. Conjunctival infiltration was seen in two cases. On MRI, lymphomatous tissue was isointense to gray matter on T1- and T2-weighted sequences, with strong enhancement. Restricted diffusion also was present. A characteristic feature of lymphoma was its propensity to "mold" itself to adjacent structures, such as the posterior globe. The entity that is most difficult to distinguish from lymphoma is idiopathic orbital inflammatory disease (pseudotumor), which typically has identical MR signal characteristics and can occur anywhere in the orbit. Metastatic disease also can have similar appearances when it involves the orbit, but is more likely to cause bone destruction. Lacrimal gland sarcoid is sometimes a differential diagnostic consideration, especially in young females. Other lymphoma mimics include primary rhabdomyosarcoma of the orbit, unilateral or asymmetrical Graves disease, and nerve sheath tumors.

Summary/Conclusion

B-cell lymphoma is a not uncommon cause of an orbital mass. Lymphoma often occurs in the lacrimal gland, is isointense on T1- and T2-weightefd imaging, shows restricted diffusion, and demonstrates strong contrast enhancement. A characteristic feature is its tendency to mold itself to the globe. Orbital pseudotumor may have an identical appearance. Lymphoma is unlikely to cause bone destruction.

KEYWORDS: Orbital tumor, Lymphoma

Ooh lala ! Who Has Seen This One Before?: A Medley of Unexpected Foreign Bodies Encountered by Neuroradiologists

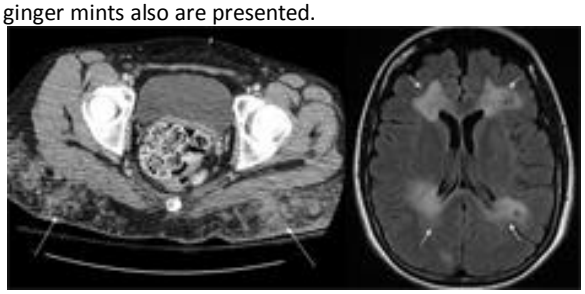
Rehmani, R.·Gandhi, S.·Black, K.
North Shore-Long Island Jewish Health System
Manhasset, NY.

Purpose

To illustrate unusual and often unexpected incidental foreign bodies encountered by neuroradiologists in the head/neck. To increase awareness and highlight clinical relevance of such puzzling cases. A systemic imaging-based classification of such unfamiliar cases into emergent

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

versus nonemergent categories is illustrated. This is supplemented by perplexing imaging appearance of certain exemplary postoperative cases. Multimodality approach is utilized.
Approach/Methods
We retrospectively reviewed unusual cases encountered at a tertiary care academic center in the department of neuroradiology, over a period of five years. These cases then were categorized systematically according to the urgency level requiring immediate management versus nonurgent incidentalomas.
Findings/Discussion
We present an assortment of cases of postfacial augmentation including chin augmentation (mentoplasty), cheek injections and augmentation (malarplasty) and rhinoplasy. We also present a case of multiple buttock augmentation resulting in much unexpected complication of florid multiple sclerosis. On one hand, we present a case of forgotten intracranial Mayfield pin postcraniotomy while on the other hand, we illustrate a case of accidental nail stuck in a patient's head. The normal postoperative imaging features of a case of post-glioblastoma multiforme (GBM) resection Gliadel wafer placement (for chemotherapy) are presented and contrasted from tumor recurrence, a common mimic. Additionally, we present exemplary cases of embedded foreign bodies in the esophagus such as ingested denture, swallowed battery, as well as a case of a very large pork chop stuck in the esophagus. Secondary complications of these often forgotten foreign bodies include walled-off abscesses and distal migration of the ingested material. Computed tomography imaging features of commonly encountered incidental intraoral edibles such as chewing gums and ginger mints also are presented.



Summary/Conclusion
Radiology is at the heart of the modern day practice of medicine. Radiologic assessment of a non-native foreign body is oftentimes difficult in unexperienced hands. The clinical relevance and urgency of such a finding also is emphasized to allow correct and speedy management of patients. It is crucial that radiologists keep themselves abreast with ongoing newer surgical techniques especially in the field of plastic surgery as these patients may present for radiologic imaging at some point in their life for unrelated issues. This exhibit will create awareness and allow better understanding among the radiologists regarding the imaging features of currently prevalent augmentation techniques and their unexpected complications as well as imaging features of a multitude of other unusual foreign bodies in the head and neck.

EdE-57

More than Superficial: A Review of the Major Complications of Malignant Skin Neoplasms of the Head and Neck

Obeng, K. K.·Escott, E. J.·Valentino, J.·Aouad, R. K.·Ponting, J. M.
University of Kentucky
Lexington, KY.

Purpose
Nonmelanoma skin cancers (NMSCs) including squamous cell carcinoma (SCC) and basal cell carcinoma (BCC), and malignant melanoma frequently occur in the head and neck. However, the sometimes quite extensive local invasion and complications associated with these lesions often are not anticipated or well understood by the radiologist. The purpose of this review is to present the imaging findings of the major complications related to the invasion and locoregional metastases of malignant skin neoplasms of the head and neck.
Approach/Methods
Cases were collected by one of the following methods: a retrospective search of the radiology information system (RIS) for those patients who had undergone head and neck imaging (MRI, CT) at the University of Kentucky, Department of Radiology for the evaluation of head and neck skin malignancy, during the dates of January 2011 - July 2012; review of cases presented at the head and neck tumor board; and cases from the authors' personal collections.
Findings/Discussion
Detected complications included direct deep local invasion such as of the orbit, temporal bone or calvarium or parotid gland, especially for SCC. Perineural spread of tumor also was noted. Contrast enhancing nodularity of the surrounding subcutaneous fat and soft tissues about the primary skin lesion thought to reflect locoregional lymphatic invasion and regional lymphadenopathy also could be seen. Invasion of major vessels and other deep structures of the neck also is a feature of the disease.
Summary/Conclusion
Once NMSCs and malignant melanoma of the head and neck are diagnosed, and because of the variety of surgical and nonsurgical options that are available for treatment, careful preoperative assessment by an experienced surgeon, in consultation with a radiologist, pathologist and oncologist may be needed. Imaging frequently is requested to evaluate patients with deep invasion and locoregional metastases of primary skin malignant neoplasms of the head and neck. The noted complications of nonmelanoma skin cancers (NMSCs) and melanoma include deep local invasion such as of the temporal bone

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

or orbit, perineural spread of tumor, metastases and/or invasion of the parotid gland, invasion of major vessels and other deep structures of the neck, and invasion of the skull or cranial vault depending on the type of tumor. The radiologist and clinician needs to be aware of these varied appearances, and therefore may better anticipate the immediate and latent complications following primary diagnosis, thereby facilitating early treatment with fewer complications.

KEYWORDS: Head and neck, Neoplasm, nonmelanoma skin cancers (NMSCs)

EdE-58

Horner's Syndrome: A Practical Approach to Critical Anatomy and Imaging

Parmar, H. A.·Ibrahim, M.·Cornblath, W.·Trobe, J.·Mukherji, S. K.
University of Michigan
Ann Arbor, MI.

Purpose
Horner's syndrome (HS) is a clinical triad of symptoms of ptosis, miosis and anhydrosis first described by Johann Horner in 1869. It results from interruption of oculosympathetic pathway (OSP) and a wide variety of benign and malignant entities can result in HS. While imaging patients with HS it is important for neuroradiologists to understand the anatomy of the OSP, to be aware of different entities within this pathway and choose correct imaging modality to arrive at the right diagnosis.
Approach/Methods
The goal of this exhibit is to give a brief overview of clinical features of HS, review the anatomy of the OSP, and provide the clinical and imaging approach while dealing with these patients. We also will present CT and MRI imaging features of different lesions that involve the OSP.
Findings/Discussion
The clinical approach for HS deals with knowing if it is acute or chronic and if it is isolated or nonisolated. Patients with nonisolated can have symptoms referred to hypothalamus/ brainstem, cervical cord, brachial plexus, carotid artery, neck or the cavernous sinus. On imaging, HS can be classified as preganglionic or postganglionic (with respect to the superior cervical ganglion). Preganglionic HS can be subdivided further into central (interruption of fibers from hypothalamus to spinal cord at C8-T2 level) and peripheral (interruption of fibers from C8- T2 to superior cervical ganglion). Typical lesions involving the preganglionic central pathway include lesions of the hypothalamus, brainstem and cervical cord. Lesions involving the preganglionic peripheral pathway include lesions like apical lung cancer, cervical rib, trauma and certain thyroid cancers. Lastly the lesions involving the postganglioic pathway include lesions of the superior cervical ganglion (trauma, iatrogenic neck dissection), internal carotid artery (dissection, aneurysm, arteritis), skull base and cavernous sinus (tumors, inflammation and cavernous sinus thrombosis).
Summary/Conclusion
Imaging interpretation of patients with HS is difficult due to varied spectrum of different entities producing HS and also due to lack of adequate knowledge of the OSP anatomy. Familiarizing with the critical anatomy of the OSP and the clinical and imaging approaches presented in this exhibit will provide a basic and useful framework for dealing with such patients and arrive at a correct diagnosis.

KEYWORDS: Horner's syndrome, Anatomy, pathology

EdE-60

Know your Notochord: Notochordal Remnants at the Central Skull Base

Conley, L. M.·Zlotchenko, G.·Shatzkes, D.
Lenox Hill Hospital
New York, NY.

Purpose
The notochord is a flexible rod-like structure that defines the axis of the embryo during intrauterine life. In addition to contributing to formation of normal anatomical structures such as the nucleus pulposis, a variety of remnants may persist resulting in a spectrum of lesions ranging from benign variants such as ecchordosis physaliphora to malignant chordomas. Our goal is to provide a radiologic review of notochordal remnants at the central skull base.
Approach/Methods
This educational exhibit will review notochordal embryology and the imaging findings of both normal and variant notochordal remnants at the central skull base. Lesions will be characterized both with regard to their anatomical location along the notochordal tract as well as their clinical significance and presentation. Companion cases emphasizing important differential considerations will be presented.
Findings/Discussion
Developmental variants and neoplasms tend to arise most frequently at the superior and inferior margins of the embryonic notochord (i.e., at the clivus and sacrum). At the central skull base, lesions may be located proximally within the postclival intradural (ecchordosis physaliphora) and extradural (chordoma) spaces, the clivus itself (persistent canalis basalis medianus, fossa navicularis magna) and in the central nasopharynx (Tornwaldt cyst). Characteristic CT and MRI features of these lesions are discussed, with the often difficult distinction between the benign ecchordosis physaliphora and malignant chordoma particularly emphasized. While most represent incidental "don't touch me" findings, those lesions that require further workup, intervention or continued followup are identified.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Summary/Conclusion
Remnants of the notochord at the skull base range from the mundane (Tornwaldt cyst) to the esoteric (ecchordosis physaliphora). Understanding of the relevant embryology will aid in recognition of the characteristic location and imaging features of this diverse group of developmental variants and pathologic entities.

KEYWORDS: Skull base neoplasm, Normal variant, notochord remnants

EdE-61

Tales from the Crypts: Disease Processes of the Tonsillar Fossa

Zlotchenko, G.·Conley, L. M.·Shatzkes, D.
Lenox Hill Hospital
New York, NY.

Purpose
The tonsils have received enhanced attention recently due to the rise in incidence of human papillomavirus (HPV) related oropharyngeal squamous cell carcinoma. Their unique anatomy, with deep crypts and both epithelial and lymphoid elements, allows for a broad range of disease, and some unusual imaging features. Our goal is to provide a comprehensive review of the full spectrum of disease processes affecting the tonsillar fossa.
Approach/Methods
Normal anatomy and pathologic processes of the tonsils and related structures of the oropharynx will be reviewed, with an emphasis on CT, MRI and PET-CT imaging. Patterns of spread, unique imaging features, differential diagnoses, and imaging pitfalls will be addressed.
Findings/Discussion
Pathologic entities affecting the tonsillar fossa can be divided into three major categories: congenital, inflammatory/infectious and neoplastic. Congenital lesions include branchial cleft cysts and vasoformative anomalies such as venous or lymphatic malformations. Inflammatory/infectious lesions can be divided further into acute and chronic subtypes. Chronic processes include hyperplasia, chronic tonsillitis, tonsoliths, and mucous retention cysts. Acute processes represent a spectrum from tonsillitis to tonsillar/peritonsillar abscesses; while these are frequently bacterial or viral in etiology, some less common pathogens such as actinomycosis will be presented. Finally, neoplastic disease, with both common (squamous cell carcinoma, lymphoma) and uncommon (e.g., lymphoepithelioma, sarcoma) entities will be reviewed.
Summary/Conclusion
Though diminutive in size, the tonsillar fossa is disproportionately affected by a wide variety of relatively common disease processes. Knowledge of the details of its unique structural and functional anatomy, as well as characteristic patterns of spread and imaging pitfalls, will aid in formulating accurate and clinically useful differential diagnoses.

KEYWORDS: Oropharynx, Neck lesions, tonsillar fossa

EdE-62

Radiologic Evaluation of Endoscopic Endonasal Skull Base Surgery Candidates

Learned, K. O.·Lee, J. Y. K.·Newman, J. G.·Palmer, J. N.·Bagley, L. J.
University of Pennsylvania
Philadelphia, PA.

Purpose
Endoscopic endonasal approaches (EEA) have expanded beyond the paranasal sinus and sella to become the best surgical corridor to the entire ventral skull base. Using representative cases, we will discuss general principles, key skull base anatomy in relation to surgical access, the diversity of pathology, and the role of preoperative CT and MR imaging.
Approach/Methods
Our institutional and nationally published data on EEAs to skull base surgery are reviewed. The pathologies are categorized by anatomical locations and endoscopic surgical approaches. The preoperative CT and MR imaging are reviewed to illustrate the pertinent radiologic findings for surgical planning. Postoperative MR imaging and clinical followup demonstrate surgical results.
Findings/Discussion
Recent advancements in endoscopic techniques, instrumentation, intraoperative imaging navigation and cranial defect reconstruction enable endoscopic management of benign and malignant processes along the entire ventral skull base, petrous apex and infratemporal fossa as wells as in select cases within the cavernous sinus, suprasellar cistern, and anterior cranial fossa with similar results to those obtained with open craniofacial procedures but with beneficial lower rates of complication. Feasible and safe surgical access and reconstructive options depend upon the paranasal sinus and skull base anatomy of each patient. CT, MR and noninvasive angiographic studies should detail the location of the lesion, assess its relationship to adjacent neurovascular structures and note bony dehiscence, hyperostosis (potentially necessitating drilling) and anatomical variants (Onodi cells, heights of skull base, sphenoid sinus septum relationship with ICA), thus permitting safe surgical access. The endonasal corridor allows excellent access to the midline skull base from behind the frontal sinus to the clivus, permitting optimal lesion exposure and a direct surgical route to the lesion sparing critical neurovascular structures. Therefore, the ventral skull base lesions that are best addressed by the anterior endonasal approaches are located in the true midline without significant lateral extension over the orbital roof and optic nerve or extension posterolateral to

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

the internal carotid artery. Superolateral location in the cavernous sinus, neurovascular encasement, pituitary stalk/hypothalamic involvement and brain invasion increase the difficulty of surgical resection and hence increase its risks. Preoperative radiologic assessment should include anatomical skull base locations based on EEA modules with attention to the above-mentioned critical assessments. Examples of surgical corridors and pathologies are transcribriform (esthesioneuroblastoma, olfactory meningioma), transphenoid (planum-tuberculum meningioma, craniopharyngioma), transclivus (chordoma, foramen magnum meningioma, ventral brain stem lesion) and trans-pterygoid (petrous apex cholesterol granuloma and petroclival chondrosarcoma).
Summary/Conclusion
In many cases, the preoperative radiographic evaluation is not only useful for diagnosis but is also useful for surgical mapping to warrant safe and optimal surgical outcome of EEAs. Both CT and MR imaging evaluation are required for appropriate patient selection and in guiding EEAs.

KEYWORDS: Skull base neoplasm, ENT, endoscopic

EdE-63

Skull Base Reconstruction: Demystifying Postoperative Imaging Evaluation

Learned, K. O.[1]·Maralani, P. J.[1]·Malloy, K. M.[2]·Loevner, L. A.[1]
[1]University of Pennsylvania, Philadelphia, PA, [2]University of Michigan, Ann Arbor, MI.

Purpose
The pathology of the skull base is challenging with complex anatomy and critical neurovascular structures. Collaboration of subspecialists including neuroradiologists, neurosurgeons, and head and neck surgeons is essential for safe and effective surgical resection and reconstruction. Postoperative imaging and clinical followup is even more challenging due to the alteration of normal anatomy. This presentation will review common surgical skull base reconstructions and illustrate a practical approach to postoperative imaging interpretation.
Approach/Methods
We review the commonly encountered skull base defect reconstructions by anatomical location, reconstructive tissues, and surgical techniques. The postoperative CT and MR imaging findings of normal reconstructions, and patterns of neoplastic recurrence will be discussed and illustrated.
Findings/Discussion
An arsenal of nonvascularized and vascularized tissues are employed to reconstruct surgically created skull base defects in order to achieve CSF sealant. For craniofacial resections, large tissue flaps and grafts are primarily utilized. For medium to large paramedian anterior skull base (ASB) defects such as craniofacial resection with bifrontal craniotomy, galeopericranial flap based on supraorbital or supratrochlear arteries is used routinely. CT and MR imaging show folds of tissue in the ASB defect with frontal sinus cranialization. Split thickness calvarial bone grafts rarely are used. Lateral ASB (infratemporal fossa) or lateral temporal bone defects are reconstructed routinely with temporo-parietal fascia with or without the temporalis muscle with preserved vascular pedicle of superficial temporal artery (STA) and/or deep temporal arteries and veins. Fasciocutaneous free tissue transfer has become the main stay for reconstructions with utilization of radial forearm free flaps with radial artery and accompanying vein microanastomosis to STA or facial artery and veins, respectively. These regional flaps and free flaps have characteristic striated muscle bundles, and variable MR signal intensity and enhancement due to multiple factors including scar maturation, resorption of fat, denervation, and in some cases sequel of postoperative adjuvant radiation. These flaps gradually lose tissue bulk due to atrophy. In endonasal endoscopic surgery, multilayer endoscopic reconstruction using pedicled nasoseptal flap is utilized to reconstruct the surgically created skull base defect. In the immediate postoperative period the pedicled flaps have a characteristic C-shaped arc configuration and an enhancing vascular pedicle on MR imaging. Over months the NSF retracts into the denuded skull base defect and sinonasal cavity but maintains its configuration. Neoplastic recurrences typically occur at the interface of the flap recipient bed and reconstructive tissue and appear as new or growing enhancing tissue.
Summary/Conclusion
Understanding the imaging appearance of skull base reconstruction is paramount for accurate postoperative assessment and delineation between normal reconstructive tissue and neoplasm.

KEYWORDS: Skull base neoplasm, Postoperative findings, skull base reconstruction

EdE-64

Hypoglossal Nerve: Anatomy and Causes of Palsy

Meyer, M. A.·Erly, W. K.
University of Arizona
Tucson, AZ.

Purpose
The hypoglossal nerve provides motor innervation to the tongue, and may be affected by pathology at multiple locations along its pathway. Knowledge of its anatomy and careful examination of the tongue are important in the diagnosis of lesions and determination of appropriate testing. Normal anatomy, clinical manifestations, and pathologic conditions that affect the hypoglossal nerve in its five segments will be reviewed.
Approach/Methods
An understanding of the intracranial and extracranial components of the hypoglossal nerve is fundamental in

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

the evaluation of its pathology. A discussion of anatomy and the diseases that affect the nerve throughout its course from the medulla to the tongue will ensue.
Findings/Discussion
Dysfunction of the hypoglossal nerve may be a consequence of supranuclear, nuclear or infranuclear disease. The cortical center for lingual movement is located within the precentral gyrus, which sends fibers to the hypoglossal nucleus. The paired hypoglossus nuclei are located on the floor of the fourth ventricle within the medulla. The nuclear and infranuclear hypoglossal nerve can be divided into five segments: the medullary, cisternal, skull base, nasopharyngeal/oropharyngeal carotid space and sublingual segments. In evaluating the hypoglossal nerve, a segmental approach should be taken when assessing for nuclear and infranuclear involvement. Specific symptoms and findings related to tongue movement can be based in the specific location of the lesion. Hemiatrophy and weakness of the tongue can result in visible tongue deformity which can be recognized by the patient. In the clinical evaluation of the hypoglossal nerve, the clinician inspects the tongue to search for both difficulties in protrusion as well as any deviation of the tongue. The tongue deviates towards the side of weakness. A bilateral supranuclear lesion will result in a spastic tongue that cannot be protruded. A unilateral supranuclear lesion will cause the tongue to deviate away from the side of the lesion. A nuclear lesion causes the tongue to deviate toward the lesion. An infranuclear lesion distal to the C1 anastomosis has similar findings, but also produces involvement of the infrahyoid strap muscles. Tongue denervation in MRI can be viewed as chronic, subacute or acute. The radiologic findings of fatty infiltration and atrophy of the tongue may be the first clue that a hypoglossal process is present. In acute/subacute stage, abnormal enhancement, increased volume and T2 hyperintensity are present. In the early chronic stage there are changes of fatty replacement without loss of volume/atrophy. In the chronic stage there is extensive fatty replacement and loss of volume.
Summary/Conclusion
The hypoglossal nerve is the motor supply to the tongue. In order to create the most efficient imaging strategy one must be familiar with the anatomy of the hypoglossal nerve and the diseases that affect the nerve throughout the course from the medulla to the tongue.

Three-Year Experience Using Cone Beam Computed Tomography in Temporal Bone Imaging

Kelly, H. R.[1,2]·Curtin, H. D.[1]
[1]Massachusetts Eye and Ear Infirmary, Boston, MA,
[2]Massachusetts General Hospital, Boston, MA.

Purpose
To review three years of experience of cone beam computed tomography (CBCT) in temporal bone imaging as utilized in a subspecialty hospital.
Approach/Methods
Cone beam computed tomography is an emerging technique with the ability to image fine bony structures with high spatial resolution and with the potential for lower radiation doses compared to conventional CT scans. Minimal data is available in the literature regarding the use of this technique in the temporal bone, with the majority of reports focused on cadaveric studies. All temporal bone studies performed on a 3D CBCT system (3D Accuitomo, J Morita Manufacturing) over a three-year period (400 total examinations) at a subspecialty eye and ear hospital were reviewed. Typical clinical indications, imaging findings and estimated radiation doses will be discussed, as will potential artifacts and problems faced with incorporating the system into the daily workload.
Findings/Discussion
In our opinion, CBCT in the temporal bone is particularly useful in evaluation of conductive hearing loss given its ability to clearly image the bony anatomy of the middle and inner ear, including the ossicles, oval and round windows and facial nerve canal. We also are inclined to use CBCT over conventional CT for evaluation of superior semicircular canal dehiscence. Examples of other entities diagnosed by CBCT will be provided, including otosclerosis, congenital ossicular anomalies, ossicular prostheses, bony erosions in the setting of cholesteatoma, spontaneous and postoperative tegmen defects and dehiscence of the facial nerve canal. Acquisition time for CBCT is longer than conventional CT, making CBCT more susceptible to motion artifact, the most common technical limitation that can interfere with diagnostic interpretation. Acquisition also places greater demands on the CT technologists, who must be trained in the new technique and typically spend more time performing a CBCT than a conventional CT of the same area. A “ghosting artifact” was present at times in the middle ear which can simulate soft tissue. While CBCT could theoretically provide high-resolution evaluation of inner ear congenital anomalies in children with sensorineural hearing loss, issues with upright acquisition and motion artifact currently preclude routine use of CBCT over conventional CT in younger pediatric patients. The radiation dose estimates for CBCT in the temporal bone are less than conventional CT, especially if only one side is evaluated.
Summary/Conclusion
Cone beam computed tomography may have advantages

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

over conventional CT scans in certain pathologic entities in the temporal bone due to its high spatial resolution and capacity for depicting the fine bony structures. An understanding of the advantages as well as technical factors/limitations associated with this technique allow the head and neck radiologist to stratify patients to CBCT or conventional CT based on the clinical indication, patient history and age.

Current Review of Treatment Strategies of Carotid Cavernous Fistulas

Trinh, V.·Chao, K.
Kaiser Permanente Los Angeles Medical Center
Los Angeles, CA.

Purpose
Carotid cavernous fistulas (CCFs) typically are classified as high flow/direct fistulas usually related to trauma or aneurysmal rupture or low flow/indirect fistulas secondary to spontaneous formation of dural fistulas. The educational abstract reviews the different treatment strategies regarding high and low flow CCFs primarily via arterial or venous endovascular approaches; however, with discussion of novel neurointerventional approaches notably through the foramen ovale in difficult situations in which endovascular access is not possible. Non-neurointerventional treatments including surgery and stereotactic radiosurgery also will be briefly mentioned. In regards to each treatment we will discuss the inherent risks of hemorrhage or other procedural complications and also the efficacy rates and/or need for reintervention when possible.
Approach/Methods
Review of the current literature and case series with longitudinal followup presented if available.
Findings/Discussion
The treatment of high flow direct fistulas is warranted given the typical earlier signs and clinical symptoms related to cranial nerve palsies, exophthalamos, or chemosis thought secondary to more acute venous hypertension. Endovascular approaches have long been utilized and historically an arterial approach using detachable balloons was considered the standard of care as of the 1980s. However problems arose including early detachment, deflation, or balloon rupture which led to the discontinuation in the U.S. market in 2003. Currently, there is wide acceptance in the use of liquid agents such as onyx, detachable coils, and endovascular stent graft placement with great success. Depending on the size of fistulous connection, covered stents, flow diverting stents, or porous stent-assisted coiling also are considered and now reported. Alternatively, a transvenous approach typically posteriorly through the internal jugular vein and inferior petrosal sinus are viable options. Often times the inferior petrosal sinus may be occluded and other avenues of venous access including through the ipsilateral superior petrosal sinus, facial vein, or superior ophthlamic vein through direct stick or surgical approach. In situations where no endovascular access is possible or safe, we have demonstrated a percutaneous approach through the foramen ovale to be an additional possible treatment approach to CCFs. Indirect CCFs may be asymptomatic and also can resolve on their own. In the absence of symptoms, the best treatment is considered to be conservative management. Current literature suggests that with the advent of ocular symptoms in indirect CCFs, the transvenous route of treatment is preferred for indirect fistulas given greater safety and efficacy.
Summary/Conclusion
Carotid cavernous fistulas have long been treated with great efficacy utilizing an endovascular approach. The goal in the treatment of carotid cavernous fistulas is to occlude the fistula and avoid occlusion of parent vessels, notably the native internal carotid artery. Knowledge of the type of fistulous connection and severity of the symptoms will help make an appropriate treatment decision. Understanding alternative venous approaches may assist in difficult cases. Finally, novel approaches for the treatment of CCFs such as a percutaneous approach through the foramen ovale also may be considered if an endovascular approach or open surgical approach are not feasible options.

EdE-67

Percutaneous Access of the Superior Ophthalmic Vein in the Treatment of Carotid Cavernous Fistulae

Scott, C. J.·Heran, M. K. S.·McNeill, G. J.
Vancouver General Hospital
Vancouver, BC, CANADA.

Purpose
To illustrate a safe percutaneous method of accessing the superior ophthalmic vein to treat carotid cavernous fistulae.
Approach/Methods
We present four cases of carotid cavernous fistulae treated via percutaneous superior ophthalmic venous (SOV) approach. Access was performed using sonographic guidance in two of the cases. In the other two, sonographic-guided puncture was difficult and access was achieved using biplane angiographic roadmap technique. In all four cases, a micropuncture (Cook Medical, Bloomington, IN) kit was used for access and the four French sheath of the kit used as a working sheath for microcatheter access. In all four cases, coil embolization was performed of the carotid cavernous fistula with satisfactory angiographic result at completion. There were no significant orbital bleeding complications.
Findings/Discussion
Venous access to the cavernous sinus in the treatment of carotid cavernous fistulae typically is performed from a femoral approach when there is a patent inferior petrosal sinus. In cases where this approach is not possible, the SOV is a well recognized alternative approach. Traditionally, access to the SOV is achieved via surgical exposure and cannulation or via external jugular venous approach to the facial venous system. We have found that percutaneous access to the SOV is a safe and less invasive alternative. If able to be visualized by ultrasound, this is our preferred approach. In two of the cases, the arterialized vein was difficult to puncture in the supra-orbital region. In these cases using a biplane roadmap technique, percutaneous access was still possible.
Summary/Conclusion
Percutaneous puncture of the superior ophthalmic vein offers a safe and less invasive alternative to surgical exposure in the treatment of the carotid cavernous fistulae that cannot be accessed via traditional transvenous approach.

Intra-Arterial Carotid Imaging with Optical Coherence Tomography

Bhojwani, N.·Blackham, K.
University Hospitals Case Medical Center
Cleveland, OH.

Purpose
Optical coherence tomography (OCT) has recently been gaining recognition for assessment of atherosclerosis and treatment planning in the carotid circulation. The purpose of this exhibit is to concisely explain the technology and describe the potential benefits of OCT intravascular imaging of the carotid arteries and even the intracranial circulation.
Approach/Methods
We will present a concise review of the relevant OCT literature and underlying principles of the technology extrapolated from use in coronary imaging. The neuroradiologist and neurointerventionalist can provide more detailed and accurate diagnoses owing to the technical advantages relative to other modalities which, in turn, more accurately guides proper treatment. Like any type of imaging, inherent pitfalls and artifacts are present. Images will be provided from neurointerventional cases.
Findings/Discussion
Multiple modalities exist for carotid artery imaging such as intravascular ultrasound, catheter angiography, MRI, and CT. However, optical coherence tomography (OCT) provides superior resolution imaging of luminal arterial anatomy. Optical coherence tomography provides tissue resolution of up to 10 microns and, in addition, allows tissue characterization capabilities of different types of plaque and thrombus such as discernment between red and white thrombus, between plaque and neointimal hyperplasia and delineation of atherosclerotic ulceration. Vessel geometry can be obtained and stent assessment performed. Future advances of the technology include functional assessment with contrast enhancement and molecular OCT. Detection of Doppler-like signals would permit physiologic measurement.
Summary/Conclusion
Neuroendovascular OCT is a relatively new application of a technology already employed in cardiac imaging. Because of the high resolution and characterization capabilities, this modality can provide unparalleled detailed carotid imaging allowing for accurate diagnoses and superior guidance of neuroendovascular treatment. Optical coherence tomography is an important modality to become familiar with, since the technology has potential to become more widely used in the near future.

Embolic Protection Devices during Carotid Artery Endovascular Intervention

Bhojwani, N.·Blackham, K.
University Hospitals Case Medical Center
Cleveland, OH.

Purpose
Periprocedural athero and thromboembolic events are common complications resulting from endovascular treatment of carotid occlusive disease. Preventing such complications can be aided with embolic protection devices (EPD) of several types: distal protection in the form of balloon occlusion or filter, and proximal protection in the form of circulatory control devices. The purpose of this exhibit is to concisely delineate the different mechanisms of protection, which are considered a required component of carotid stenting.
Approach/Methods
We will review the three types of embolic protection devices in regard to available models, methods of use, advantages and disadvantages, and reported complications. The evidence basis for the use of these devices from the literature also will be reviewed. Example neurointerventional cases will be showcased to demonstrate application of use.
Findings/Discussion
Embolic protection devices are mandated by the Center for Medicare and Medicaid services during carotid artery stenting (CAS) in order for proper reimbursement. This decision is based not upon large randomized trials but upon a wealth of observational data and pooled results of small studies resulting in a consensus among experts suggesting that embolic protection devices can reduce the risk of stroke during CAS. Complications of embolic protecton devices include vasospasm, ischemia, and infarct. Disadvantages include cerebral flow impedance, trauma to vessel intima, vasospasm, and particle escape. Each device indication depends upon the difficulty in crossing the lesion, complexity of preparation, and safety of deployment. All the current designs are limited by severely stenotic lesions, tortuous vessels, and contralateral lesions. While there is no perfect EPD that can prevent all neurologic complications, the choice of EPDs should depend on the patient's anatomy and the operator's comfort.
Summary/Conclusion
Multiple embolic protection devices exist to decrease complications during endovascular treatment of carotid atherosclerosis with carotid artery stenting. Each device poses varying advantages and indications. Device complications and limitations are inherent of all three types.

MR Imaging and CT Findings on Postintervention Imaging after Mechanical Thrombectomy for Acute Ischemic Stroke

Jones, J. G. A.·Rastogi, S.
University of California Los Angeles
Los Angeles, CA.

Purpose
Mechanical thrombolysis for acute ischemic stroke is becoming increasingly more common. At our institution, we routinely obtain postintervention CT and MRI of the brain to evaluate both the results of the treatment as well as its complications. Several interesting and clinically relevant findings may be appreciated on a detailed analysis of the postoperative imaging based on the degree of recanalization, timing of recanalization, and the findings on the preintervention imaging.
Approach/Methods
We reviewed our institutional stroke database over the past ten years to identify cases demonstrating both typical and atypical postintervention findings on MRI and CT and correlated them with clinical presentation, preoperative imaging, timing of recanalization, degree of recanalization and patient outcomes.
Findings/Discussion
We will review several examples of contrast staining on CT and correlate them with MRI to demonstrate the difficulty of differentiating contrast staining on postoperative CT versus hemorrhage. The clinical significance of distinguishing between iodinated contrast and acute blood cannot be understated. We also will review the imaging findings indicating persistent vascular occlusion and ischemia such as: intravascular FLAIR hyperintensity, arterial GRE hypointensity indicating persistent thrombus and venous GRE hypointensity indicating persistent maximum oxygen extraction from ischemic tissue. We also will review postintervention MR perfusion findings demonstrating infarction, ischemia and luxury reperfusion. Lastly, we will discuss and demonstrate examples of FLAIR CSF hyperintensity seen in some cases postmechanical intervention known as hyperattenuation acute reperfusion marker (HARM).
Summary/Conclusion
This exhibit will increase the familiarity of radiologists with typical and atypical findings on the postoperative imaging findings on CT and MRI after mechanical intervention.

Early MR Imaging Evaluation of Suspected Nonaccidental Brain Injury

Palasis, S.·Messner, S.·Hayes, L. L.·Grattan-Smith, D.
Children's Healthcare of Atlanta
Atlanta, GA.

Purpose
To illustrate the benefit of performing early brain and cervical spine MRI for improved diagnosis and timing of injury in suspected nonaccidental trauma.
Approach/Methods
We have implemented a new nonaccidental trauma (NAT) protocol in cases of suspected child abuse and brain injury. The protocol consists of routine spin-echo imaging sequences, DTI, SWI, and fat saturated c-spine imaging. The goal was to perform the NAT protocol as soon as possible after arrival of the child to the emergency department and then perform a follow-up MRI within 10 days.
Findings/Discussion
The detection of nonaccidental brain injury rests heavily on neuroimaging. The recommendation of the American College of Radiology (ACR) and the American Academy of Pediatrics (AAP) has been to reserve early brain MRI for cases where the CT is abnormal or when abnormal neurologic findings are present and to perform cervical spine MRI only if there are clinical findings to suggest injury. Neurologic symptoms of trauma are not always readily obvious in the neonate/young infant and CT is often nonrevealing. The advent of new sensitive MR techniques have remarkably improved the sensitivity of MRI to early intracranial injury. We have found that MRI also can be useful in grossly estimating the timing of injury, mainly through detection of acute neuronal injury and delayed secondary neuronal injury using DTI. The identification of soft tissue edema in the cervical spine can refocus the imaging differential to trauma if the intracranial findings are indeterminate or in dispute.
Summary/Conclusion
We have found that the NAT protocol now being utilized at our institution has added new imaging information that is useful for detection of early intracranial injury and has helped with more accurate timing of the insult. Our exhibit will illustrate our experience since the implementation of this new protocol.

EdE-73

Revisiting Arachnoid Cyst: Atypical Imaging Findings, Unusual Presentation and Rare Complications

Ramakrishnaiah, R.·Schultz, K.·Samant, R.·Fitzgerald, R.·Burgin, K.·Hegde, S.·Van Hemert, R.·Angtuaco, E.
University of Arkansas for Medical Sciences
Little Rock, AR.

Purpose
Arachnoid cysts are common intracranial space-occupying lesions which are diagnosed incidentally on imaging studies. Arachnoid cysts typically present as extra-axial thin-walled cystic lesions which follow CSF signal intensity on all MRI sequences. Atypical presentation and complications of arachnoid cysts are relatively uncommon. The purpose of this scientific exhibit is to provide a pictorial review and discussion of unusual presentation and complications of arachnoid cysts in children.
Approach/Methods
Imaging studies of arachnoid cysts in children with unusual presentation or rare complications that having clinical significance and educational value will be selected from the extensive database of a tertiary care pediatric hospital over a period of eight years (2004 to 2012).
Findings/Discussion
A detailed pictorial review using high-resolution images and a brief discussion will be displayed under the following headings: 1. Complication and spontaneous variation of imaging characteristics: Rapid growth, spontaneous rupture, intracystic hemorrhage, spontaneous focal meningeal enhancement, subdural hygroma, raised intracranial pressure, obstructive hydrocephalus, encephalomalacia and significant bone remodeling occurring in association with arachnoid cysts. 2. Arachnoid cysts associated with other brain and spine lesions: schizencephaly, corpus callosal agenesis, Chiari I malformation, absent septum pellucidum, optic nerve hypoplasia, and multiple lateral spinal meningoceles. 3. Unusual location: Cyst of liliequist membrane, intraventricular cysts within the lateral, third and fourth ventricles, superior cerebellar cistern, ambient cistern, velum interpositum, septum pellucidum and spinal arachnoid cysts. 4. Miscellaneous: fetal arachnoid cyst, post-fenestration recurrence and arachnoid cyst CSF

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

dynamics. 5. Differential diagnosis and cystic lesions mimicking arachnoid cyst.
Summary/Conclusion
Arachnoid cysts are common space-occupying lesions encountered in neuroimaging practice. Atypical presentation and complications of arachnoid cysts are relatively uncommon. But, a strong knowledge of rare and atypical imaging features of a common disease entity is necessary for accurate diagnosis, avoid potential pitfall, preempt unforeseen complication and improves patient management.

Embryology and Imaging of Developmental Maxillofacial Anomalies: A Pictorial Review

Ramakrishnaiah, R. H.·Honnebier, B.·Kumar, M.·Samant, R.·Hegde, S.·Fitzgerald, R.·Van Hemert, R.·Angtuaco, E.
University of Arkansas for Medical Sciences
Little Rock, AR.

Purpose
Congenital maxillofacial anomalies are associated with a variety of syndromes that are encountered not infrequently in clinical practice. Imaging of those anomalies using high-resolution maxillofacial CT scan plays a key role in characterization of different bony dysplasia and in presurgical planning. The purpose of this scientific exhibit is to provide a pictorial review of embryogenesis of facial bones with brief discussion of various syndromes associated with maxillofacial anomalies and their associated imaging findings as well as imaging findings of isolated and syndromic maxiollofacial anomalies in children.
Approach/ Methods
Imaging studies of children with maxillofacial anomalies will be reviewed retrospectively and through an extensive data base search of a tertiary care pediatric hospital. All children were referred for imaging by the maxillofacial surgery division for presurgical assessment.
Findings/Discussion
A pictorial review would include a brief description of relevant embryology followed by a detailed description of characteristic imaging features. The imaging findings will be discussed with high-resolution multiplanar CT and MRI images. The following syndromes with maxillofacial anomalies and nonsyndromic isolated maxillofacial anomalies will be discussed: Nager syndrome, Pierre Robin syndrome, Parry-Romberg, Pfeiffer syndrome, Treacher Collins syndrome, Crouzon syndrome, Gorlin syndrome, Apert syndrome, external auditory canal atresia, maxillary hypoplasia, bilateral cleft lip, congenital facial defect, mandibular anomalies, hemifacial hypoplasia, dentofacial functional abnormalities, anodontia, hemifacial microsomia, microtia, choanal atresia, anopthalmia, and solitary central maxillary incisor syndrome.

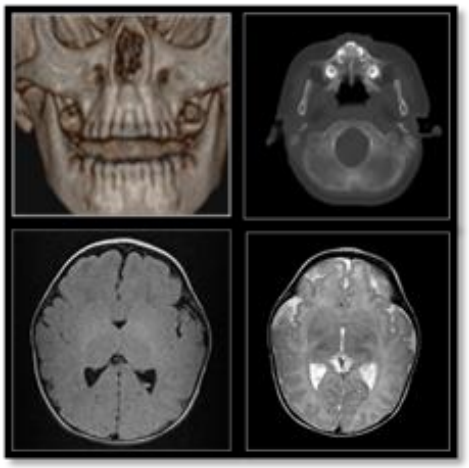

Figure: Patient with solitary midline maxillary incisor with an azygous anterior cerebral artery and lobar holoprosencephaly.
Summary/Conclusion
Maxillofacial anomalies are not infrequently encountered in neuroimaging practice. Knowledge of the different syndromes and their associated imaging findings is important for accurate assessment and better surgical planning and outcome for the patients.

KEYWORDS: Congenital anomalies, Face, syndromic maxillofacial anomaly

EdE-75

Thrombosis of Developmental Venous Abnormalities: Case Series and Review

Baradaran, H.·Tsiouris, A. J.
Weill Cornell Medical College
New York, NY.

Purpose
Developmental venous anomalies (DVA) are one of the most commonly encountered vascular malformations with an overall incidence of 2-4% of the population. While they are usually asymptomatic and incidental findings, rare complications are possible such as hemorrhage, nonhemorrhagic ischemia, or thrombosis of a draining vein. Thrombosis of a draining vein is very rare with less than 30 cases reported in the literature. Here, we present five cases of thrombosis of a draining vein in symptomatic pediatric patients.
Approach/Methods
A literature search of cases of thrombosis of developmental venous abnormalities was performed and relevant case reports were reviewed. The clinical histories and representative imaging findings for the five patients seen at our institution were reviewed. All five patients had MRI examinations. Of the five patients, one had a thrombosed DVA in the posterior fossa, two in the temporal lobe, and two in the frontal lobe.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Findings/Discussion
We have five pediatric patients with complete or partial thrombosis of a draining vein in a DVA. The most severe case involved a large DVA in the left temporal lobe of a 12-year-old male. In this patient, there is a large collecting vein with intraluminal T1 hyperintensity, T2 hypointensity, and blooming artifact on susceptibility-weighted images with surrounding vascular structures consistent with thrombosis of a collecting vein of a large DVA. While this was the most obvious case, there were several other more subtle cases which demonstrated similar findings with areas of T2 hypointensity, T1 hyperintensity with blooming artifact on susceptibility-weighted images. In one case, the thrombus itself is not seen but an area of hemorrhagic infarction is seen with adjacent small enhancing vessels thought to be a DVA, so thrombosis of a draining vein was suspected.
Summary/Conclusion
The ability to recognize thrombosis of developmental venous anomalies is essential for appropriate treatment of symptomatic pediatric patients. When abnormalities do not conform to a vascular territory, thrombosis of DVA should be on the differential and should not be mistaken for a mass lesion. Recognizing these findings is essential to ensure appropriate treatment is initiated and further venous infarction is prevented if possible.

KEYWORDS: Developmental venous anomalies, Thrombosis

EdE-76

"What Lies Beneath": A Multimodality Approach to Imaging Congenital Spine Pathology Underlying Lumbosacral Cutaneous Lesions

Fox, L.·Li, S.
Baystate Medical Center
Springfield, MA.

Purpose
Children are commonly referred for imaging when a skin lesion is discovered in the lumbosacral region on physical examination because of the concern for underlying spinal malformations. The association exists because both skin and nervous tissue originate from ectoderm. The purpose of this exhibit is to review the imaging findings of congenital anomalies underlying midline lumbosacral cutaneous lesions (sacral dimple, skin tag, hypertrichosis) in multiple modalities.
Approach/Methods
1. Review of the normal lumbosacral spinal anatomy. 2. Describe the CT, ultrasound, MR, and plain film characteristics of congenital anomalies associated with lumbosacral skin lesions.
Findings/Discussion
Cases will be presented to illustrate imaging features of a broad array of disease entities including tethered cord, diastometomyelia, lipoma, dermal sinus, sacral agenesis, lumbar teratoma, etc. Relevant epidemiology, pathogenesis and clinical features will be discussed.

Summary/Conclusion
A knowledge and understanding of the various congenital spinal diseases affecting the pediatric patient will aid the radiologist in making appropriate and timely diagnoses. At the end of this presentation, the viewer should be familiar with the characteristic clinical and imaging features, epidemiology and pathogenesis of a variety of lumbosacral congenital malformations related to overlying cutaneous abnormalities.

KEYWORDS: Congenital anomalies, Lumbar spine

EdE-77

Imaging Manifestations of Uncommon Variants of Astrocytoma in Children

Stein, J. M.[1,2]·Santi, M.[1]·Vossough, A.[1]·Zimmerman, R. A.[1]·Feygin, T.[1]
[1]Children's Hospital of Philadelphia, Philadelphia, PA,
[2]Hospital of the University of Pennsylvania, Philadelphia, PA.

Purpose
The purpose of this presentation is to review uncommon imaging manifestations of astrocytoma in children.
Approach/Methods
We present a pictorial review of uncommon imaging manifestations of astrocytoma in children organized by several distinct locations: the cerebral hemispheres, the ventricles, the pineal region, the posterior fossa and the brainstem. Cases were obtained based on keyword searches of the radiology report database at our institution. Cases presented include MR images obtained at 1.5 or 3T, CT images, and pathologic correlation. Unusual imaging features in each location are identified. Highlights of this review include two cases of infantile astrocytomas with extensive leptomeningeal spread and multicystic involvement of the cerebral hemispheres mimicking congenital developmental anomaly or cerebral infarction, gliomatosis cerebri mimicking cortical dysplasia or inflammatory demyelination, exophytic astrocytoma at the cerebellopontine angle mimicking medulloblastoma or atypical teratoid-rhabdoid tumor, and exophytic brainstem

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

astrocytoma mimicking ependymoma.
Findings/Discussion
Astrocytoma represents the most common type of primary central nervous system neoplasm in children and adults. Unusual manifestations of astrocytoma can mimic the typical appearances of more rare tumor types. A cystic appearance is a commonly recognized manifestation of pilocytic astrocytomas and pleomorphic xanthoastrocytomas. Infantile astrocytomas can have such an extensive infiltrative multicystic appearance that they may mimic developmental anomalies and infarct. Tumors that appear extra-axial, particularly in the posterior fossa, can represent exophytic astrocytomas. In our experience, high-resolution imaging sequences such as constructive interference in steady state (CISS) obtained in multiple planes can be helpful in identifying an attachement site to the adjacent cerebellar hemisphere or brainstem in these cases.
Summary/Conclusion
Astroctyomas can have diverse and unusual imaging manifestations and mimic more rare tumors. Imagers should be aware of these unusual manifestations, and astrocytoma should almost always be considered in the differential diagnosis of neoplasms at most intracranial locations in children.

KEYWORDS: Pediatric neoplasms, Astrocytoma

EdE-78

Pediatric Pineal Lesions: A Pictorial Review

Fang, A.·Meyers, S.
University of Rochester Medical Center
Rochester, NY.

Purpose
Pineal tumors are relatively rare tumors of the central nervous system and account for 3-8% of intracranial neoplasms in the pediatric population. The purpose of this educational poster is to highlight the anatomy and embryology of the pineal gland, as well as the pathology and characteristic imaging features of pineal lesions in pediatric patients.
Approach/Methods
A variety of pineal lesions will be presented illustrating their unique histology and imaging appearance on computed tomography (CT) and magnetic resonance imaging (MRI).
Findings/Discussion
This educational exhibit will discuss the differential of pineal region lesions including pineal parenchymal tumors, germ cell tumors, metastasis, and other pineal region masses arising from cell types adjacent to the pineal gland. The clinical and pathologic features of pineal lesions will be described. For each pineal region mass of varying origin, the unique imaging characteristics will be illustrated. A brief review of the therapeutic management of pineal lesions will be provided.
Summary/Conclusion
Lesions of the pineal gland can represent a variety of benign and malignant disease conditions. Knowledge of the clinical and pathologic features, and unique imaging characteristics of varying lesions, can assist in refining the differential diagnosis and help optimize patient treatment.

KEYWORDS: Pineal gland

EdE-79

MR Imaging Assessment of Cerebospinal Fluid Hydrodynamics with a Specific Focus on Children with Hydrocephalus

Hassan, E.·Cain, J.·Stivaros, S. M.
University of Manchester
Manchester, UNITED KINGDOM.

Purpose
There is much that we do not understand with regards to the pathophysiology of pediatric hydrocephalus. As a consequence our current clinical radiologic techniques for the assessment of hydrocephalus, such as the measurement of ventricular size/indices or the subjective assessment of cine phase contrast MRI, can be found lacking. Recent developments in advanced MRI-based perfusion and flow quantification techniques, such as phase contrast MRI (PCMRI) can be used to further our understanding of cerebrospinal fluid (CSF) flow in both normal and pathophysiologic states. These techniques are vital if we are to further our understanding of this disease process.
Approach/Methods
The exhibit will describe the prevalence and current understanding of the pathophysiology of pediatric hydrocephalus including a review of the literature on CSF pulsewave encephalopathy. We will provide a summary of current treatment and monitoring options as well as the current routine use of MRI in pediatric hydrocephalus diagnosis and assessment. In addition we will include an overview of the more advanced noninvasive MRI methodologies which have applications in CSF flow research, namely quantitative PCMRI. There with be an emphasis on the role of these techniques in the quantitative assessment of cerebral hemo/hydro dynamics, which can provide unique information regarding CSF flow in a variety of pathologic processes such as hydrocephalus. The exhibit also will cover the use of PCMRI in the premorbid and post-treatment assessment of third ventriculostomy for the management of children and adults with hydrocephalus.
Findings/Discussion
In order to develop an advanced understanding of CSF flow in children, comprehension must be gained about the complex physiologic mechanisms that exist in cerebral hydrodynamics. Using methodologies such as quantitative PCMRI, radiologic research is challenging some of the classical assumptions regarding CSF production and

absorption in children as well as adults. For example it has been postulated that some of the secretion of CSF must arise from the capillary bed through passive filtration, as the choroid plexus is unable to supply all of the fluid required to replace all of the CSF. In addition we are beginning to understand that CSF absorption may not in fact predominate across the arachnoid granulations, but be a process akin to the absorption of plasma filtrate through the subarachnoid capillaries.
Summary/Conclusion
Quantitative MRI methodologies now allow clinicians and researchers the ability to manage children more efficiently, with fewer invasive procedures. These methodologies also may be able to answer fundamental questions about the effect of hydrocephalus on cerebral perfusion. This exhibit will provide a summary of these methodologies and how they can be used in current clinical and research applications. In addition it is intended that this educational exhibit will provide the reader with the information necessary to guide them towards undertaking such imaging in both the clinical and academic settings, in what is undoubtedly an exciting clinical domain.

KEYWORDS: Hydrocephalus, Phase contrast imaging

EdE-80

Vascular Anomalies of the Head and Neck in Patients with Velocardiofacial Syndrome

Nayyar, R.·Das, K.·Nayyar, S.·Tatum, S. A.·Marrinan, E. M.·Swarnkar, A. S.
SUNY Upstate
Syracuse, NY.

Purpose
The purpose of our exhibit is to demonstrate the head and neck vascular abnormalities in patients with velo-cardio-facial syndrome (VCFS) and the importance to recognize these abnormalities for surgical planning. Our study is a review of 50 patients with velo-cardio-facial syndrome, with both a radiologists' perspective and otolaryngologists' perspective of the importance of these vascular abnormalities.
Approach/Methods
This is an IRB-approved, retrospective study of 50 patients with VCFS who underwent a MRA of the brain and neck.
Findings/Discussion
The study is currently ongoing; however, preliminary data demonstrates significant abnormalities of the carotid and vertebral arteries on the MRA examination. Medial displacement of the internal carotids, low carotid bifurcations, hypoplastic vertebral arteries, and tortuous or kinked internal carotids were common anomalies. The vascular abnormalities influence the surgical approach. Our discussion section will include images of these anomalies as well as a table tabulating the different anomalies. We also will have an otolaryngologist describe how these anomalies change his surgical approach and the importance of preoperative MRA examinations.
Summary/Conclusion
In summary, we will present and demonstrate the most common vascular abnormalities in patients with VCFS. The study is currently ongoing; however, preliminary data demonstrates a high percentage of an anomalous course of the internal carotid arteries. This presents a major risk for pharyngeal flap surgery. Our exhibit will demonstrate the importance of preoperative MRA examination for detecting these anomalies from both a radiologists and facial plastic surgeon's perspective.

Diagnostic Carotid Angiography CPT Codes Have Been Revised, and You Will Be Reimbursed Less: Why, How, and How Much

Donovan, W. D.[1]·Nicola, G. N.[2]·Bello, J. A.[3,4]·Hirsch, J. A.[5,6]·Tu, R. K.[7]·Morrow, M. J.[8]
[1]William W. Backus Hospital, Norwich, CT, [2]Hackensack University Medical Center, Hackensack, NJ, [3]Albert Einstein College of Medicine, The Bronx, NY, [4]Montefiore Medical Center, The Bronx, NY, [5]Massachusetts General Hospital, Boston, MA, [6]Harvard Medical School, Boston, MA, [7]Progressive Radiology, Washington, DC, [8]ASNR, Oak Brook, IL.

Purpose
Discuss why the cervicocerebral catheter angiography set came to be revised. Estimate the reimbursement impact of the carotid angiography code set revision and new valuation.
Approach/Methods
Review the CPT-RUC system that identified the carotid

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

angiography codes as "potentially misvalued." (CPT = Current Procedural Terminology; RUC = Relative Value Scale Update Committee). Review the component coding scheme that previously described some typical carotid angiography procedures. Enumerate the new code structure. Describe the valuation process for the new codes: RUC review, CMS Final Rule. (CMS = Centers for Medicare and Medicaid Services, or Medicare).
Findings/Discussion
The component coding structure for reporting interventional procedures has been formally in place since 1992, with the advent of the RBRVS (Resource-Based Relative Value Scale). This system allowed detailed identification of a catheter angiography procedure by means of specific CPT codes for purposes of billing, research, resource allocation. Over the past few years, component coding has been increasingly marginalized through the concerted efforts of CMS, the RUC, and its subcommittee, the RAW (Relativity Assessment Workgroup). These efforts were rationalized as a means to achieve "efficiencies" in procedural reimbursement. Numerous radiologic supervision and interpretation (S&I) codes were identified as "potentially misvalued" through the "codes performed together" screen created by CMS. Creation of bundled codes was "recommended" through a joint CPT/RUC workgroup -- without workable alternatives. ASNR CPT physicians and staff participated in the creation of the new bundled code set. ASNR RUC physicians and staff participated in the RVU (relative value unit) valuation of the new code set. The RUC recommended values less than the involved societies requested; CMS decided to decrease those values further. The new codes are described, highlighting the changes from the previous system. Estimates of the RVU value and professional reimbursement for several representative cervicocerebral procedures will be provided.
Summary/Conclusion
Radiology societies have been compelled by CMS to rework component codes into bundled code sets. This has typically resulted in a decrease in RVU value, and the new carotid angiography codes are no exception. At abstract deadline, we estimate that the professional reimbursement for a typical carotid or vertebral diagnostic angiography procedure will be reimbursed 10-40% less than in 2012. Once CMS reimbursement policy is finalized for 2013, more
specific estimates of expected revenue decrease will be generated.

KEYWORDS: Medicare, Carotid angiography, vertebral angiography

EdE-82

ASNR at the RUC: A Case Study in Devaluation

Donovan, W. D.[1]·Barr, R. M.[2]·Silva, E.[3]·McGinty, G.[4]
[1]William W. Backus Hospital, Norwich, CT, [2]Mecklenburg Radiology, Charlotte, NC, [3]South Texas Radiology Group, San Antonio, TX, [4]NRAD Medical Imaging, Garden City, NY.

Purpose
Describe the Medicare RBRVS (Resource-Based Relative Value Scale) valuation process, using the complex example of recent revaluation of spine CT.
Approach/Methods
Review the mechanics of the RBRVS and the RUC (AMA/Specialty Society RVS Update Committee). Describe Medicare's recent attempts to target radiology CPT (Current Procedural Technology) code valuations, including the actions of the RAW (Relativity Assessment Workgroup). Using spine CT as an example, review ASNR's involvement in the identification of particular codes for review and preparation of RUC survey results for the thrice-yearly RUC meetings. Describe the process whereby RUC recommendations are assessed and sent to CMS (Centers for Medicare and Medicaid Services), and judged for the Final Rule. Describe the appeal process, and ultimate result.
Findings/Discussion
Spine CT represents a comprehensive example of the convoluted system for CMS reimbursement decisions. Cervical and lumbar spine CT exams were identified by the RAW as "potentially misvalued," meeting criteria as one of the "fastest-growing" procedures in the RUC database. Interested societies (including ASNR and ACR) were invited to present recommendations to the RUC as to the appropriate valuation of these procedures. ASNR and ACR conducted random surveys of their membership for the October 2009 RUC meeting. The societies recommended an increase in the then-extent RVU (Relative Value Unit) values of these procedures (as well as for thoracic spine CT); those RVU values dated back to the institution of the RBRVS in 1992. After vigorous discussion, the RUC recommended maintenance of the existing values. CMS disagreed with the decision of the RUC, and published a decrease in the RVU values of these procedures in the Final Rule. Radiology appealed the decision, which went to a CMS Refinement Panel for adjudication. This resulted in an increase in the RVU value for cervical spine, but not for thoracic or lumbar, instituted for the 2012 calendar year.
Summary/Conclusion
In recent years, CMS has pursued several strategies to decrease radiologists' reimbursement. Identification of "potentially misvalued" services is one method; interested societies are compelled to expend resources and ASNR physician volunteers' free time to seek appropriate valuations for the services its members provide. Even in the case of a straightforward diagnostic procedure, the elaborate system by which Medicare assigns RVUs to individual CPT codes can confound the hardiest payment

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

policy veterans. The RUC survey process is the fundamental keystone of ASNR's efforts to achieve satisfactory valuation for the services its members provide.

Tuberculous Spondylitis: A Pictorial Review of CT and MR Imaging Findings

Fukutomi, H.[1]·Okada, T.[1]·Oshima, S.[1]·Akasaka, T.[2]·Maekura, T.[1]·Koyama, T.[1]·Shiozaki, T.[1]·Todo, G.[1]·Tomihara, M.[1]
[1]Osaka Red Cross Hospital, Osaka, JAPAN, [2]Kishiwada City Hospital, Osaka, JAPAN.

Purpose
Tuberculous spondylitis requires early treatment since it causes severe deformation of the spine at advanced stages. Understanding of the typical findings of tuberculous spondylitis is clinically important, because the necessary antibiotic differs from pyogenic spondylitis. The purpose of this educational exhibit is to review computed tomography (CT) and magnetic resonance (MR) imaging findings of tuberculous spondylitis.
Approach/Methods
We retrospectively reviewed MR images of eight patients with tuberculous spondylitis (age: 42-88 years, mean: 69 years, five male and three female) diagnosed between 2005 and 2012 in our hospital. CT scans and MRI scans at 1.5T were performed in all patients. T2- and T1-weighted images, STIR (short-TI Inversion Recovery) images, pre and postcontrast fat-suppressed T1-weighted images were obtained.
Findings/Discussion
The etiology of tuberculous spondylitis is hematogenous or lymphatic spread from a pulmonary origin. The initial inoculum usually is located in one of the anterior vertebral bodies. The lesion spreads underneath the longitudinal ligament to adjacent vertebral bodies and more than three consecutive vertebral bodies often are affected (Figure 1). The intervertebral disks often are spared as mycobacterium tuberculosis does not have proteolytic enzymes. Congestion abscess and gravitation abscess are often observed (Figure 2). These abscesses are marked and progress far from the primary lesion, destroying vertebral bodies and presenting with severe symptoms. Calcifications and skip lesions often are observed. The clinical course often is longer than pyogenic spondylitis.

figure1

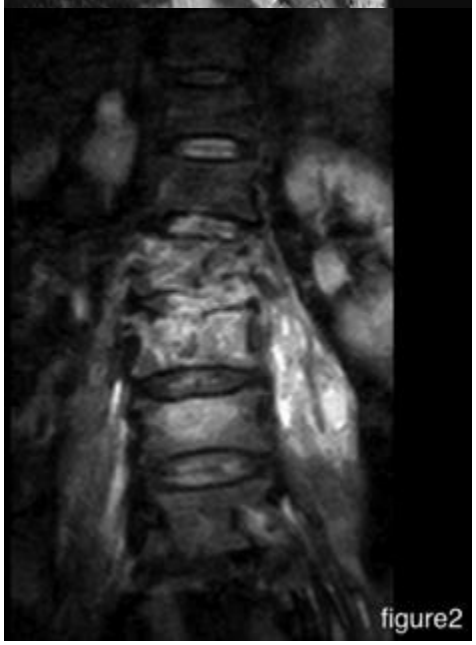

figure2

Summary/Conclusion
Awareness of the disease process and knowledge of the characteristic imaging findings of tuberculous spondylitis

are necessary in order to provide early appropriate treatment and prevent kyphosis.

KEYWORDS: Tuberculosis, Spondylitis

Facet Synovial Cyst Imaging Characteristics and Treatment

Cambron, S. C.·Guerin, S. J.·Pastel, D. A.
Dartmouth Hitchock Medical Center
Lebanon, NH.

Purpose
Lumbar facet synovial cyst formation is an important cause of treatable radiculopathy. Our aim is to present the imaging characteristics of spinal synovial facet cysts with MRI, CT, and CT myelogram. We also will review minimally invasive image-guided intervention of synovial cysts.
Approach/Methods
The imaging characteristics and location of facet synovial cysts of patients that underwent intervention at our institution from 2005-2012 will be reviewed retrospectively.
Findings/Discussion
Over 148 patients have been treated for lumbar synovial cysts at our institution with 199 facet cysts percutaneously. Of these patients, 110 had MR imaging available for review. Images demonstrating the anatomy and variable imaging characteristics of facet cysts on MRI, CT, and CT myelogram will be reviewed including examples of foraminal, lateral recess, central canal and bilateral cysts. Percutaneous treatment options and methods will be illustrated including CT-guided facet joint access and direct access to the synovial cyst with cyst rupture. The appearance of successful rupture also will be demonstrated.
Summary/Conclusion
Lumbar synovial formation is an important cause of treatable radiculopathy. With an understanding of the relevant anatomy and imaging characteristics of synovial cysts they can be successfully diagnosed and treated percutaneously.

KEYWORDS: Facet, CT guidance, synovial cyst

EdE-85

Radiofrequency Ablation of Spinal Metastases

Friedman, J.·Whittemore, A.·Chason, D. P.
University of Texas Southwestern Medical School
Dallas, TX.

Purpose
Spinal metastases are the most common site of osseous metastatic disease with a high incidence among patients with multiple different primary cancers. Treatment is aimed primarily at palliation with the primary goals of durable pain relief and amelioration of pain-related disability. Treatment options for spinal metastases include external beam radiation, chemotherapy, surgery and minimally invasive percutaneous techniques such as radiofrequency ablation.
Approach/Methods
This educational exhibit will serve as a tutorial for fellows and residents to learn how to perform percutaneous RFA of spinal metastatic lesions. The exhibit will discuss basic concepts of RFA as well as highlight newer techniques focused on single needle access that can be done in conjunction with biopsy and/or vertebroplasty.
Findings/Discussion
Learning points: 1. Identify criteria for patient selection, including indications and contraindications for RFA of spinal metastases, based on both clinical data and imaging studies. 2. Illustrate needle placements and approaches used to perform percutaneous RFA of spinal metastases. 3. Discuss the underlying thermal properties of RFA and how to utilize and monitor RFA probes to treat spinal metastases and minimize the risks of thermal injuries. 4. Describe newer devices, including navigational osteotomes and steerable RFA devices, that allow for a single needle approach and integration of concurrent biopsy and/or vertebral body augmentation.
Summary/Conclusion
Awareness of percutaneous RFA will allow training neuroradiologists to expand their services to include palliation of painful metastatic lesions.

KEYWORDS: Spinal instumentation, Spine interventions, spinal metastases

EdE-86

Value of the Epidurogram in Epidural Steroid Injections

Ortiz, A.
Winthrop University Hospital
Mineola, NY.

Purpose
To reinforce the importance of the epidurogram during the performance of lumbar epidural steroid injections.
Approach/Methods
Epidurograms from various lumbar epidural steroid injection procedures performed either through the interlaminar, transforaminal or caudal approaches are reviewed and used to demonstrate the importance of correlating the contrast distribution pattern with the patients' clinical presentation and history, as well as their therapeutic response to the procedure.
Findings/Discussion
The epidurogram should be used not only to confirm the location of the spinal needle tip within the spinal epidural space, but also to estimate the subsequent potential spread of injectate within the epidural space. Clinical scenarios are often encountered in which the distribution of contrast agent within the epidural space may be altered

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

or confined due either to anatomical variation within the epidural space or to alteration of the epidural space by conditions such as lumbar stenosis, exit foramen stenosis, epidural adhesions and prior surgical interventions such as laminectomy or fusion. In these situations, the epidurogram should be evaluated carefully in order to ascertain the probable epidural spread of the subsequent injectate. Furthermore, the epidurogram may raise the possibility of a need for an alternative approach to access the area that correlates with the side and level of a patient's symptomatic presentation. Lastly, the epidurogram may explain why certain approaches result in symptomatic improvement, while other approaches may be associated with treatment failure.
Summary/Conclusion
A properly performed and analyzed epidurogram may facilitate improved patient outcomes following lumbar epidural steroid injection.

KEYWORDS: Epidural space, Anatomy

Notochord: Embryologic Anatomy and Notochord Derived Lesions

Patil, A. A.·Singh, J.·Kocak, M.·Jhaveri, M.·Bhabad, S.·Bachhav, V.
Rush University and Medical Center
Chicago, IL.

Purpose
The lesions of the notochord encompass a spectrum from notochord remnants, benign notochord tumor to aggressive lesions. Imaging plays an important role in lesion characterization and differentiating benign from malignant lesions. The aim of this exhibit is to illustrate the embryology of notochord, spectrum of malignant as well as benign notochord lesions, and anatomical variants.
Approach/Methods
A. Introduction. B. To review the embryologic anatomy of notochord using schematic illustration and CT/MR images. C. To review the imaging features of notochord derived lesions: 1. Clival chordoma, 2. Sacral chordoma, 3. Nasopharyngeal chordoma, 4. Benign notochordal cell tumors (BNCT), 5. Echordosis physilaphora. 6. Thornwaldt cyst, 7. Canalis basalis medianus, 8. Fossa navicularis magna.
Findings/Discussion
Notochord-derived lesions are interesting in terms of their typical location, imaging characteristics, clinical presentation and progression. Benign notochord lesions can be confused for more aggressive lesions.
Summary/Conclusion
An understanding of their typical radiologic appearance, expected location can help avoid unnecessary radiologic investigations and intervention.

KEYWORDS: Embryology, Anatomy, notochord lesions

EdE-88

Pediatric Spine Pathology Revealed with Readout Segmented EPI Diffusion Tensor Imaging

Hayes, L. L.[1]·Jones, R.[1,2]·Palasis, S.[1]·Grattan-Smith, D.[1]
[1]Children's Healthcare of Atlanta at Scottish Rite, Atlanta, GA, [2]Emory University, Atlanta, GA.

Purpose
To illustrate the utility (RS) EPI as a method for diffusion imaging of the spine to detect spinal pathology in pediatric patients.
Approach/Methods
Readout segmented DTI was performed on a 1.5T Avanto and a 3T Trio scanner with seven segments, a parallel imaging factor of 2, a b factor of 500 s/mm^2 and an in-plane resolution of 1.25 mm^2. The b factor was chosen to be lower than that used for studies of the brain to compensate for reduced SNR due to the smaller voxel dimensions used in this study and for a reasonable acquisition time of approximately five min. A sagittal slice orientation was chosen as it allows an entire section of the spine to be assessed with a single acquisition. In our initial studies of the C-spine, we evaluated both gated and nongated versions of the sequence but found that motion/pulsatility produced unacceptable artifacts in some subjects when gating was not used. Gating was used therefore for all subsequent studies. For the C-spine, a single slice was acquired on every third heartbeat and a delay for the peripheral trigger of approximately one third of the cardiac cycle was used. Gating was not used for the T or L spine. This sequence was added to standard protocols for imaging pediatric spines in various pathologic conditions, including drop metastases, spinal cord infarction, epidural abscesses, paraspinal neuroblastoma, bone metastases, and epidermoid cysts.
Findings/Discussion
(RS) EPI produced excellent image quality, nearly free from the artifacts plaguing other types of diffusion imaging of the spine. Traditional artifacts from the surrounding bone and motion of CSF, breathing, and arterial pulsations were drastically reduced, providing good spatial resolution and strong signal, thereby allowing identification of drop metastases from brain tumors such as medulloblastoma and germ cell tumors, some of which were not apparent on T1- and T2-weighted images. Additionally, diffusion-weighted imaging (DWI) was helpful in diagnosing spinal cord infarction, allowing differentiation from bland cord edema. It also was useful in defining the extent of epidural abscesses and helped distinguish them from other epidural collections. Additionally, DWI assisted in defining the margins of paraspinal neuroblastoma and detecting bony involvement. Furthermore, restricted diffusion within a cyst essentially clinched the diagnosis of an epidermoid.
Summary/Conclusion
(RS) EPI is a powerful method for diffusion imaging of the spine. Images presented in this exhibit demonstrate that this technique is exquisitely helpful in the workup of

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

numerous pathologic conditions of the spine affecting children, including tumor, infarction, and infection.

KEYWORDS: Diffusion MR imaging, Pediatric spine

EdE-89

Spinal Extradural Fistula: A Pictorial Review

Chen, D.·Kuo, Y.·Kung, K.·Chen, C.
Taipei Medical University/Shuang Ho Hospital
Taipei, TAIWAN.

Purpose
Spinal extradural arteriovenous fistulas (AVFs) are rare conditions. They are characterized by the presence of an arteriovenous communication, localized to the paraspinal soft tissues and the epidural venous plexus. Rangel-Castilla et al divided spinal extradural AVFs into three types based on venous drainage pattern and clinical presentation. In Type A spinal extradural AVFs, arteriovenous shunting occurs in the epidural space and these types have an intradural draining vein causing venous hypertension and spinal cord edema with associated myelopathy or cauda equina syndrome. Type B1 malformations are confined to the epidural space with no intradural draining vein, causing compression of the spinal cord and/or nerve roots with myelopathy and/or radiculopathy. Type B2 malformations also are confined to the epidural space with no intradural draining vein and no mass effect, and are asymptomatic. The author aims to introduce these rare conditions with case demonstration.
Approach/Methods
The author will exhibit four cases of extradural AVFs to demonstrate the spectrum of the disease. Clinical findings, diagnostic evaluation, treatment and outcome are discussed.
Findings/Discussion
Two cases of type A spinal extradural AVFs have extradural fistulous locations (both at L3 level) and large epidural venous lakes with intradural venous drainage. They presented with progressive myelopathy. Transarterial embolization (TAE) with N-butyl cyanoacrylate (NBCA) was performed to occlude the fistula and the venous lake in both cases successfully. Regression of cord edema was noted and the symptoms were relieved in one patient and improved in another. The third case presents with cervical radiculomyelopathy. Angiography revealed a type B1 extradural AVF at T12 level with epidural venous drainage but without intradural venous drainage. Transarterial embolization with NBCA was performed to occlude the fistula successfully. The symptoms completely resolved. The fourth case was an incidental finding. A type B2 spinal extradural AVFs at cervical level was noted without intradural venous drainage or mass effect on surround tissue. No treatment was needed.
Summary/Conclusion
Spinal extradural AVFs are rare malformations which differ from dural AV fistulae in many ways. Careful differentiation and evaluation with selective spinal angiography was important before the treatment to be performed.

KEYWORDS: Spinal arteriovenous malformation

EdE-90

Spectrum of Neuroradiologic Findings in the Conus Medullaris and Filum Terminale: A Pictorial and Educational Review

Horsburgh, A.[1,2]·Antoun, N.[1]·Massoud, T. F.[1,3]
[1]Addenbrooke's Hospital, Cambridge, UNITED KINGDOM,
[2]Queen's Hospital, Romford, UNITED KINGDOM,
[3]University of Cambridge, Cambridge, UNITED KINGDOM.

Purpose
The term "conus" is derived from the Latin word for "cone", thus describing the morphologic shape of the spinal cord's caudal tip. However, the conus medullaris is not just a tapered continuation of the superior spinal cord segments. It represents a distinct entity within the spinal cord, with its own unique complex anatomical and physiologic features. The filum terminale, which often is considered as just a fibrous extension of the cord, recently has been shown to contain nerve bundles, which may play a functional role in some individuals. Lesions of the conus and filum terminale tend to present generically as back pain or cauda equina syndrome. Expedient MRI of the lumbar spine often is performed to image both these structures and to exclude a compressive lesion. However, there is a very wide range of clinical diseases that can affect this region. The breadth of lesions both common and uncommon, which can affect the conus, can often lead to controversies in clinical and radiologicl differential diagnosis. Management strategies differ substantially, depending on the type of lesion. In this region early diagnosis followed by timely medical or surgical treatment is favored to preserve neurologic functions. Thus it is important for neuroradiologists to be familiar with the spectrum of diseases in this region and their imaging manifestations.
Approach/Methods
We review the imaging findings in a wide spectrum of common and uncommon pathologic processes affecting the conus medullaris and filum terminale.
Findings/Discussion
We review the unique imaging anatomy of the conus medullaris and filum terminale, along with a pictorial review and discussion of the imaging findings in many of the conditions affecting this region. These include neoplastic lesions such as glial tumors (e.g., ependymoma, astrocytoma, glioblastoma and ganglioglioma), and nonglial tumors [e.g., schwannoma, neurofibroma, hemangioblastoma, primitive neuroectodermal tumor (PNET), lymphoma and primary CNS melanoma], and metastatic disease. We also consider non-neoplastic lesions including demyelinating lesions, granulomatous

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

diseases (e.g., tuberculoma and sarcoidosis), infections including bacterial infections (e.g., pyogenic abscess) as well as parasitic infections (e.g., schistosomiasis, sparganosis and cysticercosis). We will discuss vascular abnormalities (e.g., cavernoma, arteriovenous malformations, arteriovenous fistula and conus infarction) and look at congenital lesions (e.g., spinal dysraphism, lipoma, epidermoid, dermoid cysts, teratoma and childhood tight filum syndrome). Very rare pathologies reported in the literature (e.g., intramedullary enterogenous cysts, endometriosis of the cauda equina) also are displayed.
Summary/Conclusion
Management strategies for conus medullaris and filum terminale abnormalities vary substantially, depending on the abnormalities revealed on neuroimaging. This presentation will aid in differentiating the often confusing imaging appearances of lesions in this region.

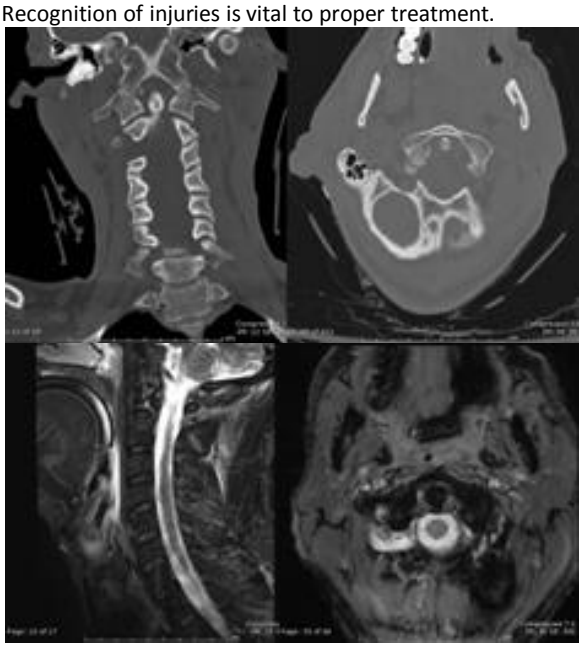
KEYWORDS: Conus, filum terminale

EdE-91

Occipital Condyle Fracture: An Under-Recognized Entity with Potentially Severe Sequelae: Review of Craniocervical Anatomy, Classification of Fracture and Ligamentous Injury, and Discussion of Imaging Techniques Aiding in Diagnosis

Myers, C.·Mehta, H.
Westchester Medical Center
Valhalla, NY.

Purpose
Occipital condyle fractures related to high-velocity head and neck trauma are rising in incidence with an increasing number of motor vehicle collisions. Evaluation of the skull base may be limited unless appropriate imaging technique is utilized, leading to missed diagnosis. This exhibit will discuss the relevant anatomy, classification of occipital condyle fractures, range of potential sequelae, how to focus on this region in clinical practice, as well as highlight current imaging techniques of the occipital condyle.
Approach/Methods
Multiple patients and associated imaging with CT and MRI of type I - III occipital condyle fractures as well as patients with ligamentous injury to the craniocervical junction are discussed. Anatomy and imaging of the skull base and craniocervical junction as well as occipital condyle fractures and associated ligamentous injury will be reviewed. Strategies and key regions of focus are discussed to increase the sensitivity and specificity of diagnosis for the interpreting radiologist.
Findings/Discussion
The Anderson and Montesano classification system describes type I - type III fractures, with increasing severity. Recognition and proper treatment is necessary to prevent spinal cord injury, particularly with type III fractures which often are associated with severe ligamentous damage and craniocervical instability. Recognition of injuries is vital to proper treatment.



Summary/Conclusion
Educational goals: 1) Understanding the anatomy of the craniocervical junction as well as classification system, treatment options, and outcomes for occipital condyle fractures and associated ligamentous injury. 2) Review of current imaging techniques with CT and MRI to maximize dectection of craniocervical junction injury. 3) Review of the radiologic approach to evaluation of the craniocervical junction to ensure appropriate detection of fractures and ligamentous injury.

KEYWORDS: Occipital bone, Fracture, ligaments, occipital condyle, skull base

Clinical Correlations between Imaging Findings in Spinal Hemorrhage and Clinical Outcomes in Trauma Patients

Meyer, M. A.·Shastri, R.·Khan, R.
University of Arizona
Tucson, AZ.

Purpose
The purpose of this exhibit is 1. Review the importance of magnetic susceptibility imaging within the spinal canal and discuss artifacts that may be a source of obscuration. 2. Explore prognostic implications of cord hemorrhage as described in the literature and explain why spinal cord hemorrhage in the setting of trauma has been demonstrated to be associated with fixed defects or poor prognosis.
Approach/Methods
A comprehensive literature review will be performed in order to provide accurate prognostic implications of cord

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

hemorrhage and its outcomes. A review of spinal anatomy, mechanisms of trauma and pictorial examples will ensue.
Findings/Discussion
We will review: 1. Illustrative review of anatomy of the spinal cord. 2. Neurologic deficits associated with spinal injury and key localization findings. 3. Mechanisms of traumatic spinal hemorrhage. 4. American spinal injury association grading system. 5. Key imaging findings on CT and MRI. 6. MRI and CT artifacts associated with spinal cord trauma. 7. Outcome scoring and prognostic benchmarks. 8. Case examples of cord hemorrhage associated with complete and incomplete neurologic impairment.
Summary/Conclusion
The viewer should gain an understanding of intrathecal hemorrhage as demonstrated on CT and MRI as well as understand the prognostic implication as it relates to associated neurologic deficits. By reviewing spinal cord anatomy as well as reviewing the American spinal injury association grading system, the viewer should have a better sense of the importance of identifying hemorrhage in these patients as well as the prognostic implications.

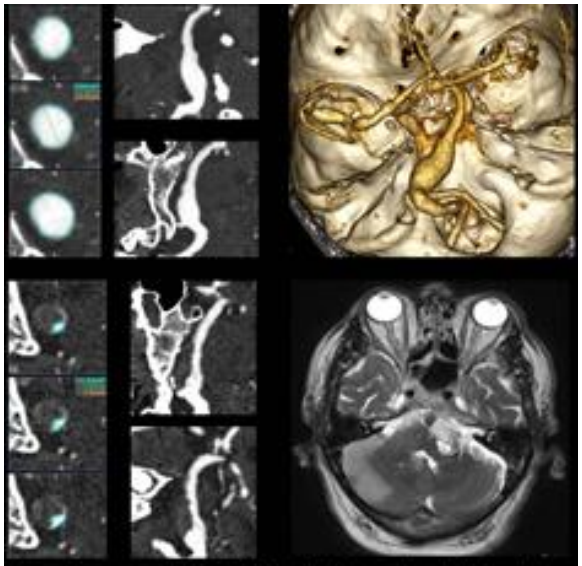
Multimodality Imaging of Vertebrobasilar Dolichoectasia: Clinical Presentations, Imaging Spectrum, and Imaging Optimization

Samim, M.·Goldstein, A.·Mahajan, A.·Schindler, J.·Johnson, M.
Yale University School of Medicine
New Haven, CT.

Purpose
The purpose of this exhibit is to: -Review the current diagnostic criteria of vertebrobasilar dolichoectasia (VBD) utilizing CT, MR, and angiography (DSA) and discuss their limitations. -Demonstrate different presentations of VBD. -Review how to optimize imaging protocols. -Review available treatment options.
Approach/Methods
We will present cases of patients, both asymptomatic and with discrete neurologic syndromes diagnosed with VBD based on radiologic criteria (ectasia, lateral displacement, and height). The following will be reviewed: -The current and available diagnostic criteria, including “Smoker criteria”. -The technique of high-resolution CT and MR pulse sequences and angiography tailored for evaluation of VBD and the imaging interpretation. -Multimodality imaging features of compressive and vascular complications. -How to recognize imaging points of critical importance for treatment planning. -How to optimize imaging modalities.
Findings/Discussion
Imaging VBD is challenging due to the effects of turbulent flow, calcifications and thrombus formation that have different appearances on each imaging modality. Correlation of CT, MRI and DSA may provide a better understanding of both anatomy and pathophysiology in this complex disorder. Vertebrobasilar dolichoectasia can have various clinical presentations. For example, abnormal arterial dilatation can cause mechanical stress upon the surrounding brain structures, resulting in compressive symptoms. Alternatively, neurovascular symptoms can result from transient ischemic attack (TIA), ischemic stroke, or hemorrhagic stroke. In this exhibit, we illustrate cases of patients presenting with compressive symptoms including hydrocephalus and cranial nerve palsies, for example vertigo, hearing loss, facial palsy, and trigeminal neuralgia. Additionally, cases with vascular symptoms including acute stroke and intracranial hemorrhage will be presented. Dolichoectatic vessels with larger diameters seem to be associated with a greater risk of stroke, while those that exhibit marked tortuosity and elongation may be associated with compressive symptoms. Imaging pitfalls related to thrombus, calcification and flow disturbances are demonstrated and strategies for imaging optimization discussed. For example, MR flow effects in VBD due to abnormal vessel configuration can be better differentiated from intraluminal thrombosis by protocol optimization.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



67 year old man presented with right sided facial and body weakness. Initial CT angiogram demonstrates basilar dolichoectasia with areas of narrowing and plaques within the vessel (Top). MR/MRA and repeat CTA within 1 day demonstrate extensive thrombus formation within the ventral aspect of the dolichoectatic basilar artery and acute infarct within the inferior half of the right cerebellum in an AICA/PICA territorial distribution (bottom).

Summary/Conclusion
Despite the lack of uniform diagnostic criteria, CT, multisequential MR, and angiography can be complimentary in the diagnosis of VBD and its compressive and vascular complications. By optimizing imaging protocols and recognizing imaging pitfalls, diagnostic accuracy can be improved. No standard treatment has been established to prevent the progression of the VBD; therefore, before the impact of any specific treatment can be addressed, a better understanding of the underlying pathophysiology of this disease is needed.

KEYWORDS: Basilar artery, Vertebral artery anomalies, dolichoectasia; stroke

Atypical and Symptomatic Developmental Venous Anomalies

Trimble, C. R.·Fortes, M.·Jindal, G.·Miller, T.·Gandhi, D.
University of Maryland School of Medicine
Baltimore, MD.

Purpose
Developmental venous anomalies (DVAs) are the most common of the cerebrovascular malformations with an incidence of up to 2.6% in the general population. These are believed to occur as a result of an embryologic event that leads to interruption in normal development of the venous system. The congenital absence of normal pial or subependymal veins leads to an “anomalous venous disposition,” in which the venous drainage patterns are reversed. While a vast majority of DVAs are incidental and benign, there is growing realization that a small fraction of these lesions may be symptomatic. In this case-based educational exhibit, we highlight the imaging features and potential complications of atypical DVAs.
Approach/Methods
Multimodality imaging of 45 cases of atypical DVAs was collected from the authors’ teaching collection and report database query.
Findings/Discussion
Developmental venous anomalies in our collection presented with varying clinical symptoms including headaches, seizures, focal neurologic deficits, and intracranial hemorrhage. The clinical sequelae of DVAs were likely related to associated regional venous hypertension. In this exhibit, we will highlight atypical features associated with these DVAs, including draining vein thrombosis, loco-regional venous hypertension and draining vein stenosis. Additionally we will describe cases of giant DVAs, arterialized DVAs, and DVAs associated with cortical dysplasia.
Summary/Conclusion
Enhancing, linear, venous radicles draining into a collector vein constitute the pathognomonic “medusa head appearance” of DVAs. While the majority of these lesions are asymptomatic, a small fraction of DVAs result in symptoms which may be attributed to atypical associated lesions, including cavernous malformations, arteriovenous malformations, cortical dysplasia or loco-regional venous hypertension. Familiarity with the imaging findings of atypical DVAs can help facilitate correct diagnosis of this condition.

eEdE-03

TRICKS of the Trade: Time-Resolved Contrast-Enhanced MRA and Accelerated Phase Contrast MRA Improve the Detection and Characterization of Carotid-Cavernous Fistulas

Hartman, L. A.·Turski, P.·Kennedy, T.·Hartman, M.·Aagaard-Kienitz, B.
University of Wisconsin Hospital and Clinics
Madison, WI.

Purpose
The purpose of this exhibit is to use an interactive case-based review to illustrate improved delineation of the cavernous sinus and venous drainage of carotid-cavernous fistulas (CCFs) using high-resolution 4D contrast-enhanced time-resolved MR angiography (MRA) and accelerated phase contrast (PC) MRA. Together these MRA techniques provide vascular images that detect arteriovenous (AV) shunting and demonstrate arterial supply and venous drainage patterns. In some cases CCFs may be relatively mild presenting only with orbital pain. In these instances, MRA evaluation is key in establishing the diagnosis of CCF.
Approach/Methods
We will present cases of CCFs using clinical photographs, clinical presentation, MRI/MRA findings and DSA vascular

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

anatomy. Current methods to improve spatial-temporal resolution of 4D contrast-enhanced MRA and PC MRA exams will be reviewed. Finally, a brief overview of treatment options for CCFs will be discussed including recent applications of focused radiation therapy.

Findings/Discussion

Carotid-cavernous fistula is an uncommon AV fistula that often initially presents as orbital pain. The diagnosis may be delayed as other causes of orbital pain are considered. Additional clinical symptoms include proptosis, chemosis, cranial neuropathies, decreased visual acuity and intracranial hemorrhage. Carotid-cavernous fistulas are characterized based on the Barrow classification. CT angiography and MRA can aid in depicting the arterial supply and venous drainage of CCFs. Findings associated with CCF on time-of-flight MRA include an enlarged cavernous sinus and a dilated superior ophthalmic vein with flow-related enhancement. With parallel imaging and 4D contrast-enhanced MRA (TRICKS and PC), a more definitive description of the venous drainage can be illustrated via early filling of the cavernous sinus and venous drainage pathway(s). These advanced MRA techniques can help identify the cortical venous drainage pattern (sphenoparietal sinus, cortical veins, petrosal veins, perimesencephalic veins), which places the patient at greater risk for intracranial hemorrhage and venous infarction, and often are treated more urgently. By demonstrating the venous drainage pathway(s) of a CCF, a preprocedure plan of treatment via endovascular route can be determined.

Figure 1A

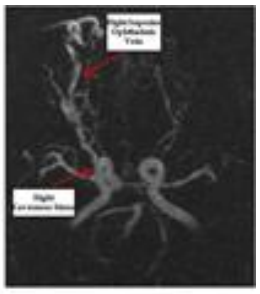

Figure 1B

Summary/Conclusion

We demonstrate representative cases of CCF based on DSA confirmed vascular pathophysiology. Advancements in temporal-spatial resolution of MRA allow important imaging features of CCF to be evaluated such as dominant arterial feeders, venous drainage pattern and morphologic changes in the orbit. We highlight the value of 4D MRA in the evaluation of patients presenting with orbital pain to establish the diagnosis early and avoid severe complications.

KEYWORDS: Cavernous carotid fistula, Dural arteriovenous fistula, magnetic resonance angiography

Imaging Appearance of Intracranial Dural AV Fistulas

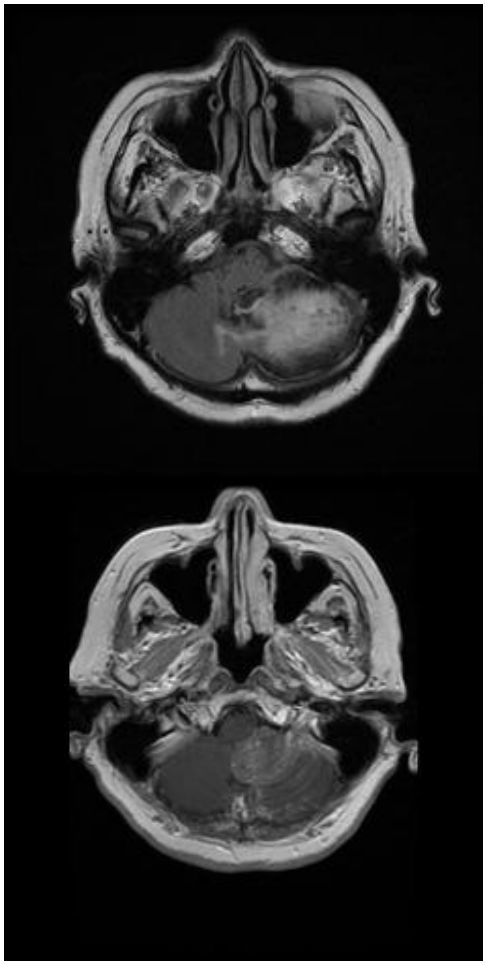
Fong, C.
Kaiser Permanente Los Angeles
Los Angeles, CA.

Purpose

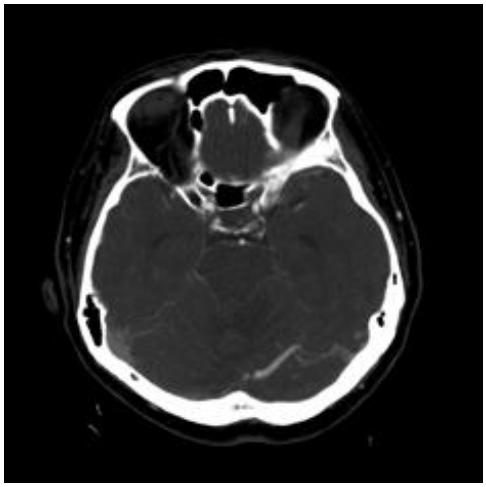
The purpose of this exhibit is to review the imaging findings of intracranial dural arteriovenous fistulas. Dural AV fistulas are notoriously difficult to diagnose or confirm with CT and MR.

Approach/Methods

This review will highlight findings that can be seen on cross-sectional imaging including draining or prominent veins, abnormal enhancement, edema due to venous congestion, calcification and prior hemorrhage. We also will review the different types of dural AV fistulas and the clinical connotations associated with them.



Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Summary/Conclusion
In summary, intracranial dural AV fistulas are difficult entities to diagnose, but awareness of this entity and its imaging findings can allow the astute radiologist to make this diagnosis.

KEYWORDS: Dural arteriovenous fistula, Arteriovenous fistulas

eEdE-05

Using Arterial Spin-Labeled MR Imaging to Identify Interictal Perfusion Abnormalities in Epilepsy

Raji, C. A.·Joe Qiao, J.·Wang, J.·Salamon, N.
University of California Los Angeles Medical Center
Los Angeles, CA.

Purpose
Epilepsy is a devastatingly chronic progressive neurologic disorder that affects one percent of the world population with an incidence of 70 per 100,000 per year. The number of new cases of pediatric epilepsy alone numbers approximately 300,000 per year. Despite the ability of MR imaging to identify structural lesions responsible for epilepsy cases, between 20-50% of patients with medically intractable epilepsy have no identifiable lesions on structural MR imaging. While brain SPECT offers important physiologic information in epilepsy diagnosis, it entails use of ionizing radiation that is less desirable particularly in the pediatric population. Perfusion imaging with arterial spin-labeled (ASL) MR imaging offers a powerful modality by which to noninvasively imaging and quantify cerebral perfusion without using ionizing radiation.
Approach/Methods
The purpose of our study is to illustrate how ASL can be clinically applied to identify perfusion defects in persons with epilepsy who have otherwise normal structural MR imaging. We possess a cohort of 361 individuals with epilepsy across the lifespan from infants to elderly aged 86. In this group, 32% (n = 117) had structural MR images that were interpreted as normal. The majority of this subgroup (n = 107) also received pulsed ASL MR imaging of the brain on a Siemens 3.0 T scanner during the interictal period. We will show examples of persons with epilepsy who have structurally normal MR scans such as in Figures 1-2.

Figure 1: One Year Old With Seizures

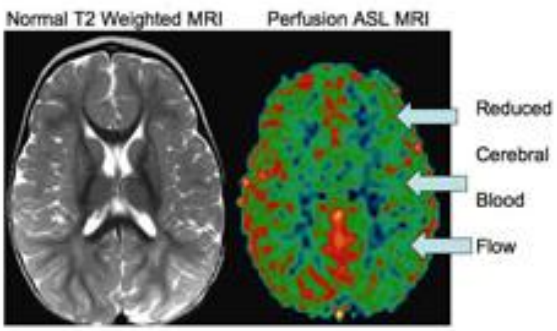


Figure 2: Three Year Old with New Onset Seizures

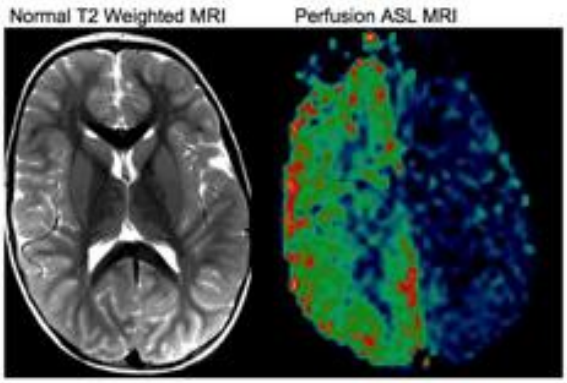

Findings/Discussion
We will summarize the imaging findings of this group with ASL, focusing on perfusion abnormalities. We hypothesize that ASL MR imaging in this epilepsy group with normal structural MR images will demonstrate hypoperfusion abnormalities in the interictal period.
Summary/Conclusion
This work will lend insight into the use of perfusion ASL MR imaging as a functional modality for improved diagnosis and classification of epilepsy.

KEYWORDS: Epilepsy, Arterial spin labeling

Cerebellar Atrophy: Can I Say Something other than "Clinical Correlation Advised"?

Pereira, L. P.·Sair, H.·Ying, S.
Johns Hopkins Hospital
Baltimore, MD.

Purpose
To review the magnetic resonance imaging (MRI) patterns of various pathologies that are associated with cerebellar

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

degeneration and to categorize these patterns according to anatomical involvement.
Approach/Methods
Cerebellar atrophy is a frequent finding in the typical neuroradiologic practice, and ataxia is a common presenting symptom. A wide variety of pathologies are related to regional or global reduction of cerebellar volume, which may or may not be accompanied by extracerebellar involvement. Here we present a radiologic approach to cerebellar intrinsic diseases associated with ataxia, with classic signs and less well recognized regional findings categorized according to anatomical involvement using conventional and advanced MRI.
Findings/Discussion
MR imaging frequently is performed in patients with ataxia. Neuroradiologists usually are well versed in ruling out structural lesions of the cerebellum, such as developmental abnormalities, vascular pathology, tumors, or trauma. However, in the remaining cases of cerebellar disease, it can be challenging to reach a more specific diagnosis, since patterns may overlap and have nonspecific appearances. In this review the authors classify conventional and advanced MRI findings according to the presence or absence of involvement in four major regions: 1) cerebellar cortex, 2) deep cerebellar nuclei and corpus medullare, 3) brain stem and cerebellar peduncles, and 4) other lesions outside the posterior fossa. Common pathologies that predominantly involve the cortical area include spinocerebellar ataxia (SCA) types 1 and 6, Friedreich ataxia (FA), Fragile X-Associated Tremor/Ataxia syndrome (FXTAS), the Autosomal Recessive Spastic Ataxia of Charlevoix-Saguenay (ARSACS), Neuropathy, Ataxia, and Retinitis Pigmentosa (NARP) syndrome, Cockayne syndrome, as well as paraneoplastic, alcohol, drug and gluten cerebellar damage. These pathologies can be subdivided further into regional patterns of involvement. Pathologies with prominent involvement of the deep cerebellar nuclei include FA, FXTAS and cerebrotendinous xanthomatosis (CTX). Pathologies with brain stem and/or cerebellar peduncle involvement are represented by multisystem atrophy, cerebellar type (MSA-c), SCA type 1 and 2, ARSACS and FXTAS. Pathologies that also demonstrate prominent CNS involvement outside of the posterior fossa include SCA type 3, MSA Parkinson type (MSA-p), NARP, ARSACS, Cockayne syndrome and ARSACS. We present a comprehensive classification schema for conventional and advanced MR findings, with brief clinical and imaging descriptions for each pathology.
Summary/Conclusion
Cerebellar atrophy is a diagnostic imaging challenge. Classification of imaging signs and predominant areas of involvement for the most frequent pathologies can be helpful in diagnostic evaluation and interpretation of conventional and advanced MRI.

KEYWORDS: Cerebellum, Degenerative, atrophy

eEdE-07

Basal Ganglia and Neurodegenerative Disorders

Bangiyev, L.[1]·Roudenko, A.[1]·Paydar, A.[1]·Milla, S.[1]·Naidich, T. P.[2]·Fatterpekar, G. M.[1]
[1]New York University Langone Medical Center, New York, NY, [2]Mount Sinai Medical Center, New York, NY.

Purpose
The purpose of this exhibit is to: 1. Discussing the anatomy and physiology of the basal ganglia. 2. Display the different “neurodegenerative" disease conditions involving the basal ganglia. 3. Providing imaging algorithms based on the age of the patient, location of the lesion in the basal ganglia, its morphologic appearance, and involvement of the other structures of the brain to help narrow the differential diagnosis.
Approach/Methods
Utilizing high-resolution T1-weighted images, T2-weighted images, and intermediate-weighted sequences and relevant graphic illustrations we will discuss in exquisite detail the anatomy and physiology of the basal ganglia. Normal and abnormal iron deposition will be discussed. Select CT and MR images will be used to display the different disease conditions involving the basal ganglia. Disease processes will be characterized into: - Deposition disorders: Wilson Disease, Hyperalimentation therapy (manganese), Pantothenate-kinase associated neurodegeneration (PKAN), Infantile Neuroaxonal Dystrophy, Parathyroid disorders and Fahr’s syndrome. - Toxic and Metobolic disorders: Kernicterus, Leigh syndrome, Hepatic encephalopathy, Carbon monoxide poisoning and Diabetic Striatopathy. - Infectious Diseases: TORCH, Creutzfeldt-Jacob disease, Cyptococcosis, and AIDS. - Movement disorders: Huntington Disease, Parkinson disease, and Parkinson-plus syndromes including Multiple System Atrophy. - Ischemic encephalopathy. - Traumatic Brain injury: Abnormal iron deposition.
Findings/Discussion
Lesions will first be distinguished based on their localization to the caudate nucleus, globus pallidus, putamen, subthalamic nucleus, and/or substantia nigra. Further differentiation will be made based on imaging characteristics, including density on CT as well as signal intensity on T1-weighted, T2-weighted/FLAIR, diffusion-weighted imaging, susceptibility-weighted and postcontrast sequences. In addition, involvement of other parts of the brain, such as the surrounding white matter structures, thalamus, cortex, cerebellum, and brainstem, also will be taken into account.
Summary/Conclusion
By utilizing a methodical approach we aim to provide the neuroradiologist an in-depth understanding of the anatomy and physiology of the basal ganglia. The information so gained along with a display of plethora of cases will assist in interpretation of and narrow the differential diagnoses for basal ganglia lesions based on

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

their location, laterality, extent of disease, imaging characteristics on MR and CT, as well as presence of other abnormalities outside of the basal ganglia.

KEYWORDS: Basal ganglia, Neurodegenerative

eEdE-08

Multimodality Imaging of Degenerative Brain Diseases: Moving Beyond Degenerative Dementias with Conventional Imaging and Nuclear Medicine

Verdoorn, J. T.·Hunt, C. H.
Mayo Clinic
Rochester, MN.

Purpose
The purpose of the exhibit is to: 1) Review the common nuclear medicine studies used to image degenerative CNS diseases with an emphasis on new imaging techniques for atypical degenerative brain disease; 2) Correlate the findings of the nuclear medicine studies with those seen on MRI and at pathology; 3) Discuss the potential role of quantitation in increasing specificity for the diagnosis with FDG and amyloid imaging PET/CT.
Approach/Methods
After a brief review of the nuclear medicine options for imaging degenerative CNS disease, a series of patients will be presented to demonstrate the added value of these studies in evaluation of degenerative CNS disease, including Parkinsonism, motor neuron disease, and autoimmune processes. This series also will include cases which demonstrate the potential limitations of nuclear medicine with examples of how false positive and false negative studies can be obtained. All studies will be correlated with conventional imaging (CT, MRI) as well as pathologic findings.
Findings/Discussion
Nuclear medicine can be a powerful tool in the evaluation of degenerative CNS disease and provide important diagnostic and prognostic information. While its usefulness in documenting degenerative dementias such as Alzheimer disease, frontotemporal dementia, and Lewy body disease has been well document, nuclear medicine also can provide powerful insight into other degenerative CNS diseases such as Parkinsonism, motor neuron disease, autoimmune disorders, and atypical degenerative dementias such as corticobasilar degeneration. The addition of automated quantitation can increase the specificity of the findings as well.
Summary/Conclusion
Nuclear medicine can provided significant added value to the evaluation of degenerative CNS disease. The combination of nuclear medicine including PET/CT and scintigraphy and conventional imaging (CT and MRI) can improve diagnostic and prognostic accuracy.

KEYWORDS: PET/CT, Degenerative

Imaging Differential Diagnosis of Conditions Other than Alzheimer Disease Presenting with Dementia

Patro, S. N.·Glikstein, R.·Chakraborty, S.
The Ottawa Hospital
Ottawa, ON, CANADA.

Purpose
The aim of this educational exhibit is: 1. To present various intra and extraaxial pathologic brain lesions we encountered in the workup of patients with dementia. 2. To discuss the different pathologies and their imaging features associated with dementia.
Approach/Methods
Twenty consecutive patients who underwent CT and MRI as part of the evaluation of dementia were reviewed in our hospital from November 2009 to November 2012.
Findings/Discussion
In this educational pictorial essay we are reviewing two patients with central pontine myelinolysis, two patients with multisystem atrophy-cerebellar variant, one patient with progressive supranuclear palsy, one patient with Creutzfeldt-Jakob disease, one patient with acute methanol toxicity, one patient with HIV encephalopathy, one patient with severe microangiopathic disease, two patients with CADASIL, one patient with Sjogren's syndrome, one patient with severe anoxic brain injury, one patient with bilateral chronic subdural hemorrhage, one patient with meningioma, one patient with olivoponto cerebellar atrophy and four patients with normal pressure hydrocephalus who presented with dementia. Dementia by definition is a gradual and progressive decline of cognition caused by various diseases of the brain. The global prevalence of dementia is estimated to be 24 million and likely to be double in the next 20 years. Alzheimer disease is the most common primary neurodegenerative disease. The less common causes are fronto-temporal dementia, diffuse lewy body disease, cerebrovascular disease, atypical Parkinsonism, CJD, HIV-related encephalopathy. It is also important to be aware of other treatable conditions like tumor, subdural hemorrhage and normal pressure hydrocephalus (NPH) which can produce features like dementia due to mass effect over the brain. Imaging is a part of the routine workup for all patients presenting with dementia. CT is the preliminary investigation to rule out treatable conditions. MR imaging with inherent high soft tissue resolutions helps in differentiating various types of dementia.
Summary/Conclusion
It is important to consider various etiologies in the workup of a patient with dementia. Imaging has now become a standard part of the diagnostic process in evaluating dementia.

KEYWORDS: MR imaging brain, Creutzfeldt-Jakob disease, hydrocephalus, HIV

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eEdE-10

"Change in Mental Status": Decoding Neuroimaging Clues for Systemic Processes of Excess and Deficiency

Liu, R.·Li, J.
Albert Einstein Medical Center
Philadelphia, PA.

Purpose
"Change in mental status" is perhaps the most commonly encountered indication for neuroimaging in a hospital setting for an increasingly complex group of conditions, which are often difficult to diagnosis clinically as they do not contribute to any focal neurologic signs and symptoms. Many of these conditions are due to systemic excesses or deficiencies in metabolites or in their regulation and have characteristic imaging findings. The ability to recognize and alert clinicians of these conditions can guide them to the proper diagnostic and laboratory examinations and lead to early, appropriate treatment. This educational exhibit outlines some of these conditions and highlights their characteristic imaging findings.
Approach/Methods
A search of the authors' teaching files and our PACS imaging archive was performed to identify potential patients with MR imaging of the following conditions: metabolic diseases of childhood, alcohol-related encephalopathy, vitamin deficiencies, toxic/metabolic diseases, hypertension/PRES, medication-induced encephalopathy, hypoxic/ischemic encephalopathy, and hypoglycemia. Images then were reviewed by authors to identify characteristic imaging features of these conditions. These then were displayed in an educational format via a PowerPoint presentation.
Findings/Discussion
Several of the systemic, inherited metabolic disorders of excess toxic metabolite accumulation are discussed including X-linked adrenoleukodystrophy, metachromatic leukodystrophy, and Canavan disease. In addition, excess accumulation of minerals leading to demyelination are discussed in the setting of alcoholism with examples of acute and chronic alcoholic encephalopathy as well as Marchiafava-Bignami disease. Cocaine abuse, methanol poisoning, and carbon monoxide poisoning are presented as examples of toxic metabolite accumulation. Methotrexate, tacrolimus, and metronidazole are displayed as examples of iatrogenic toxic effects. For the systemic deficiency disorders, we show characteristic imaging findings of thiamine and B12 vitamin deficiencies as well as those characteristic imaging findings present from lack of auto-regulation of blood pressure in posterior reversible encephalopathy syndrome. A lack of essential metabolites such as oxygen and glucose are demonstrated with acute hypoxic-ischemic injury, sub-acute hypoxic-ischemic encephalopathy, and hypoglycemia.
Summary/Conclusion
With prompt recognition of characteristic imaging findings in a variety of toxic and metabolic conditions, we can better serve our clinical colleagues by alerting them to the possibility of these diagnoses, guiding them to the proper laboratory examinations, and promoting early treatment as well as better patient outcome.

KEYWORDS: Encephalopathy, Metabolic

eEdE-11

Improved Detection of Cortical Malformations Using Curvilinear Reformatting of 3D Volumetric MR Imaging of the Cerebral Cortex in Combination with Diffusion Tensor Imaging

Campeau, N.·Patton, A.
Mayo Clinic
Rochester, MN.

Purpose
To illustrate the merits of using a 3D curvilinear reformatting postprocessing algorithm in combination with diffusion tensor imaging (DTI) for improved assessment of epileptogenic cortical malformations.
Approach/Methods
Three-dimensional (3D) volumetric T1-weighted data sets obtained from magnetic resonance imaging (MRI) studies performed for evaluation of individuals with epilepsy were postprocessed manually on a computer workstation using a 3D curvilinear reformatting algorithm to produce a flattened 2 dimensional rendition of the cortex of the entire brain. Reformatted images of the brain were obtained to depict the cortical surface, and serial reformatted curvilinear planes at varying depths/thickness from the cortical surface. All suspicious areas were correlated with diffusion tensor imaging (FA maps, tractography) when available.
Findings/Discussion
Pathology identified and processed with these techniques included focal cortical dysplasia, lissencephaly, pachygyria, polymicrogyria, and schizencephaly. The location of the pathology and extent of cortical involvement was improved with curved reformatting algorithm. Anatomical landmarks and their relationship to the location of abnormalities are determined more precisely with curved reformatting. Improved comparison of contralateral anatomy allows for more confident determination of subtle abnormalities. The specificity of imaging abnormalities seen with curvilinear reformatting is improved with use of DTI.
Summary/Conclusion
Curvilinear reformatting combined with DTI not only allows improved delineation of cortical malformations, but assists in identification of normal anatomical landmarks. These techniques provide an efficient and concise visual representation of pathology, useful for conveying imaging findings to referring clinicians for surgical planning and optimize the extent of pathologic resection.

KEYWORDS: Cortical malformation, 3D visualization

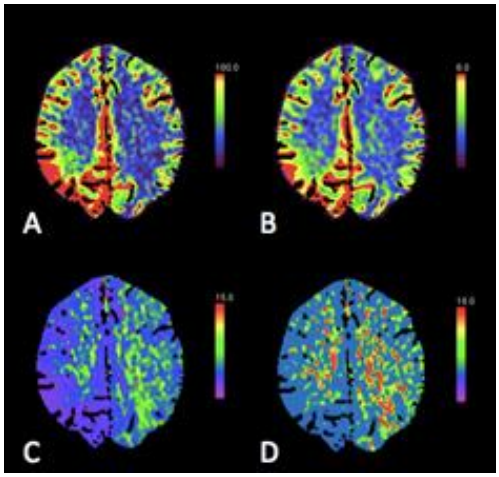
Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eEdE-12

Spectrum of CT Perfusion Findings in the Post-Ictal State

Boyer, A. C.·Spear, D.·Wilson, B.·Gupta, G.·Kramer, J.·Bakalis, C.·Wilseck, J.
Oakland University William Beaumont School of Medicine
Royal Oak, MI.

Purpose
Diagnosing transient neurologic deficits following seizure compared to deficits due to cerebral ischemia can be difficult in the acute setting. CT perfusion (CTP) imaging commonly is used in the setting of suspected acute cerebral ischemia. During a seizure, cerebral perfusion initially increases in affected regions, which reverses to hypoperfusion in the post-ictal state. Other perfusion abnormalities including a state of mixed hypoperfusion and hyperperfusion as well as isolated focal hyperperfusion also have been reported in the post-ictal state. The purpose of this educational exhibit is to present the spectrum of CTP imaging findings seen in the post-ictal state and discuss useful tips to differentiate post-ictal perfusion abnormalities from acute cerebral ischemia.
Approach/Methods
The basics of CTP will be discussed briefly. Typical alterations in seizure-related cerebral perfusion will be reviewed followed by a pictorial review of the spectrum of CTP findings in the post-ictal state. Imaging examples provided were generated from a review of 425 consecutive patients who underwent CTP for acute stroke-like neurologic symptoms at our institution over a 17-month period. These patterns of abnormal perfusion will be compared to a typical example of hypoperfusion due to cerebral ischemia. Finally, key factors that can be used to differentiate seizure from cerebral ischemia on CTP will be reviewed.
Findings/Discussion
CT perfusion imaging abnormalities are common following seizure. The most common CTP pattern seen in the post-ictal state is hypoperfusion with prolonged mean transit time (MTT) and time to drain (TTD) with decreased cerebral blood volume (CBV) and cerebral blood flow (CBF). Other patterns include isolated hyperperfusion with abnormally decreased MTT and TTD and increased CBV and CBF as well as a mixed pattern consisting of areas of hyperperfusion and areas of hypoperfusion. In cases of hypoperfusion, defects of CBF and CBV are matched. Post-ictal perfusion abnormalties can be seen in a holo-hemispheric, multi-lobar, or cortical ribbon pattern. The basal ganglia typically are spared while involvement of the thalamus is common.



Summary/Conclusion
Post-ictal cerebral perfusion abnormalities can present as a spectrum of findings on CTP imaging. Matched perfusion abnormalities occurring in a distribution not classic for a vascular territory without an associated abnormality on CT angiography should raise the possibility of seizure as the cause of a patient's neurologic deficit.

KEYWORDS: CT perfusion, Seizure

eEdE-13

Perioperative and Postoperative Surgical Epilepsy Imaging: A Pictorial Essay

Venkatesh, R. M.·Hasso, A. N.·Hsu, F. P. K.·Lin, J. J.·Handwerker, J.
University of California Irvine Medical Center
Orange, CA.

Purpose
Medically intractable epilepsy is a challenging problem that often requires a multidisciplinary surgical approach involving neurologists, neurosurgeons, and neuroradiologists. A plethora of surgical techniques, divided into general categories of resective and disconnective procedures, are available to address this issue, each with unique perioperative and postoperative imaging features. Given the complexity of the cases, the increasing number of surgical epilepsy patients, as well as the confounding imaging features involving multiple modalities, neuroradiologists must become increasingly familiar with perioperative and postoperative imaging features.
Approach/Methods
Drawing on the approach of a large epilepsy center, imaging examples of lobectomy, hemispherectomy, corpus callosotomy, multiple subpial transection, and vagal nerve stimulator patients will be demonstrated. Multiple imaging modalities including 3D reconstructions, fusion of images for intraoperative guidance, PET/CT, fMRI and DTI as well as conventional CT and MRI all play important roles in the evaluation of the surgical epilepsy patient. Intraoperative

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

images and detailed anatomical depictions that can help aid in understanding the characteristic radiologic appearances also will be shown. Numerous implantable devices are in use, and knowing the different types and their radiologic appearances is important for the neuroradiologist functioning as part of a multidisciplinary team.
Findings/Discussion
New techniques in imaging including 3D reconstruction and image coregistration for intraoperative guidance are allowing for a more thorough assessment and evaluation of the patient undergoing epilepsy surgery. Familiarity with these types of images is important to the future of epilepsy management. MR imaging findings of postsurgical patients should not be confused for other similar appearing entities and well known mimics. While difficult to interpret, imaging confounded by artifact from implantable devices still can provide valuable information. Lastly, examples of the common and uncommon complications from epilepsy surgery will be shown, such as the characteristic appearance of hemorrhage from subdural grid electrode placement for electrocorticography.
Summary/Conclusion
Given the increase in epilepsy surgery, neuroradiologists need to familiarize themselves with perioperative and postoperative imaging appearances of surgical epilepsy patients, especially in the setting of newer tools such as 3D imaging. As part of a multidisciplinary team, the neuroradiologist also should be familiar with common implantable devices. Anatomical drawings and intraoperative pictures correlating with radiologic findings can help with understanding the imaging appearances in epilepsy surgical patients.

KEYWORDS: Epilepsy, 3D imaging, postoperative findings

Reversible Focal T2 Hypointensity in Seizures Associated with Nonketotic Hyperglycemia

Lee, E.[1]·Jeong, B.[1]·Kim, K.[1]
[1]Dongguk University Ilsan Hospital, Goyang-City, KOREA, REPUBLIC OF, [2]Dongguk University Ilsan Hospital, Goyang-City, KOREA, REPUBLIC OF.

Purpose
Hyperglycemia rarely may be seen with seizures. Hyperglycemia may reduce seizure threshold because of the increase in gamma-aminobutyric acid metabolism and may trigger epileptic discharges. We describe MRI abnormalities in five patients with nonketotic hyperglycemia (NKH) and seizures, and also attempt to characterize the pathogenesis of this unusual finding.
Approach/Methods
We retrospectively evaluated clinical and radiologic abnormalities in five patients with NKH.
Findings/Discussion
All patients presented with seizures and long-standing diabetes mellitus. The MRI abnormalities observed acutely were focal subcortical hypointensities on T2-WI and FLAIR imaging in all patients with overlying cortical gyral hyperintensities in three patients. Focal overlying cortical or leptomeningeal enhancement on contrast-enhanced T1-weighted imaging or CE-FLAIR imaging, was observed in all patients. Diffusion-weighted imaging showed mild restricted diffusion in three patients with cortical gyral T2 hyperintensities. On clinical recovery, the subcortical T2 hypointensity and overlying cortical hyperintensities reversed in all patients.
Summary/Conclusion
Patients with seizures in NKH may have transient MRI abnormalities that are characterized by subcortical T2 hypointensity with overlying cortical or leptomeningeal enhancement in addition to cortical T2 hyperintensity. Recognition of this radiologic abnormality in NKH is important in restricting unwarranted investigations and to institute early therapy.

KEYWORDS: Diabetes, Seizure, MR imaging

Holy Grails of Epilepsy Imaging: The "Nonlesional" Patient, Multifocal and Extratemporal Epilepsy

Kim, P. E.[1]·Hazany, S.[2]·Liu, C. Y.[1]·Heck, C.[1]·Millett, D.[2]·Lerner, A.[1]·Rajamohan, A.[1]·Shiroishi, M.[1]·Go, J. L.[1]·Boyko, O.[1]·Henderson, R.[1]·Law, M.[1]
[1]University of Southern California Keck School of Medicine, Los Angeles, CA, [2]Rancho Los Amigos National Rehab Center, University of Southern California Keck School of Medicine, Los Angeles, CA.

Purpose
Epilepsy diagnosis and treatment is one of the most complex endeavors in the field of neuromedicine; thus, the role of neuroimaging in epilepsy often is poorly understood, even by neuroradiologists, unless one is intimately associated with a robust epilepsy surgical practice. The purpose of this educational exhibit is to familiarize the neuroradiologist with the role of imaging in the evaluation of the epilepsy patient, particularly those being considered for resective surgery, and to describe the advanced imaging strategies that must be employed for those patients with “normal” or nonlocalizing imaging studies and electrographically multifocal or extratemporal epilepsy.
Approach/Methods
Utilizing the experience of the University of Southern California Keck Medical Center Comprehensive Epilepsy Program, some of the most difficult diagnostic/therapeutic dilemmas, most often “nonlesional” or extratemporal epilepsy cases, were selected to illustrate the role of neuroimaging in such evaluations. The complex integration of advanced multimodality imaging, including PET-MRI coregistration, SISCOM, and 3D neuronavigation, with

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

clinical Video-EEG correlation and operative Phase II EEG guidance is discussed.
Findings/Discussion
A significant proportion of epilepsy cases are nonlocalizing with conventional neuroimaging, and commonly multifocal or extratemporal in origin. These cases make epilepsy diagnosis and treatment an extremely complex and challenging endeavor, stemming largely from current limitations of methodologies that can be used to assess and localize brain function. Additionally, resective surgery is potentially curative, but is a high-stakes endeavor that requires a high degree of confidence in data derived from a battery of diagnostic evaluations. Neuroimaging maintains a critical role in this assessment and is integrated somewhat differently into the complex epilepsy evaluation matrix compared to imaging evaluation of other neuropathologies because interpretation is highly dependent on clinical and electrographic correlation. This ultimately has important implications for neuroimaging interpretation and utilization.
Summary/Conclusion
Imaging in difficult epilepsy cases is a challenging undertaking with several unique elements relative to other neuroradiologic pursuits. We illustrate the most diagnostically challenging epilepsy cases to describe the strategic role of neuroimaging within the larger matrix of epilepsy diagnosis and treatment.

KEYWORDS: Multimodality imaging, MR imaging brain, SISCOM

The Hippocampus: A Review of the Imaging Characteristics that Differentiates the Pathology Affecting this Unique Component of the Limbic System

Elgethun, M. T.·Spearman, M. P.·Fukui, M. B.
Allegheny General Hospital
Pittsburgh, PA.

Purpose
The hippocampus is a component of the limbic system that can be affected by certain disorders due to its unique attributes. We will present an educational exhibit reviewing the unique anatomy of the hippocampus including its arterial supply, as well as reviewing disorders that can affect the hippocampus including mesial temporal sclerosis, infarction, infection, dementia disorders, seizure disorders and malignancy.
Approach/Methods
The education exhibit will review the anatomy and arterial supply of the hippocampus and its unique role as a component of the limbic system. The CT and MR imaging characteristic of the different pathologies will be presented in an interactive case review format. The exhibit will emphasize the critical importance of understanding the hippocampus to form an accurate differential diagnosis taking into consideration the patient history and imaging characteristics.
Findings/Discussion
Based on its specific characteristics, the hippocampus is susceptible to unique pathology. The exhibit will discuss how the location, history and imaging characteristics of pathology affecting the hippocampus can help to determine the etiology. The exhibit will use an interactive case review format to illustrate how the patient history and imaging characteristics can help narrow the differential. In addition, the cases will provide examples of the importance of understanding the anatomy, arterial supply and function of the hippocampus in regards to its unique pathologic disorders as listed above.
Summary/Conclusion
This education exhibit has reviewed the unique structure, arterial supply of the hippocampus and its function as a component of the limbic system. The exhibit has demonstrated the imaging findings on CT and MR of the different pathologies arising in the hippocampus. This exhibit is designed to reinforce and review the hippocampus to emphasize the importance of understanding its intricacies resulting in its unique susceptibility to pathology.

KEYWORDS: Limbic system, Anatomy, hippocampus

Brain Mapping: How Much Do You Know?

Gupta, S.[1]·Klein, A.[1]·Bhalla, M.[2]·Carranza, V.[2]·Ulmer, J. L.[1]·Leighton, M.[1]·Maheshwari, M.[3]·Ceranske, A.[1]·Baruah, D.[1]
[1]Medical College of Wisconsin, Milwaukee, WI, [2]Medical College of Wisconsin Affiliated Hospitals, Milwaukee, WI, [3]Childrens Hospital, Medical College of Wisconsin, Milwaukee, WI.

Purpose
An interactive case-based electronic quiz utilizing preoperative functional MR imaging (fMRI) and diffusion tensor imaging (DTI) data obtained for localizing at-risk functional networks (language, motor, vision) prior to tumor resection.
Approach/Methods
CC-FA DTI maps for this review were obtained with a 1.5 T system (GE Medical Systems, Milwaukee, WI) by using a dual-refocused spin-echo technique, 3 mm slice thickness, 13 gradient-encoding directions, a b-value = 900, an NEX = 2, a TE = 70 ms, and a TR min = 11 s to acquire 40 contiguous slices with a 128 x 128 matrix and 240 mm field of view. Axial, coronal, and sagittal CC-FA maps are used in an interactive quiz. Bold fMRI data also were acquired with motor, speech/language, and vision paradigms. Knowledge of specific white matter tracts, functional cortical regions, structure/function relationships, and proposed clinical deficits are tested and reinforced using a multiple choice format.
Findings/Discussion

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Three separate brain-mapping cases are presented in the following sequence: clinical presentation, conventional CT and MR imaging, preoperative fMRI and DTI data, surgical correlation, and postoperative imaging. Multiple choice questions and point-and-click functionality are used to test the user's knowledge of relevant functional anatomy and concepts. Five questions per case have been created for a total of 15 questions. The user's correct answers are recorded, and a final tally is displayed at the conclusion of the quiz. Three summary slides at the end of the exhibit illustrate the important concepts.
Summary/Conclusion
The goal of this interactive electronic quiz is to teach and reinforce functional anatomical considerations in brain tumor patients prior to surgery. When used effectively, fMRI and DTI have a profound impact on the preservation of language, motor, and vision networks.

Demystifying Clinical Applications of Functional MR Imaging

Badve, C. A.·Vidal, L. L. M.·Blackham, K. A.·Sunshine, J. L.
University Hospitals Case Medical Center
Cleveland, OH.

Purpose
The purpose of this exhibit is to present the clinical application of functional MR imaging (fMRI) by describing the physiologic basis, reviewing the typical imaging acquisition and standard processing techniques, as well as illustrating day-to-day interpretation through clinical cases.
Approach/Methods
The viewer will first undergo a short self-evaluation to assess level of his/her current knowledge on fMRI. Subsequently, a succinct and relevant discussion on eloquent cortex anatomy, BOLD effect physiology and a typical fMRI imaging protocol will be presented. Then we will present an interactive session utilizing routine but exemplar clinical cases that display the primary and accessory motor cortex, speech generation and comprehension areas as well as the visual cortex within a variety of presurgical lesions and clinical scenarios. At the conclusion of the module, the viewer will be offered a second self-evaluation to assess newly acquired knowledge. The viewer also will be able to explore several hyperlinks, which will provide additional reading sources and fMRI trivia.
Findings/Discussion
Functional MRI is an elegant tool for assessing cortical activation and delineating eloquent cortex, based on the phenomenon of increased cortical activity leading to increase in oxyhemoglobin concentration. This in turn leads to small yet detectable signal changes on T2* images acquired during resting state as well as with different tasks that cause cortical activation. Intricate statistical postprocessing techniques allow quantitative comparison of signal between these states which then is utilized for radiologic interpretation. Functional MRI can identify the primary motor, visual and speech areas in the cortex in cooperative patients. This information permits the assessment of the spatial relationship between brain lesions and these critical areas. Current fMRI applications may include surgical and radiotherapy planning for brain tumors, arteriovenous malformations and epileptic foci resection. This noninvasive technique can enable greater margin of safety in surgical planning so as to minimize collateral damage during the surgery.
Summary/Conclusion
The authors present an interactive educational exhibit on the basic methods of fMRI acquisition, processing and interpretation that can be applied to a range of typical clinical scenarios. This exhibit, with the pre and postevaluations, will serve as an engaging self-learning exercise for the viewers. Residents and fellows will have an opportunity to familiarize themselves with this unique technique. Practicing neuroradiologists will reinforce their confidence on this topic with this refresher module.

KEYWORDS: fMRI, Motor cortex

eEdE-19

Nuclear Imaging for Neuroradiologists: PET-CT and Beyond

Go, M.[1]·Mukhi, S. V.[2]·Donohoe, K.[1]·Moonis, G.[1]
[1]Beth Israel Deaconess Medical Center, Boston, TX,
[2]Michael E DeBakey VA Medical Center, Houston, TX.

Purpose
To review established and emerging nuclear imaging studies that may be encountered by the practicing neuroradiologist and head and neck radiologist.
Approach/Methods
We will present illustrative nuclear imaging cases with cross-sectional correlation for the following entities: 1. Fluorodeoxyglucose (FDG) positron emission tomography (PET) for diagnosing Alzheimer disease; 2. Amyloid ligand imaging with PET for diagnosing Alzheimer disease; 3. FDG PET for differentiating radiation necrosis from recurrent brain tumors; 4. Thallium scan for differentiating radiation necrosis from recurrent brain tumors; 5. FDG PET for evaluating brain metastases; 6. FDG PET scan for differentiating lymphoma from toxoplasmosis; 7. I-123 MIBG for imaging neuroendocrine tumors; 8. In-111 pentetreotide scan for imaging neuroendocrine tumors; 9. I^{123} ioflupane for diagnosing Parkinson disease; 10. FDG PET for diagnosing mesial temporal sclerosis; 11. Tc-99m red blood cell (RBC) blood pool imaging for diagnosing calvarial hemangioma;12. Tc-99m Sestamibi for detection of parathyroid adenoma; 13. In-111 DTPA cisternography for diagnosing cerebrospinal fluid (CSF) leaks and 14. Tc-99m DTPA for confirming brain death.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Findings/Discussion
MR imaging (MRI) and CT are the most commonly used modalities for imaging the brain and head and neck. However, functional nuclear imaging is playing an increasingly important and expanding role for diagnosing certain lesions in the brain and head and neck. The most common nuclear study encountered by the neuroradiologist is FDG PET-CT for the evaluation of head and neck cancer; however, there are many other established and emerging scenarios where the use of nuclear imaging provides invaluable information that may not be obtained through conventional CT or MRI. We depict a wide range of nuclear imaging studies that the neuroradiologist may encounter, describe the indications, mechanisms of action, and expected imaging findings with cross-sectional correlation, where appropriate.
Summary/Conclusion
Our exhibit illustrates and elucidates a wide range of nuclear imaging examinations that may be encountered by the neuroradiologist or used as an adjunct when conventional CT or MRI does not or cannot provide a definitive diagnosis.

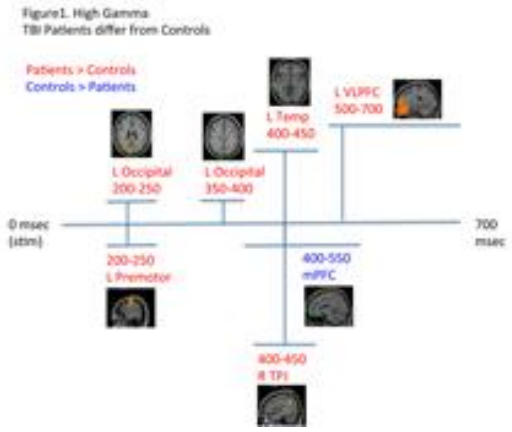
MEG Time-Frequency Activity during Attentional Conflict in Traumatic Brain Injury

Luks, T. L.·Dale, C. L.·Tarapore, P. E.·Cooper, S.·LaHue, S. C.·Findlay, A. M.·Lee, H. A.·Honma, S. M.·Mizuri, D.·Nagarajan, S.·Mukherjee, P.
University of California San Francisco
San Francisco, CA.

Purpose
Patients with traumatic brain injury (TBI) are known to have persistent cognitive deficits, particularly in attention and working memory functions. We used magnetoencephalography (MEG) to examine the millesecond timecourse of neural activity during a Stroop Attention Task in four frequency bands with a beamforming source localization.
Approach/Methods
Data were acquired from 19 adult patients with mild or moderate TBI and 13 healthy controls using a 275-channel whole-head biomagnetometer (CTF Systems, Vancouver, BC) and analyzed in the time-frequency domain using Nutmeg (bil.ucsf.edu/nutmeg). Activity at each voxel over time was calculated at four different time frequencies of interest (theta: 4-7 Hz, alpha:8-12, beta: 12-30 Hz, low gamma: 30-55 Hz, high gamma: 63-117 Hz). For each participant, activity in each voxel for incongruent versus congruent trials (i.e., Stroop Conflict-related activity) was calculated and submitted to within and between group analyses.
Findings/Discussion
Control subjects had significant conflict-related activity in prefrontal and temporal regions in all four frequency bands, including activity in Dorsolateral Prefrontal Cortex (DLPFC) and Anterior Cingulate Cortex (ACC), beginning as early as 50 msec post-stimulus and extending through our 700 msec window (the point at which motor responses begin to occur). In these regions with normal conflict-related activity (as defined by the control group), TBI patients had equivalent or reduced activity. However, TBI patients had extensive significantly increased activity in other frontal, temporal and occipital brain regions in each frequency band. High Gamma activity in right prefrontal cortex from 350-450 msec and right ACC from 350-400 msec was associated with neurocognitive conflict processing scores in TBI patients, and this activity in right prefrontal cortex also was associated with Extended Glascow Outcome Scale (GOSE) scores, a measure of clinical status.



Summary/Conclusion
These results suggest that during attentional conflict, TBI patients had reduced activity in prefrontal attention networks, but increased compensatory activity in other regions, and that these cognitive changes were associated with clinical status.

KEYWORDS: Traumatic brain injury, MEG, attentional conflict

eEdE-21

Imaging of Viral Infection and White Matter Disease: Differential Diagnoses and Imaging Pitfalls

Moritani, T.·Kirby, P.
University of Iowa Hospitals and Clinics
Iowa City, IA.

Purpose
To demonstrate CT and MRI findings of white matter disease with various viral infections. To illustrate the pathology and pathophysiology and discuss the differential diagnosis.
Approach/Methods
We reviewed CT and MRI findings including diffusion-

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

weighted imaging (DWI) in 46 patients with white matter involvement associated with viral infections. These cases are comprised of encephalitis/encephalopathy related to herpes simplex virus type 1 and 2, varicella zoster virus (VZV), Epstein-barr (EB) virus, cytomegalovirus, human herpes virus (HHV) type 6, human immunodeficiency virus (HIV), hepatitis virus, influenza virus, enterovirus, rotavirus, West Nile virus (WNV), progressive multifocal leukoencephalopathy (PML, JC virus), subacute sclerosing panencephalitis (SSPE, measles) and mild encephalitis/encephalopathy with a reversible splenial lesion (MERS). The diagnosis was based on antibody titers and MR imaging. Histopathology (biopsy or autopsy) was obtained in five patients.
Findings/Discussion
Herpes simplex encephalitis (HSE) is the most common cause of sporadic fatal encephalitis, accounting for 10-20% of encephalitic viral infections. Diffusion-weighted imaging was more sensitive than conventional MRI in detecting early changes of herpes encephalitis which is important for the treatment with acyclovir reducing the mortality. Pathologically, herpes encephalitis showed both cytotoxic and vasogenic edema associated with massive tissue necrosis and petechial or even confluent hemorrhage. The medial temporal lobes, inferior frontal lobes and insula commonly were involved. However, in infants and young children, the lesions tended to extend into frontoparietal lobes. In neonatal herpes simplex type 2 encephalitis, cerebral cortex and white matter were involved in a more global fashion. Human herpes virus-6-associated encephalitis has been recognized increasingly as a serious complication in immunocompromised patients. MR imaging often showed mesial temporal lobe involvement similar to HSE. However, ganciclovir and foscarnet are the treatment of choice. Multifocal cortical and white matter lesions were seen in VZV encephalitis and SSPE. Cytomegalovirus infection often involved periventricular white matter. Progressive multifocal leukoencephalopathy is characterized by demyelination, associated with oligodendrocytes infected with the JC virus. It usually is encountered in immunocompromised patients. West Nile virus develops meningoencephalitis. MR imaging showed mild hyperintense lesions on T2 and FLAIR in the basal ganglia, thalami, mesial temporal lobe, white matter, cerebellum, brain stem, especially the substantia nigra and medulla. Pathology demonstrated lymphocytic neutropholis perivascular lymphocytic cuffing, microglial nodules, spongiotic changes, and necrosis. White matter lesions in PML characteristically extended into the subcortical U-fibers. Cerebellar and brain stem involvements were common. The degree of lesion enhancement depended upon the patient's immunologic state. The pathologic hallmark of HIV encephalopathy/encephalitis is multinucleated giant cells in the white matter. MR imaging showed diffuse periventricular white matter lesions, but brain stem and basal ganglia also could be involved. Mild encephalitis/encephalopathy with a reversible splenial lesion secondary to viral infections (EB, influenza, rotavirus) also were demonstrated.
Summary/Conclusion
We demonstrate CT, MRI and DWI findings of viral encephalitis/encephalopathy with white matter involvement and various distributions. We discuss the differential diagnosis based on the characteristic distribution, and illustrate the underlying pathology and pathophysiology.

KEYWORDS: Encephalitis, Encephalopathy, viral

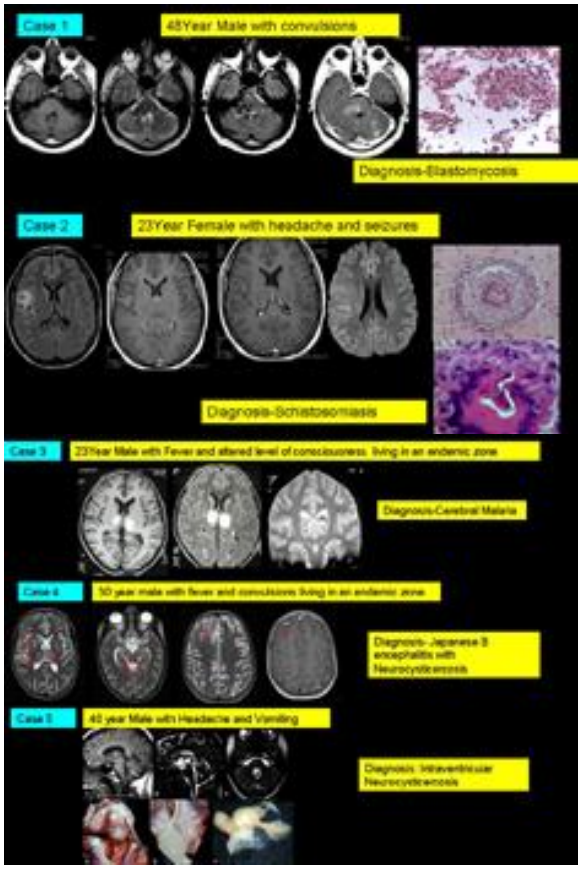
eEdE-22

Multidisciplinary Approach to Tropical and Subtropical Infectious Diseases: Imaging with Pathologic Correlation

Hanagandi, P. B.[1]·Goncalves, F. G.[2]·Amaral, L. F.[3]·Chong, J.[1]·Torres, C. I.[1]·Chankowsky, J.[1]·del Carpio, R.[1]
[1]Montreal General Hospital, McGill University, Montreal, QC, CANADA, [2]Radiologia Infinita - Brasilia Children's Hospital, Brasilia, BRAZIL, [3]Hospital da Beneficência Portuguesa de São Paulo & Hospital São José, São Paulo, BRAZIL.

Purpose
To highlight the diverse neuroimaging features of various endemic tropical and subtropical infectious diseases with serology and pathologic correlation.
Approach/Methods
We intend to describe the pathognomonic CT and MR imaging features of several tropical/subtropical CNS infections. We include a selection of both common and rare bacterial, granulomatous, viral, fungal and parasitic infections with interactive differential diagnosis.
Findings/Discussion
The spectrum of tropical/subtropical infections can present with a wide range of clinical symptoms ranging from fulminant to insidious onset, as well as chronic/progressive to relapsing/remitting course. Many of these diseases have pathognomonic imaging findings related to specific anatomical sites of CNS involvement. Others are less specific and require laboratory confirmation. Based on a high index of clinical suspicion, demographics and specific laboratory investigations one often can make an accurate diagnosis. This pictorial includes cases of tuberculosis, neurocysticercosis, toxoplasmosis, neurosyphilis, schistosomiasis, trypanosomiasis, hydatid disease, blastomycoses, cryptococcosis, amoebic encephalitis, poliomyelitis, Japanese encephalitis, cerebral Malaria, West Nile encephalitis, varicella, listeriosis and HIV differential diagnosis and brief interactive discussion.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Summary/Conclusion
In view of the increasing immigration to Western countries as well as the popularity of world travel, many of these diseases are now evolving from endemic to worldwide phenomena. The radiologist needs to be aware of patients background and familiarize one's self with both the characteristic and unusual imaging features of these diseases to avoid diagnostic delay and complications.

eEdE-23

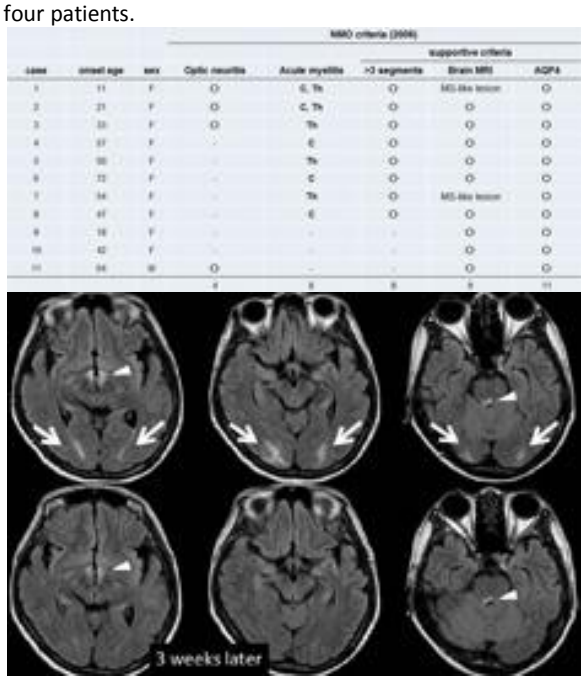
MR Imaging and Clinical Characteristics of Anti-Aquaporin4 Antibody Positive NMO or NMO Spectrum Disorders

Kurobe, Y.·Maeda, M.·Umino, M.·Sakuma, H.
Mie University School of Medicine
Tsu, JAPAN.

Purpose
The anti-aquaporin4 (AQP4) antibody has been incorporated into diagnostic criteria for neuromyelitis optica (NMO). Some anti-AQP4-positive patients who do not match the diagnostic criteria are termed as NMO spectrum disorders. This exhibit presents characteristic MR imaging findings and clinical findings of anti-aquaporin4 antibody positive NMO or NMO spectrum disorders.

Approach/Methods
We recruited 11 patients with anti-aquaporin4 antibody positive NMO or NMO spectrum disorders at our hospital, including three patients with definite NMO, five patients with myelitis, and one patient with optic neuritis. However, two patients had neither myelitis nor optic neuritis. MR imaging and clinical characteristics of those patients were evaluated retrospectively.

Findings/Discussion
A summary of clinical and MR imaging findings is shown in the Table. All eight patients with myelitis had typical contiguous spinal lesion over three or more vertebral segments. Contrast-enhanced MR imaging revealed definite enhancement in four patients. The enhancement pattern was identical to that of spinal sarcoidosis in two of the four. Brain lesions were detected in 10 patients. Four patients showed characteristic NMO lesion locations such as the dorsal brainstem or hypothalamus. Among the four, one patient showed posterior reversible encephalopathy syndrome in her clinical course (Figure). Four patients showed nonspecific lesions, but two patients showed periventricular ovoid lesions resembling those of multiple sclerosis. MR spectroscopy showed decreased NAA/Cho in four patients.



Summary/Conclusion
We will present typical and atypical MR imaging findings as well as clinical findings of anti-aquaporin4 antibody positive NMO or NMO spectrum disorders in light of the literature. This exhibit enhances knowledge related to anti-aquaporin4 antibody positive NMO or NMO spectrum disorders.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

KEYWORDS: MR imaging, Neuromyelitis optica, NMO spectrum disorders

eEdE-24

Neuroimaging of the Complications of Natalizumab Therapy in Multiple Sclerosis: A Pictorial Review

Honce, J. M.
University of Colorado
Aurora, CO.

Purpose
Natalizumab is an effective therapy for patients with multiple sclerosis (MS), and is being prescribed with increasing frequency, in some cases as a first line agent. With the increased utilization of natalizumab, complications associated with this therapy are seen more often in clinical practice. The primary complication of natalizumab therapy is the rare but devastating progressive multifocal leukoencephalopathy (PML). Fortunately, rapid drug withdrawal, usually by plasma exchange, has improved patient survival. Unfortunately, a new problem, PML associated immune reconstitution inflammatory syndrome (PML-IRIS), has emerged after drug withdrawal, and has a significant negative impact on patient outcomes. The IRIS phenomenon is not limited to PML treatment, and has been described recently in patients ceasing natalizumab therapy for other reasons (a phenomenon we term natalizumab rebound). The purpose of this exhibit is to discuss the MR imaging (MRI) features and clinical characteristics of natalizumab associated PML, PML-IRIS and natalizumab rebound, with emphasis on the early imaging features, allowing rapid diagnosis, treatment and/or modification of therapies to improve patient outcomes.
Approach/Methods
Using a case-based, interactive approach, cases of PML, PML-IRIS and natalizumab rebound that were diagnosed and/or treated at our institution are reviewed. The MRI features and clinical characteristics of natalizumab associated PML are detailed, focusing specifically on features of PML lesions very early in the disease when patients are asymptomatic or nearly asymptomatic, and before more classical PML lesions have developed. Imaging features that are predictive of earlier/more aggressive PML-IRIS are discussed, as are the MR findings of PML-IRIS itself. Finally the MRI features and clinical characteristics of natalizumab rebound are detailed, focusing on differentiating this phenomenon from conventional MS relapses.
Findings/Discussion
To limit the devastating impact of natalizumab associated PML and PML-IRIS it is crucial that neuroradiologists recognize their clinical and imaging spectrum, especially the earliest features of these disease processes. The shape, location and distribution of lesions, T1-weighted hypo or hyperintensity, microcyst/granular appearance on T2-weighted imaging, patterns of contrast enhancement, and hyperintensity on diffusion imaging are all key to making a confident, early diagnosis of PML and excluding differential considerations such as MS relapse, ADEM, or other infectious/inflammatory processes. Early contrast enhancement and widespread disease are associated with poorer patient outcomes, independent of delays in diagnosis, and predict earlier development/increased severity of PML-IRIS. Natalizumab rebound is an aggressive inflammatory response occurring months after drug cessation, and is characterized by an atypically high number of enhancing lesions in a widespread distribution, tending to occur at pre-existing T1 hypo intense lesions. Recognizing and differentiating natalizumab rebound from an MS relapse is critical as more aggressive therapies usually are needed.
Summary/Conclusion
After viewing this exhibit, the learner will: A - Recognize the clinical and imaging features of natalizumab associated PML, including features occurring early in the disease, when the patient is asymptomatic or near asymptomatic. B - Recognize the imaging features of PML-IRIS, and MR findings on initial imaging predictive of earlier/more aggressive PML-IRIS and poorer patient outcomes. C - Differentiate between conventional MS relapse and the aggressive inflammatory response of natalizumab rebound.

Spectrum of Drug-Induced Complications in the Brain: A Primer for the Radiologist

Rohatgi, S.[1,2]·Hsu, L.[1,2]
[1]Brigham and Women's Hospital, Boston, MA, [2]Harvard Medical School, Boston, MA.

Purpose
1. To illustrate via examples, the various imaging characteristics of drug-induced complications in the brain.
2. Clinical management and prognostic implications of imaging changes.
Approach/Methods
In this exhibit, we will demonstrate and discuss the various drug-induced imaging findings in the brain, which often present as diagnostic dilemmas due to their rarity and lack of clinical familiarity. Key pertinent differential diagnosis and management issues also are included.
Findings/Discussion
Drug-induced central nervous system (CNS) findings are varied and may not be familiar to practices that commonly do not interact with certain patient populations such as oncological specialties and their multiple drug treatment protocols. Often the cases are made even more challenging due to a lack of appropriate history or misleading presentation. As the patients often are followed up at different imaging centers it is important for the radiologist to be aware of some of these findings, to

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

provide better patient care especially in the outpatient settings. Central nervous system toxicity due to recreational drugs and alcohol are relatively common and well documented. Neuroimaging changes that are due to methotrexate, platinum derivatives, cyclosporin and metronidazole are less frequent. In the current era of molecular targeted therapy, especially in cancer patients with their many evolving treatment options, brain is at particular risk for side effects. Novel toxicities and new imaging appearances are seen in patients on antiangiogenic agents like bevacizumab (avastin), tyrosine kinase inhibitors, monoclonal antibodies like ipilimumab and natalizumab (Tysabri). Potential complications include hemorrhages, ischemic strokes, posterior reversible encephalopathy (PRES), hypophysitis and progressive multifocal leukoencephalopathy (PML). These drug-related sequelae vary from self limiting reversible manifestations to severe life-threatening conditions, thus early recognition is paramount so that appropriate therapy can be instituted promptly and misdiagnosis avoided.
Summary/Conclusion
We have reviewed the imaging spectrum of drug-induced complications in the brain using case-based examples. Awareness of these complications on imaging is important as it can improve outcomes by initiating the appropriate treatment as well as cessation of the offending drug. This exhibit is designed to provide a framework by which general and neuroradiologists may work in concert with clinicians to optimize patient care and treatment outcomes.

Virchow-Robin Spaces also Known as Perivascular Spaces: Why Should I Care?

Patel, T. Y.·Blackham, K. A.·Coffey, M. D.·Badve, C. A.·Vidal, L. L. M.·Javadi, P.
University Hospitals Case Medical Center
Cleveland, OH.

Purpose
The purpose of this Educational Exhibit is twofold: a) to demonstrate the anatomy and physiology of Virchow-Robin spaces also known as perivascular spaces; and b) to discuss common pathology affecting these intracranial spaces.
Approach/Methods
Users will be exposed to an image-based format to appreciate the anatomy and physiology of perivascular spaces. This will be followed subsequently by a case-based discussion on the most common pathology affecting these spaces as well as the mimics of dilated perivascular spaces. To consolidate the concepts learned, users will have the chance to go through a self-assessment module at the end of each section.
Findings/Discussion
Virchow-Robin spaces are pial-lined perivascular spaces filled with interstitial fluid that surround perforating intracranial blood vessels as they travel from the subarachnoid space through the brain parenchyma. They follow CSF intensity on all MR sequences. Based on their characteristic location within the brain, these spaces are subdivided into three different types. While they are normal structures in the brain and can be seen with increasing frequency and size with advanced age, it is important to distinguish them from pathologic mimics giving the appearance of apparently dilated perivascular spaces such as lacunar infarcts, neurocysticercosis, arachnoid cysts, and cystic neoplasms. Furthermore, there are several important disease entities that cause abnormal enhancement as well as true lesions of these otherwise normal appearing perivascular spaces. Classic examples include neoplasms such as glioblastoma and lymphoma, vasculitis including primary cerebral angiitis, infectious etiologies such as meningitis, and inflammatory conditions such as sarcoidosis and amyloidosis.
Summary/Conclusion
This educational exhibit will be helpful for the residents and fellows to appreciate the nuances of perivascular spaces. Additionally, it will serve as a quick review for the more experienced neuroradiologists.

KEYWORDS: Virchow-Robin space, Anatomy, pathology

eEdE-27

A Case of CLIPPERS: A Rare, Recently Described Inflammatory Brainstem Condition with a Review of the Differential Diagnosis

Tarabishy, B.·Aho, T. R.
Henry Ford Hospital
Detroit, MI.

Purpose
Chronic lymphocytic inflammation with pontine perivascular enhancement responsive to steroids (CLIPPERS) is a recently described autoinflammatory disease of predominantly the brainstem and cerebellum with distinct clinical, radiologic and pathologic features. To date, approximately 30 cases have been reported in the literature. We report a case of CLIPPERS at our institution with follow-up imaging and supplement it with a thorough differential diagnosis with illustrative cases.
Approach/Methods
A detailed history along with physical exam, laboratory findings and imaging findings for a case of CLIPPERS at our institution is presented. Findings from recently published literature also are reviewed and presented. Finally, a detailed differential diagnosis is reviewed accompanied by illustrative cases.
Findings/Discussion
Our patient illustrates the unique clinical and imaging findings of CLIPPERS including nonspecific laboratory findings and a characteristic "salt and pepper"

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

enhancement pattern on MRI with marked improvement after steroids. Review of the literature confirms these features as reliable indicators of CLIPPERS.
Summary/Conclusion
CLIPPERS is a newly described autoinflammatory disease of the brain with distinct and characteristic clinical, pathologic and imaging findings that should be included in the differential of interpreting physicians whenever the suggestive imaging findings are seen in the brainstem.

KEYWORDS: Brainstem, Inflammatory

eEdE-28

Pictorial Review of the Imaging Manifestations of Neurosarcoidosis

Nguyen, W.[1]·Ashruf, S.[1]· Endale, B.[1]·Stern, B.[1]·Steven, A.[1]
[1]University of Maryland Medical Center, Baltimore, MD,
[2]University of Maryland Medical Center, Baltimore, MD.

Purpose
Sarcoidosis is an idiopathic multisystem inflammatory disorder known to present with a wide variety of both clinical and imaging manifestations when affecting the neuraxis. By reviewing both the common and uncommon imaging findings of neurosarcoidosis, this exhibit seeks to raise awareness of this disease process.
Approach/Methods
Over 50 cases of neurosarcoidosis were collected to help with this presentation. Cases were collected prospectively in the radiology department, from medical records in the neurology clinic, and by utilizing a search engine to mine the PACS system, all at the University of Maryland Medical Center. All confirmed cases were cross-referenced with the clinical presentation, and clinical and imaging followup when available.
Findings/Discussion
Neurosarcoidosis has a multitude of imaging manifestations which may involve all spaces along the entirety of the neuraxis. Most commonly it presents as leptomeningeal enhancement with preference for the basilar cisterns. Other imaging manifestations include involvement of the cranial nerves resulting in cranial nerve deficits. Neurosarcoidosis also can demonstrate parenchymal involvement, most commonly involving the hypothalamus and brain stem. Spinal neurosarcoidosis is a relatively uncommon manifestation and can present as intramedullary, intradural extramedullary, extradural, vertebral or even disk space lesions. When there is both intra and extramedullary disease, sarcoidosis should be strongly considered as there are few entities which demonstrate both simultaneously. Correlation with imaging outside of the CNS, including the musculoskeletal system and thorax, can aid greatly in diagnosis as over 90% of these patients will have additional systemic findings.
Summary/Conclusion
Neurosarcoidosis has protean imaging and clinical manifestations and often is difficult to diagnose definitively. By understanding its variable imaging manifestations, the neuroradiologist may aid our clinical colleagues in further workup and subsequent management of these complex patients.

KEYWORDS: Sarcoid, Neurosarcoidosis

Completing the Differential: A Comprehensive Discussion of Multiple Sclerosis Mimics

Jewells, V.·Horsley, L. C.
University of North Carolina - Chapel Hill
Chapel Hill, NC.

Purpose
This review will examine the imaging findings, symptoms, pathophysiology, laboratory, and treatment differences of multiple sclerosis (MS) and its many mimics in order to discuss the broad differential of diseases that should be considered during image interpretation.
Approach/Methods
Records were identified by searching an IRB-approved database of 783 patients with MS and MS-like symptomatology with selective review of MR images and clinic notes to address the pathology exhibited at our institution.
Findings/Discussion
Some patients presented with MS-like symptoms and ultimately were diagnosed with unusual medical conditions including chronic inflammatory demyelinating polyneuropathy (CIDP), dilitative arteriopathy (autopsy proven, Figure #1), and HTLV-1. Distinct imaging, laboratory, and clinical findings help pinpoint the correct diagnosis.

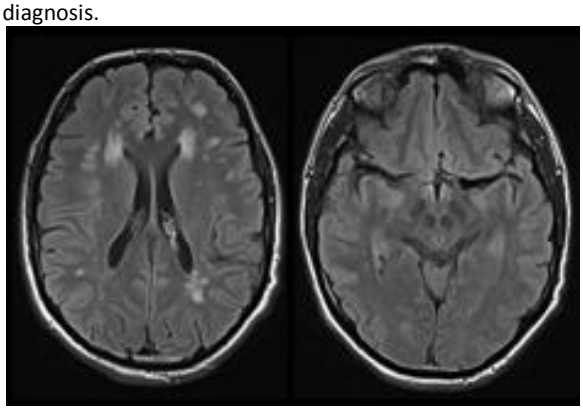

Figure. Thirty-one-year-old caucasian male who presented with MS symptoms, but was proven at autopsy to have no demyelinating lesions, but rather dilitative arteriopathy. FLAIR images are shown. The first image shows multiple abnormal FLAIR signal foci typical of MS lesions. The second image shows ectasia of the bilateral middle cerebral arteries.
Summary/Conclusion
Despite clinical criteria, laboratory tests, and specific

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

brain/spine MRI findings, MS is a diagnosis of exclusion with a large number of disorders that mimic it. Some variants or forms of MS including Balos concentric sclerosis and neuromyelitis optica express positive complement resulting in a more aggressive course, and if suspected need to be addressed in the imaging report. In addition, acute disseminated encephalomyelitis (ADEM), CADASIL, Behçet's disease, progressive multifocal leukoencephalopathy (PML), Sussac's syndrome, HIV encephalopathy, sarcoidosis, systemic lupus erythematosus (SLE), Sjögren's syndrome, Lyme disease, toxoplasmosis, and neoplasms are typically mentioned in the literature as being misdiagnosed as MS, in addition to the rare conditions we also encountered. These processes will be described with regard to their imaging, pathophysiology, and laboratory differences to educate the audience about the many MS mimics.

KEYWORDS: Multiple sclerosis, Differential diagnosis

RadioGenomics and Glioblastoma Multiforme: Update from the TCGA Glioma Phenotype Research Group

Flanders, A. E.[1]·Colen, R. R.[2]·Gutman,, D. A.[3]·Hwang, S. N.[3]·Wintermark, M.[4]·Jain, R.[5]·Jilwan-Nicolas, M.[4]·Chen, Y. J.[6,7]·Raghavan, P.[4]·Holder, C. A.[3]·Rubin, D.[8]·Erickson, B.[9]·Huang, E.[10]·Kirby, J.[10]·Freymann, K.[10]·Jaffe, C. C.[11]·TCGA Glioma Phenotype Research Group
[1]Thomas Jefferson University Hospital, Philadelphia, PA, [2]M. D. Anderson Cancer Center, Houston, TX, [3]Emory University, Atlanta, GA, [4]University of Virginia, Charlottesville, VA, [5]Henry Ford, Detroit, MI, [6]University of California San Diego Health System, San Diego, CA, [7]San Diego Medical Center, San Diego, CA, [8]Stanford University, Stanford, CA, [9]Mayo Clinic, Rochester, MN, [10]NCI/NIH, Bethesda, MD, [11]NCI/NIH, Rockville, MD.

Purpose
Imaging features of cancers are phenotypic expressions of the tumors genomic blueprint. The term "radiogenomics" or the phrase "genomic imaging" has been applied to the concept of bridging these relationships between imaging and genomics in clinical research. Opportunities to systematically marry the rich imaging features provided by MR imaging to genetics of cancer have been limited to small cohorts and exploration of limited imaging features. The Cancer Genome Atlas (TCGA) has been banking large volumes of tumors for comprehensive genomic analysis. The first tissue line collected by TCGA was glioblastoma multiforme (GBM). Concurrently, the Cancer Imaging Program (CIP) collected baseline MRI studies on each of the TCGA submissions into a secure repository known as the Cancer Imaging Archive (TCIA). The purpose of this exhibit is to summarize the collective work of the TCGA Glioma Phenotype Research Group - an ad hoc volunteer committee focused on advancing the complementary role of imaging in understanding the biological and clinical behavior of GBM.
Approach/Methods
The TCGA Glioma Phenotype Research group initially developed, vetted and tested a controlled vocabulary of comprehensive MRI features of GBM. This VASARI featureset captures 30 unique imaging characteristics that are familiar to neuroradiologists in the evaluation of brain tumors. Using this methodology, the baseline imaging features of over 130 glioblastomas have been recorded by three or more independent observers. Subsets of physiologic imaging characteristics such as dynamic susceptibility contrast (DSC perfusion) and diffusion tensor imaging (DTI) were utilized for related analyses.
Findings/Discussion
Through this unique collaborative effort, eight other distinct research arms have been initiated from this single project that focused on the interrelationship of the 30 subjective MRI features (VASARI featureset) and the genetics of GBM. These include: (1) DSC T2* MR perfusion analysis which examines the combination of perfusion metrics and molecular characteristics to improving ability to predict survival; (2) Forecasting disease-free interval and survival using combined modeling of clinical parameters, imaging and genomics; (3) Mapping of edema/cellular invasion to MR phenotypes using MRI volumetrics and large-scale gene and microRNA expression profiling in GBM; (4) A growth kinetic study to predict growth pattern of GBM based upon features on baseline MRI, (5) Man-machine correlation of cardinal MR imaging features scored between human and machine observers; (6) Prediction of histopathologic, genomic and clinical features from DTI characteristics of GBM; (7) A computer-aided detection (CAD) texture analysis which uses multispectral features including intensity, texture and morphology to identify important features that predict genetic patterns; and (8) Supervised and unsupervised clustering of GBM into semantically distinct categories using imaging derived features.
Summary/Conclusion
Imaging has a much greater role to play in oncology than just diagnosis and staging. There is a complementary role between clinical parameters, imaging and genetics that can improve upon current methods to predict disease type, response to treatment and overall survival in GBM. The collective work of the TCGA Glioma Phenotype Working Group serves as a model for efficient collaboration and discovery.

eEdE-31

Spectrum of Neuroimaging Findings in Radiation-Related Central Nervous System Lesions

Gocmen, R.·Guler, E.·Guler, I.·Ozgen, B.·Oguz, K.
Hacettepe University
Ankara, TURKEY.

Purpose
To review the imaging features and discuss the approach to the differential diagnosis of radiation-induced injury in the central nervous system (CNS).
Approach/Methods
The computed tomography and magnetic resonance imaging findings of patients who had undergone radiation therapy and developed radiation-related lesions in CNS were reviewed for this educational exhibit.
Findings/Discussion
The various types of radiation-induced changes of brain will be described and characterized. These include: radiation necrosis, diffuse white matter injury, focal white matter lesion, vascular lesions (pseudoaneurysm, telangiectasia, cavernoma, arteriovenous malformation, vasculitis), mineralizing microangiopathy, transient focal contrast enhancement, secondary neoplasm, stroke-like migraine attacks after radiation therapy (SMART), necrotizing leukoencephalopathy.
Summary/Conclusion
Radiation therapy is used frequently for the treatment of neoplastic or nonneoplastic CNS disorders such as arteriovenous malformations. With the growing use of high dose radiation therapies such as cyberknife or gamma knife, radiation-induced injuries are increasingly encountered. The radiologists should be familiar with the imaging characteristics and differential diagnosis with essentially brain tumor in these lesions.

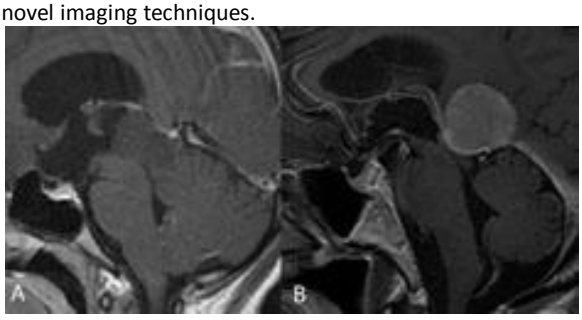
KEYWORDS: Radiation injury, Cerebral radiation necrosis, MR imaging

eEdE-32

3 Square Centimeters. Anatomy and Pathology of the Posterior Third Ventricle, Pineal and Quadrigeminal Plate Region: A Neuroradiographic Review

Fredriksen, J. R.·Morris, J. M.
Mayo Clinic
Rochester, MN.

Purpose
To demonstrate the imaging appearance of the normal anatomy and pathology of lesions occurring in the posterior third ventricle, pineal region, quadrigeminal plate, quadrigeminal plate cistern, velum interpositum, and internal cerebral veins.
Approach/Methods
After obtaining IRB approval we retrospectively searched the pathology, surgery, radiology, and clinical institutional databases for pathologic diagnosis of lesions in the above states regions over a 15-year time frame. Specifically search terms including the anatomical location as well as the varied pathologies that can occur in these locations were queried. This included but was not limited to pineal gland, internal cerebral veins, posterior commissure, Habenular commissure, Velum Interpositum, thalamus, choroid plexus, quadrigeminal plate, aqueduct of Sylvius, third ventricle, tectum, superior and inferior colliculus, epidermoid, teratoma, dermoid, quadrigeminal plate glioma, primary pineal neoplasm of indeterminate grade, pineocytoma, pineoblastoma, papillary tumor of the pineal gland, germinoma, mixed germ cell neoplasm, meningioma, ependymoma, subependymoma, choroid plexus papilloma, choroid plexus carcinoma, pilocytic astrocytoma, splenium corpus callosum, aqueductal stenosis, cavernous hemangioma, trilateral retinoblastoma, pineal cyst, lipoma, pineal metastasis, vein of Galen aneurysm, arteriovenous malformation, internal cerebral vein thrombosis, and dural arteriovenous fistula. We then reviewed the available imaging and detailed the distinguishing imaging characteristics, age and clinical history that allowed lesions to be differentiated from one another.
Findings/Discussion
Lesions that occur in the posterior third ventricle, pineal, and quadrigeminal plate region are often large at the time of diagnosis making site of origin difficult to pinpoint. Since many of the lesions ultimately go on to biopsy it is helpful to the referring neurosurgeon to have as much information as possible before performing a biopsy or if a biopsy is even necessary. We describe in this educational exhibit ways to help the neuroradiologist narrow the differential diagnosis using anatomical clues, age of the patient, available laboratory data, clinical history, and novel imaging techniques.



Summary/Conclusion
A wide array of pathologic entities and normal variants can occur in this 3 squared centimeter region of the brain. After the conclusion of viewing this educational exhibit the radiologist will be able to provide a meaningful, concise, and clinically relevant differential diagnosis to the referring clinicians.

KEYWORDS: Pineal gland, Third ventricle, quadrageminal plate

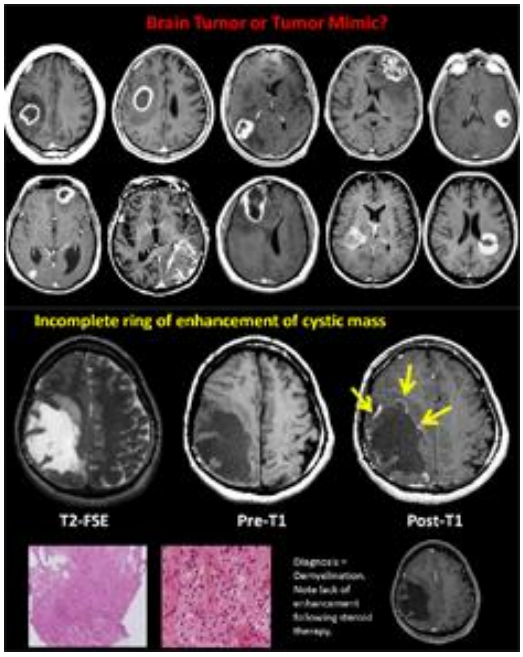
Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eEdE-33

Mimics of Brain Tumor at Neuroimaging with Clinicopathologic Correlation

Starkey, J.·Tihan, T.·Cha, S.
University of California San Francisco
San Francisco, CA.

Purpose
To review the CT and MRI features that differentiate tumor mimics from brain tumors.
Approach/Methods
We retrospectively reviewed the CT and MR imaging of all patients without prior intracranial abnormality who were referred to our institution for resection of lesions initially interpreted as tumor and later proven non-neoplastic on pathology. For these cases, we reviewed the imaging findings that potentially aid in prospective diagnosis of tumor mimicking entities.
Findings/Discussion
Of 956 cases identified, 120 (12.6%) were pathologically proven to be non-neoplastic: 56 abscess/infection, 25 demyelination disease, 15 vascular (cavernous angioma, hemangioma, venous telangiectasia, organized hematoma), 8 radiation necrosis (with prior non-melanomatous head/neck or skin primary malignancy treated with external beam radiation), 7 subacute ischemia, 7 angiitis/vasculitis/nonspecific inflammation, and 2 astrogliosis. Five imaging findings suggestive of tumor mimics include 1) T1 hyperintensity, 2) smooth and complete rim of T2 hypointensity, 3) homogeneously reduced diffusion, 4) rim of leading edge reduced diffusion, and 5) incomplete ring enhancement in a cystic lesion. Prior history of radiation therapy that included irradiation of a part of brain was the most helpful in the diagnosis of radiation necrosis in a patient presenting with aggressive-appearing brain mass. We provide CT, MR, and histopathology images for representative cases, including gyral T1 shortening in subacute ischemia, smooth peripheral T2 shortening in cavernous angioma, homogeneously reduced diffusion within a ring enhancing mass including pyogenic abscess, tuberculoma, nocardia, and neurocysticercosis, leading edge peripheral reduced diffusion within an angioinvasive aspergillosis brain abscess, temporal lobe FLAIR hyperintensity with reduced diffusion in herpes encephalitis, incomplete ring enhancement in cystic tumefactive demyelination, and irregular rim enhancement with surrounding edema in radiation necrosis.



Summary/Conclusion
While tumor mimics share many imaging features with neoplastic brain lesions, they have specific MRI features that aid in preoperative diagnosis, avoiding unnecessary surgical resection and allowing appropriate clinical management.

KEYWORDS: Neoplasm, mimic

eEdE-34

Granulocytic Sarcoma: What the Radiologist Needs to Know Regarding Granulocytic Sarcoma and Other Associated Conditions

Chaudhry, A.[1]·Hoefling, N. L.[1]·Gul, M.[2]·Peyester, R.[1]
[1]Stonybrook University Medical Center, Stonybrook, NY,
[2]Winthrop University Hospital, Mineola, NY.

Purpose
Granulocytic (myeloid) sarcoma can be the initial presentation of aleukemic leukemia that either resulted from myelodysplastic syndrome conversion into leukemia, de novo aleukemic leukemia or leukemia relapse. It can present weeks to months before the peripheral presence of the leukemia. Although granulocytic sarcoma carries a broad differential diagnosis, it can be narrowed utilizing age, clinical features, and imaging characteristics of the lesion, such as location, enhancement pattern and presence of necrosis. By the conclusion of this presentation, the radiologist should have a better understanding of various clinical presentations of granulocytic sarcoma and relevant imaging and pathologic findings.
Approach/Methods
We present a case-based review of the clinical features, imaging, pathophysiology, histologic features, treatments

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

and prognosis of granulocytic (myeloid) sarcoma also known as chloroma. We will describe the characteristic imaging (CT and MRI) features of granulocytic sarcoma. Information will be presented on the various conditions associated with granulocytic sarcoma such as myelodysplastic syndrome and acute myelogenous leukemia; clinical presentation and histopathologic findings of each entity are discussed.
Findings/Discussion
Multiple different presentations of granulocytic sarcoma will be shown, including brain parenchymal, ventricular, submandibular, orbital and spinal. We also will show cases of similar appearing entities such as lymphoma, metastases, infection, tuberculosis, astrocytoma, sarcoma, sarcoidosis, hemangiopericytoma and malignant fibrous histiocytoma, with an emphasis on differentiating these from granulocytic sarcoma. Additional processes resulting from infection, inflammation, injury and/or malignancy that may mask and/or mimic granulocytic sarcoma will be discussed with emphasis on key points which help to narrow the differential diagnosis.
Summary/Conclusion
Granulocytic sarcoma is a rare pathology that can be the initial manifestation of aleukemic leukemia. Knowledge of the imaging characteristics and differential considerations can play an important role and aid in the early diagnosis of this disease.

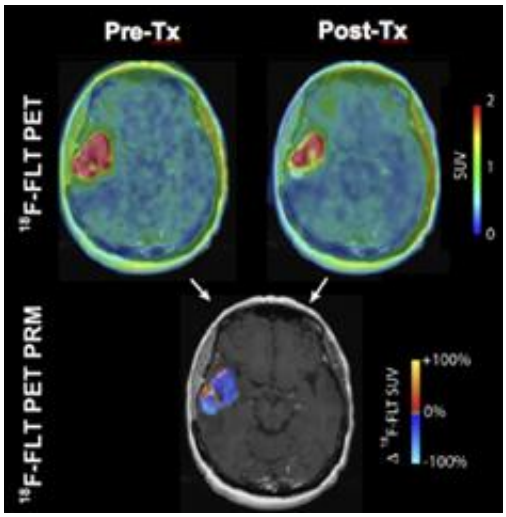
KEYWORDS: Cancer, Leukemia

eEdE-35

PET Parametric Response Maps as a Clinical Tool for Clinical Monitoring and Predicting Treatment Response in Diffuse Gliomas

Ellingson, B. M.·Harris, R. J.·Chen, W.·Czernin, J.·Phelps, M. E.·Cloughesy, T. F.·Pope, W. B.
David Geffen School of Medicine at University of California Los Angeles
Los Angeles, CA.

Purpose
PET tracers have demonstrated superior specificity for identifying regions of metabolically active brain tumors; however, single time-point evaluations of tumor tracer uptake fail to reflect temporal changes in tumor metabolic behavior and lack insight into the spatial heterogeneity of tumor growth and/or response to therapy. The purpose of this study is to highlight the value in 18F-FDG, 18F-FDOPA and 18F-FLT PET parametric response maps (PRMs) as a tool clinical evaluation of patients with diffuse gliomas.
Approach/Methods
PET PRMs are calculated by performing voxel-wise subtraction between tracer standard uptake value (SUV) on a current PET scan (e.g., during treatment) and a previous (baseline) scan after registration to the same image space. Specifically, baseline PET images are first aligned to a baseline MR images, the post-treatment MR image then is registered to the pretreatment MR image, and the registration matrix is applied to the corresponding post-treatment PET images. Voxel-wise subtraction between the uptake values then is performed on the PET images; alternatively, the percentage change in uptake can be calculated. Finally, a threshold for difference in tracer uptake based on normal variability in normal-appearing tissue is used to determine whether voxels are significantly different. The resulting volume and volume fraction of significantly increasing, decreasing, or changing voxels in a tumor region are used to define PET PRMs.
Findings/Discussion
PET PRMs using either 18F-FDG, 18F-FDOPA or 18F-FLT PET tracers can be used to quantify spatially-specific tumor growth characteristics and response to specific therapies in diffuse gliomas. PET PRMs show significantly better sensitivity for detecting regional metabolic changes compared with standard ROI-based and visual assessments of serial PET scans.



Summary/Conclusion
PET PRMs are a novel technique for automated quantification of metabolic changes during clinical evaluation and treatment of brain tumors. Future studies aimed at validating the spatial specificity are warranted.

eEdE-36

CT and MR Imaging of Intracranial Cystic Lesions: A Practical Location-Based Approach

Hakham, S.·Prober, A.·Madan, N.·Do-Dai, D. D.
Tufts Medical Center
Boston, MA.

Purpose
The purpose of our exhibit is to present a simplified, yet comprehensive and systematic approach for analyzing intracranial cystic lesions based on lesion location and CT and MR appearance. An appropriate differential diagnosis for each lesion is entertained, with specific discussion of

management: which lesions require intervention or followup, and which can be forgotten.
Approach/Methods
Sample cases from our institution are utilized to present a pictorial review of typical and atypical intracranial cystic lesions and provide a systematic, location-based algorithm to formulate an accurate differential diagnosis. Where appropriate, pitfalls, mimics, and complicating features will be discussed and histopathologic correlation will be reviewed.
Findings/Discussion
While some lesions, such as cystic neoplasms, require further intervention, numerous benign or probably benign lesions can be ignored or followed. However, developing a systematic approach can be useful in formulating an accurate differential diagnosis based on the lesion location, morphology, and presence or absence of complicating features. Moreover, such an approach can facilitate management decisions. Intra- and extra-axial cystic lesions including cystic neoplasms, infectious cysts, and true cysts are discussed, with specific attention to the next step in management. Additional emphasis is given to the location of the lesion as a clue for a more accurate diagnosis. For instance, while pineal cysts, dermoids, Rathke cleft cysts, and suprasellar arachnoid cysts are seen more often as midline extra-axial lesions, epidermoids, neurocysticercosis, arachnoid cysts, and neurenteric cysts are among diagnoses to be more expected as off-midline extra-axial cystic lesions. Intra-axial parenchymal lesions may present as porencephalic cysts, neuroglial cysts, or enlarged prevascular spaces. Lastly, choroid plexus cysts, ependymal cysts, and colloid cysts are seen most commonly as intra-axial, intraventricular cystic lesions.
Summary/Conclusion
Our educational exhibit aims to provide the practicing neuroradiologist with a framework for approaching the various intracranial cystic lesions in a systematic manner to effectively provide an appropriate differential diagnosis for each lesion and an approach to management.

Cerebellopontine Angle Mass: An Interactive, Case-Based Review

Thurlow, P. C.·Fukui, M. B.·Goldberg, M. F.
West Penn Allegheny Health System
Pittsburgh, PA.

Purpose
The differential diagnosis of common cerebellopontine angle (CPA) masses is one of the most well known in all of neuroradiology. These include: meningioma, schwannoma, epidermoid cyst, arachnoid cyst, and metastasis. However, the neuroradiologist must be aware of and recognize the less common pathology that can occur at the CPA. The purpose of this exhibit is to show the various disease processes that occur at the CPA via an interactive, case-based review.
Approach/Methods
This educational exhibit will: 1) Review normal CPA anatomy, including relevant osseous, vascular, and cranial nerve anatomy. 2) Review the common pathologic processes that occur at the CPA. Comment will be made on key
diagnostic clues and pitfalls, as well as important “do not touch” lesion mimics. 3) Review rare pathologic processes that occur at the CPA. These include, but are not limited to: fat necrosis, radiation necrosis, ganglioglioma and chrondrosarcoma. Comment will be made on key diagnostic clues and pitfalls. 4) Provide a diagnostic strategy that can be employed by the radiologist upon encountering a CPA mass. 5) Provide an interactive case-based review and self-assessment quiz to reinforce key teaching points.
Findings/Discussion
The participant will learn a strategy for diagnosing CPA masses that emphasizes identifying lesion location and extension to critical adjacent anatomy, typical imaging features, and imaging technique. The CPA is composed of multiple components, including subarachnoid/CSF space, osseous skull base, arterial and venous vasculature, cranial nerves, dura, cerebullum, and brainstem. With a greater understanding of this anatomy, as well as the use of conventional and advanced imaging techniques, the participant will be given a strategy for precisely identifying the wide range of common and uncommon pathologies that can occur at the CPA.
Summary/Conclusion
The diagnosis of CPA pathology can be challenging, at times, for the radiologist. Achieving the correct diagnosis is critical for therapeutic decision-making, prognostication, and improved patient outcomes. This interactive education exhibit provides a review of CPA anatomy and highlights key features to distinguish the various potential etiologies of CPA pathology.

Cysts in the Brain: To Worry or Not to Worry?

Rohatgi, S.[1,2]·Hsu, L.[1,2]
[1]Brigham and Women's Hospital, Boston, MA, [2]Harvard Medical School, Boston, MA.

Purpose
1. To illustrate the imaging spectrum of cystic lesions in the brain using case-based examples. 2. Differential diagnosis and clinical presentation based on anatomical location. 3. Key imaging pearls of commonly encountered cysts and cystic lesions. 4. Recognize benign from neoplastic cysts, hence prevent unnecessary interventions.
Approach/Methods
We approached various cystic lesions, using an origin and

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

location-based algorithm. Clinical features and imaging appearances on CT and MR are discussed with key pertinent differential diagnosis and management.
Findings/Discussion
Cysts or cystic lesions are often benign incidental findings and usually asymptomatic. Some cysts, however, are associated with tumors. Differential of cysts or cystic lesions can be approached according to their origin, pathogenesis or anatomical location. It is important to recognize and differentiate benign or developmental cysts from tumor-associated cysts as these have vastly different prognosis. Familiarity with the imaging spectrum may prevent unnecessary biopsy/surgery. MR imaging currently is the diagnostic modality of choice in characterization of cystic lesions, although there are instances where CT is complementary to MRI, especially in detection of calcification or hemorrhage.
Summary/Conclusion
Cystic lesions can at times pose a diagnostic dilemma because of their varied locations and appearances. Awareness of the imaging characteristics of these lesions is important for prognosis as well as prevention of unnecessary interventions. This educational exhibit reviews imaging spectrum of cystic lesions based on their location, diagnostic imaging pearls and their differential diagnosis.

KEYWORDS: Cysts, location, imaging

eEdE-39

T1-Weighted Dynamic Contrast-Enhanced and T2*-Weighted Dynamic Susceptibility Contrast MR Imaging - Physical Principles, Techniques and Clinical Applications in Neuro-Oncology: What the Neuroradiologist Needs to Know

Hoque, K. E.[1]·Huhdanpaa, H.[1]·Hwang, D. H.[1]·Muradyan, N.[2]·Booker, M. T.[1]·Russell, S.[1]·Sivasundaram, L.[1]·Naghi, I.[1]·Kim, P. E.[1]·Lerner, A.[1]·Law, M.[1]·Shiroishi, M. S.[1]
[1]University of Southern California, Los Angeles, CA, [2]iCAD, Inc., Los Angeles, CA.

Purpose
The purpose of this exhibit will be to provide a comprehensive overview of the physical principles, techniques and clinical applications of T1-weighted dynamic contrast-enhanced (DCE) and T2*-weighted dynamic susceptibility contrast (DSC) MRI in a case series of neuro-oncology patients.
Approach/Methods
1. Tumor biology. 2. Physical principles and techniques of DCE and DSC MRI. 3. Clinical applications of DCE and DSC MRI in neuro-oncology patients. 4. Pitfalls. 5. Future of DCE and DSC MRI.
Findings/Discussion
1. Tumor biology: An overview of tumoral angiogenesis and a focus on VEGF will be provided. 2. Physical principles and techniques of DCE and DSC MRI: Relevant concepts involving image acquisition, postprocessing and interpretation will be provided. 3. Clinical applications of DCE and DSC MRI in neuro-oncology patients: An overview of tumor diagnosis, prognosis, therapy selection and therapeutic evaluation will be provided. 4. Pitfalls: Common pitfalls and controversies regarding DCE and DSC MRI in neuro-oncology will be discussed. 5. Future of DCE and DSC MRI: A discussion of future applications and challenges facing DCE and DSC MRI in neuro-oncology will be provided.
Summary/Conclusion
This education exhibit will provide the neuroradiologist with an in-depth review of the relevant concepts underlying the technical and clinical aspects of DCE and DSC MRI in the context of the brain tumor patient through a case series. It is hoped that this will better enable integration of these functional MRI techniques into their clinical practice.

KEYWORDS: Dynamic contrast enhancement, Dynamic susceptibility contrast-enhanced

eEdE-40

Neuroradiology Jeopardy

Maralani, P. J.·Mohan, S.
University of Pennsylvania
Philadelphia, PA.

Purpose
In this interactive jeopardy game we will review the imaging findings of 31 important diagnoses in neuroradiology. The cases are presented the same way they were brought to our attention by the clinical services. It is designed to increase diagnostic accuracy of the trainees with particular emphasis on imaging findings. The game is at the level of a senior radiology resident or a neuroradiology fellow.
Approach/Methods
Our jeopardy game consists of six categories including: 1) Brain tumor; 2) Infectious, inflammatory and toxic/metabolic pathologies; 3) Vascular pathologies; 4) Head and neck pathologies; 5) Spine; and 6) Potpourri. In each category there are six cases in increasing order of complexity. There will be a final jeopardy case of traumatic brain contusion that involves multimodality imaging, with stress on CT diagnosis and review of the findings on MRI.
Findings/Discussion
Figure 1 demonstrates the format of the game. Table 1 demonstrates the cases that will be presented. In each case we will review the imaging and pertinent clinical

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

findings that help narrow down the differential diagnosis.

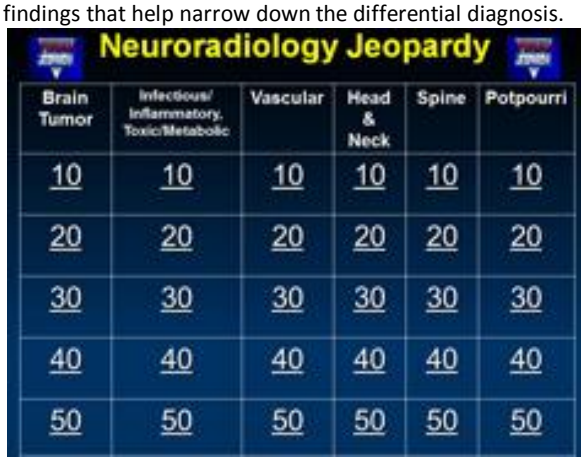

Table 1.

Brain Tumor	Infectious/Inflammatory, Toxic/Metabolic	Vascular	Head & Neck	Spine	Potpourri
GBM	Herpes encephalitis	Arteriovenous malformation	Peritonsillar abscess	Chance Fracture	Fibrous Dysplasia
Epidermoid	Global hypoxic injury	Vertebral artery aneurysm	Otosclerosis	Diskitis/Osteomyelitis	Tumefactive Perivascular Spaces
Lymphoma	Basal tuberculosis meningitis	Moyamoya disease	Venolymphatic Malformation	Dural AV fistula	Intracranial Hypotension
Gliomatosis cerebri	Progressive multifocal leukoencephalopathy	Capillary telangiectasia	Ameloblastoma	Devic's Disease	Thrombophlebitis superficial neck veins
Cardiac myxoma with hemorrhagic brain metastasis	Pseudohypoparathyroidism	CADASIL	Endolymphatic Sac Tumor	Myxopapillary Ependymoma	Hyperammonemia, Hepatic Encephalopathy

Summary/Conclusion
This presentation serves as an interactive teaching tool for senior radiology residents and fellows. It emphasizes on several important imaging findings in neuroradiology that will help reach the final diagnosis. This exposition also can be used as an evaluation tool for trainees to assess their readiness in diagnostic neuroradiology.

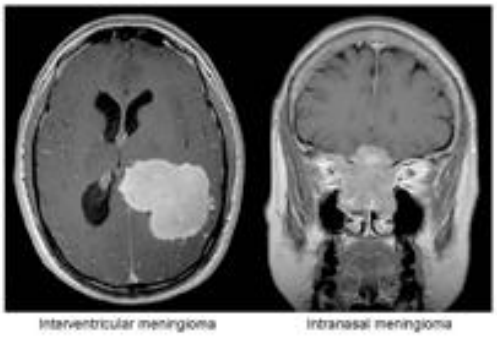
eEdE-41

Meningiomas: Morphologic Manifestations and Mimics on MR and CT

Thuahnai, S. T.·Lindsay, A.·Boyer, P.·Rubenstein, D.
University of Colorado Denver
Denver, CO.

Purpose
Classically meningiomas are described as avidly enhancing dural-based extra axial masses, but the MRI and CT appearance may be variable. The purpose of this exhibit is to present the various MRI and CT findings of meningiomas.
Approach/Methods
We retrospectively reviewed the imaging of meningiomas and mimics that were biopsy proven in our institution. The imaging was reviewed for anatomical location, signal characteristics on MRI or density on CT, type of enhancement and involvement of adjacent structures. Imaging features were correlated with other pathologic diagnosis and grading.
Findings/Discussion
While the classic dural-based extra axial mass is a typical presentation for a meningioma, there are other variations. When dural-based they are found mostly supratentorially with clear attachment to the convexity, dura or falx. Infratentorial involvement can occur along the clivus, tentorium cerebelli, along the cerebellopontine angles, jugular foremen and in the spine. Less common locations are intraosseous, intranasal and intraventricular. Other dural-based or superficially located parenchymal neoplasms can mimic meningiomas.



Summary/Conclusion
Meningiomas can have a variety of appearances on CT and MRI. They can occur in locations that are atypical and their typical appearance may be mimicked by lesions of other etiology. Imaging findings may not be suggestive of the WHO grade of the meningiomas.

KEYWORDS: Meningioma, Variants, mimics of dural-based lesions

eEdE-42

Ten Tumors Under the Tent: Posterior Fossa Masses

Linscott, L.·Wippold, F.·Miller-Thomas, M.
Mallinckrodt Institute of Radiology
St. Louis, MO.

Purpose
Present the imaging findings of common posterior fossa masses. Emphasis will be on characteristic imaging features of each diagnosis, important clinical discriminators, and pitfalls in diagnosis.
Approach/Methods
1. Cases will be identified from our clinical practice in both a large tertiary care adult medical center and large tertiary care children's hosptital. Imaging modalities presented will include MRI, CT, PET, and angiography. 2. Discuss differentiating imaging features and clinical pearls of the following posterior fossa masses: - Metastasis, - Hemangioblastoma, - Ependymoma, - Medulloblastoma, - Juvenile pilocytic astrocytoma, - Dysplastic gangliocytoma, - Brainstem glioma, - Meningioma, - Atypical Teratoid Rhabdoid Tumor, and - Dermoid/Epidermoid. 3. Present an

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

interactive quiz based on the presented cases designed to reinforce key concepts.
Findings/Discussion
Posterior fossa masses are encountered commonly in both adults and children. While age plays an important role in determining the differential diagnosis, imaging features help to narrow the differential and often suggest a most likely diagnosis. Just a few examples of such imaging features to be discussed include; contrast enhancement equal to blood pool with flow voids strongly suggests hemangioblastoma rather than other cystic posterior fossa lesions; hyperattenuation on CT in a pediatric cerebellar mass suggests medulloblastoma as the most likely diagnosis; extension of tumor through the foramina of Luschka and Magendie strongly suggests ependymoma as the most likely diagnosis; Diffusion-weighted imaging is critical for the evaluation of cystic posterior fossa masses to differentiate such lesions as epidermoid and arachnoid cysts. Some examples of potential diagnostic pitfalls include; increased FDG radiotracer uptake in nonaggressive lesions such as dysplastic gangliocytoma; a dural tail is not pathognomonic for meningioma.
Summary/Conclusion
Posterior fossa masses are commonly encountered and many have distinctive imaging appearances. The workup and management of these entities varies greatly. Knowledge of distinctive imaging findings helps the radiologist to narrow the differential diagnosis, guide management decisions, and avoid diagnostic pitfalls.

KEYWORDS: Posterior fossa, Masses

Multimodal Imaging of Neurocutaneous Syndromes: A Pictorial Review

Ibrahim, S. M.·Bokhari, S. J.·Bronen, R.·Mahajan, A.·Malhotra, A.
Yale University School of Medicine
New Haven, CT.

Purpose
The objective of this presentation is to discuss the pathophysiology, genetics, and clinical presentation of the following neurocutaneous syndromes: 1) Tuberous sclerosis (TS); 2) Neurofibromatosis types 1 (NF1) and 2 (NF2); 3) von Hippel-Lindau (VHL); and Sturge Weber syndrome (SW).
Approach/Methods
Cross-sectional imaging has become increasingly important in recognizing features of neurocutaneous syndromes. The role of CT, MRI, MR spectroscopy, PET and diffusion tensor imaging will be discussed in the diagnosis of these neurocutaneous syndromes. The characteristic features of each of these neurocutaneous syndromes will be highlighted.
Findings/Discussion
The pathophysiology and genetic basis for TS, NF1, NF2, VHL and SW will be discussed in addition to the imaging features. The diagnostic criteria will be highlighted with emphasis on the differential diagnoses specific to each neurocutaneous syndrome.
Summary/Conclusion
Multimodality imaging plays an important role in the diagnosis of neurocutaneous syndromes. It is important for the radiologist to recognize the complex and sometimes salient features of these rare entities.

KEYWORDS: VHL, Phakomatoses, NF1 and 2

eEdE-44

Primary Central Nervous System Lymphoma: An Interactive Pictorial Review of Common and Uncommon Imaging Presentations

Wang, Y.[1]·Hanagandi, P. B.[1]·Goncalves, F. G.[2]·Chong, J.[1]·Bessissow, A.[1]·Chankowsky, J.[1]·del Carpio-O'donovan, R.[1]
[1]Montreal General Hospital, McGill University, Montreal, QC, CANADA, [2]Radiologia Infinita - Brasilia Children's Hospital, Brasilia, BRAZIL.

Purpose
In this interactive educational exhibit, we emphasize the characteristic CT and MR imaging features depicting the presentation and evolution of primary CNS lymphoma.
Approach/Methods
After a review of imaging features, we present typical and atypical examples of primary CNS lymphoma in immunocompetent and immunocompromised patients, as wells as lymphoma mimics, in an interactive case-based format. Each case is accompanied by a brief discussion.
Findings/Discussion
Primary CNS lymphoma is a predominantly B-cell lymphoma, and represent over 6% of all primary brain tumors. It has a diffuse microscopic growth pattern, distinct perivascular extension, and a predilection for the basal ganglia or periventricular regions. On imaging, the high cellularity of tumors appears hyperattenuating on noncontrast-enhanced CT, with low to intermediate signal intensity on T2-weighted MR images and enhancement. Internal hemorrhage and necrosis present in immunocompromised individuals may create a diagnostic dilemma. Although sensitive to chemotherapy and radiotherapy, often with dramatic disappearance of lesions on follow-up radiologic studies, aggressive tumor recurrence is common and the overall prognosis is poor.
Summary/Conclusion
Primary CNS lymphoma is an increasingly prevalent intracranial neoplasm with nonspecific clinical presentation. Its imaging appearance, especially in immunocompromised individuals, may mimic other intracranial neoplasms and infectious or inflammatory etiologies. This interactive review from our institution will better familiarize radiologists with typical and atypical

imaging features, differential diagnosis, and locations of primary CNS lymphoma on CT and MRI.

KEYWORDS: Lymphoma, Brain neoplasms

eEdE-45

MR Imaging Findings of Ipilimumab-Related Hypophysitis

Jones, K. S.·Baykal, A.·Gabriel, R.
Virginia Commonwealth University Health System
Richmond, VA.

Purpose
Cytotoxic T-lymphocyte-associated antigen 4 (CTLA-4) blocking agents may cause adverse events related to their activity on the immune system. Ipilimumab, a monoclonal antibody effective in treating metastatic melanoma, has induced autoimmune syndromes such as enteritis, thyroiditis, dermatitis, and hypophysitis. We present the clinical and imaging findings of a patient with metastatic melanoma, who developed acute Addisonian crisis secondary to Ipilimumab-related autoimmune hypophysitis (AH).
Approach/Methods
A 58-year-old woman with metastatic melanoma postresection of a solitary brain metastasis and whole brain radiation developed progressive fatigue, headache, vomiting and subsequent acute mental status deterioration 3 months after initiating Ipilimumab treatment. She presented to the emergency room after becoming acutely aphasic, agitated, and immobile. Urgent brain MRI demonstrated enlargement of the pituitary gland with heterogeneous signal, enhancement, and possible hemorrhage. Upon admission she became rapidly hypotensive and was found to have marked hyponatremia, hypopituitarism, and adrenal crisis.
Findings/Discussion
Autoimmune hypophysitis can be divided into primary and secondary subtypes. Primary AH includes lymphocytic, the most common type often associated with pregnancy, granulomatous and xanthogranulomatous hypophysitis. Secondary AH occurs due to systemic disease such as sarcoid, Langerhans cell histiocytosis, or Wegeners granulomatosis, sequelae of adjacent intracranial masses or infection, or as most recently described by adverse drug effects such as from chemotherapy. The CTLA-4 gene functions to down regulate T-lymphocytes. Mutations in this gene are associated with a variety of autoimmune diseases. Similarly, antibody suppression of CTLA-4 can augment the body's immune response against tumor.Cytotoxic T-lymphocyte-associated antigen-4 blocking immunotherapies such as Ipilimumab have a demonstrated effect on metastatic melanoma and renal cell carcinoma. Previous reports of anti-CTLA-4 or Ipilimumab induced hypophysitis have described enlargement of the pituitary gland, usually with homogeneous enhancement on MRI. Imaging findings were generally nonspecific, including diffuse enlargement of the gland with loss of bright signal in the posterior pituitary and variable involvement of the infundibulum. By distinction, our patient presented with heterogeneous enlargement of the pituitary gland with possible hemorrhage. Since the brain lesion previously resected had been a hemorrhagic melanoma metastasis, initial differential considerations included primary pituitary processes such as hypophysitis or apoplexy versus a hemorrhagic metastatic lesion to the pituitary gland.Reported clinical presentations of AH have ranged from solitary hormonal derangements to panhypopituitarism. Isolated ACTH deficiency is the most common pituitary hormone defect, usually iatrogenic from glucocorticoid administration. This was the critical deficiency causing adrenal crisis and shock in our patient. The severity of our patient's hypophysitis and resulting adrenal crisis required ICU care including stress dose steroids and pressor support. She recovered over the course of several days, was discharged successfully, and has been treated as an outpatient with a long course of low dose steroids. On follow-up MRI, pituitary gland size returned to normal without evidence of residual hemosiderin thus excluding the possibility of apoplexy or hemorrhagic metastasis. While Ipilimumab was discontinued after the acute hospitalization, she has remained in remission to date.
Summary/Conclusion
This unique imaging presentation provides the radiologist insight into the complexities of a promising new chemotherapeutic agent.

A Web-Based Mobile Application for Learning and Reviewing the Appearance of Intraventricular Masses Using a Multimodality Approach

Horn, C.·Kadoch, M. A.·Sicular, S.·Ward, T. J.·Fitzpatrick, D.·Naidich, T.
Mount Sinai Medical Center
New York, NY.

Purpose
The purpose of the exhibit is: 1. To provide quick and easy access to a web-based mobile application and reference guide that addresses most of the common intraventricular masses as evaluated by modern imaging modalities. 2. To provide a reference tool that addresses the limitations of other online reference tools, which can be cost-prohibitive, require log-ins or registration, lack interactivity, and are often slow to engage the end user. 3. To provide imaging of both the specific and nonspecific imaging features of a given intraventricular mass. 4. To provide a novel learning platform that is fully functional using either the internet alone or on most major handheld devices and tablets, which are becoming increasingly important as educational resources for fellows, trainees,

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

and students.
Approach/Methods
All intraventricular masses encountered at our institution since 2001 were reviewed for potential inclusion in the exhibit.
Findings/Discussion
The major teaching points of this exhibit are: 1. Reviewing the diagnostic as well as nonspecific imaging findings of multiple intraventricular masses on modern imaging modalities. 2. Encouraging each user to expand on this review by linking each pathology to important AJNR articles that further discuss that specific pathology. 3. Measuring the success of this electronic educational exhibit by monitoring number of online views and traffic directed towards the supplied AJNR articles.
Summary/Conclusion
A web-based mobile application for learning and reviewing the appearance of intraventricular masses using a multimodality approach is presented.

KEYWORDS: Intraventricular, Neoplasm

MR Imaging in the Evaluation of Brain Metastases Treated with Stereotactic Radiosurgery

Almeida-Freitas, D. B.[1]·Carvalho, S. C.[1]·Pinho, M. C.[2]·Leite, C. C.[1]
[1]Universidade de São Paulo, São Paulo, BRAZIL, [2]University of Texas Southwestern Medical Center, Dallas, TX.

Purpose
The purpose of this exhibit is to review and illustrate conventional and functional magnetic resonance imaging (MRI) findings after stereotactic radiosurgery (SRS) for metastatic brain tumors.
Materials & Methods
Review of imaging findings of metastatic brain tumors treated with SRS, using sample cases from a specialized tertiary oncologic hospital.
Results
Stereotactic radiosurgery for metastatic brain tumors: A) Clinical application, B) Biological effects, C) Conventional magnetic resonance imaging, D) Diffusion-weighted Imaging, E) Perfusion-weighted imaging, F) Permeability-weighted imaging, G) 1H-magnetic resonance spectroscopy.
Conclusion
Radiosurgery is a therapeutic modality of proven efficacy that has been applied increasingly in the management of metastatic brain tumors. The major teaching points of this exhibit are to review MRI findings after radiosurgery for metastatic brain tumors, and to present a strategy for imaging evaluation that potentially may aid in the differentiation of residual/recurrent tumor from radiation-induced lesions. Radiologists should be familiarized with these finding in order to provide more accurate follow-up results and to improve patient clinical outcome.

KEYWORDS: Metastases, Radiation therapy

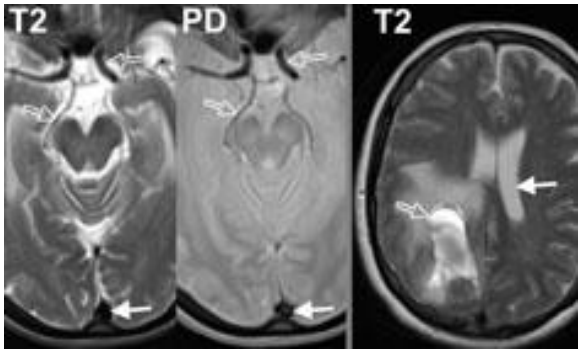
Two Common Image Appearances that Seem to Contradict MR-Physics

Fourgas, E.·Abele, T.·Rassner, U.
University of Utah
Salt Lake City, UT.

Purpose
Knowledge of MR-physics is important to understand findings on magnetic resonance (MR) imaging. However, occasionally appearances on MR images seem to contradict MR-physics: Lesions with higher signal on T2 fast spin-echo images than CSF and flow voids looking better on proton density (PD) than T2 images. The purpose of this presentation is to resolve these apparent contradictions.
Approach/Methods
Cystic brain lesions can have higher T2 signal than CSF despite water having the longest T2 time of all tissues. Flow voids look superior on proton density than T2-images, even though better flow voids should be seen on long TE sequences. A careful review of imaging parameters, detailed image appearance and MR-physics in respect to these phenomena was undertaken.
Findings/Discussion
Water has the longest T2 time (4-5 seconds at body temperature), but also the longest T1-time of all tissues. While most tissues fully recover with commonly used TR (4-5 seconds), water would need 20-25 seconds. Proteinaceous cysts will recover more longitudinal magnetization than CSF with commonly used long TR times and have more transverse magnetization after the 90 degree rf-pulse. Despite proteinaceous cysts having shorter T2 times than water, the more efficient T1-relaxation can overwhelm shorter T2 effects and result in higher T2 signal (T1 shine-through). This could be overcome by increasing TR or TE, however this would prolong the exam or produce a more myelographic appearance. Flow voids are said to be better with longer TEs (increased separation between the 90- and 180 rf-pulse). However, flow voids are more striking PD than T2 images despite a short TE. Region of interest measurements reveal that arterial flow voids are almost entirely devoid of signal on T2 and PD images (open arrows), while venous flow voids are darker on T2 than PD images (closed arrows), owing to the longer TE. However, short TE results in higher parenchymal signal and thus a larger signal difference between flow voids and parenchyma on PD compared to T2 images.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Summary/Conclusion
Lesion with higher T2 signal than CSF and flow voids looking better on proton density than T2 images do not contradict MR-physics. Understanding the underlying principles of these imaging findings can aid in clinical interpretation: Cysts with higher T2 signal than CSF must have T1 shortening. Flow voids are more robust on T2, however flow compromise will become apparent earlier on PD than T2 images.

MR Imaging in the Differential Diagnosis of Intra-Axial Cervico-Medullary Junction Lesions

Patro, S. N.·Torres, C.·Nguyen, T.
The Ottawa Hospital
Ottawa, ON, CANADA.

Purpose
The goal of this educational exhibit is to present different common and infrequent intra-axial pathologies of the cervico-medullary junction. We will discuss the characteristic MR imaging features and we will provide an imaging approach to the different cervico-medullary junction lesions.
Approach/Methods
We reviewed the imaging findings and clinical history of eight patients who presented with lesions at the cervico-medullary junction, in our Institution. All of these patients underwent routine imaging including T1-weighted images before and after gadolinium administration and T2-weighted images. The lesions and the differentiating features were discussed in detail.
Findings/Discussion
The cervico-medullary junction is a very important part of the central nervous system and the lesions affecting this area can present with varied neurologic symptoms including lower cranial nerve deficits. In this educational pictorial essay we will be discussing various intra-axial lesions involving the cervico-medullary junction including tumoral lesions such as brain stem glioma and ganglioglioma, infectious processes such as listeria rhombencephalitis and viral myelitis, inflammatory processes such as neuromyelitis optica and ADEM, demyelinating lesions such as multiple sclerosis and neurodegenerative disease such as amyotrophic lateral sclerosis. We also have included one patient who was referred from another Institution with marked enlargement and T2 hypersignal of the cervico-medullary junction mimicking a tumor. Before a cord biopsy was done, the images were reviewed carefully; subtle flow voids were noted on the dorsal surface of the cervicomedullary junction leading to the diagnosis of spinal DAVF which was confirmed with catheter angiogram. We also will discuss the characteristic imaging findings and differentiating features of each entity.
Summary/Conclusion
Different intra-axial pathologies can involve the cervico-medullary junction with varied clinical presentation. In combination with clinical and laboratory findings, MR imaging plays a very important role in differentiating and characterizing these lesions.

KEYWORDS: Glioma, Multiple sclerosis, ganglioglioma, ADEM, meyelitis

eEdE-50

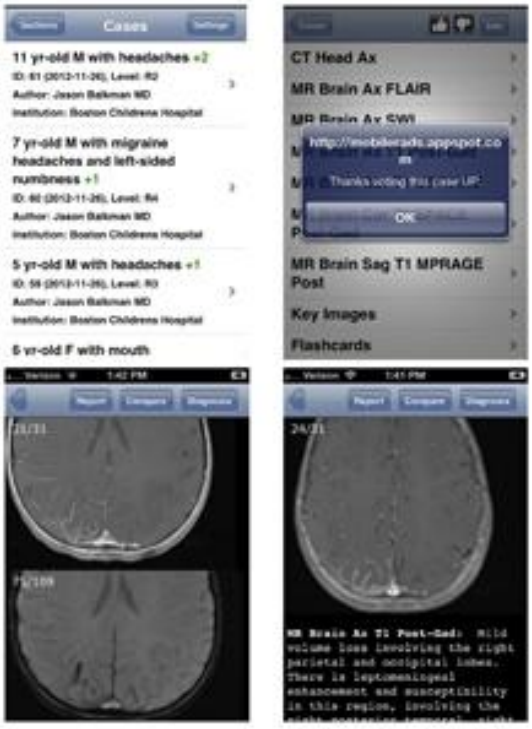
A Public and Scalable Neuroradiology Teaching File for Mobile Devices

Balkman, J. D.[1,2]·Prabhu, S. P.[2]·Belden, C. J.[1]
[1]Dartmouth-Hitchcock Medical Center, Hanover, NH,
[2]Boston Children's Hospital, Boston, MA.

Purpose
To develop an online neuroradiology case file for mobile devices that resembles the navigation capability of a PACS workstation. The mobile teaching file should be low-cost, universally accessible, connect to a real-time database, and have an intuitive and functional user interface.
Approach/Methods
The Eclipse open-source environment with Java software development kit (SDK) was used to develop frontend and backend software on a MacBook Pro computer. Local testing for handheld devices was performed using the XCode iOS simulator. The Google App Engine SDK plugin for Eclipse was utilized for deployment of the application to a unique and publicly available website hosted by Google, http://mobilerads.appspot.com. A Google Cloud SQL server was used to organize case information while Google Blobstore was used to host image data. Cases and image files were served to the end-user in a mobile-friendly format utilizing Java, jQuery and JavaScript programs, which provided the look and feel of a “native” handheld application. Navigation of the cases was evaluated on latest versions of both the iPad (2nd, 3rd, and 4th generations) and iPhone (4, 4S, 5) running iOS 6.
Findings/Discussion
A mobile application connected to a real-time case database was created with upfront costs of under 30 dollars per month. At the time of this writing, 26

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

neuroradiology teaching cases were added to the database. Each teaching file consisted of image stacks from one or more sequences, annotated key images with captions, diagnostic reports, a discussion section, and set of "flashcards" for self-quizzing. Cases were available online immediately after uploading. The application was compatible with the latest iPhone and iPad mobile devices. Download times with Wifi connection averaged 3 seconds for each sequence. Navigation of cases using finger gestures allowed image zoom, pan, and image stack scrolling. Users were able to vote cases up/down, search the case database by diagnosis, compare and navigate two sequences simultaneously, and read reports while viewing images.



Summary/Conclusion
Current technology affords the ability to create public, low-cost, and scalable teaching files for mobile devices connected to real-time databases. These applications give users a similar interactive experience to a PACS workstation, allowing image panning, zooming, and stack scrolling by way of finger gestures. Image rich mobile device "apps" as the one described above are well suited for neuroradiology, allowing the user to compare intricate anatomy across multiple sequences simultaneously, while providing annotated images and online teaching.

To Infinity and Beyond: Exploring the Future of Neuroradiology

Khan, M.·Hoeffner, E.·Srinivasan, A.
University of Michigan Health System
Ann Arbor, MI.

Purpose
The purpose of this exhibit is to discuss recent advances in neuroimaging and their associated clinical applications in an effort to paint a picture of the future of neuroradiology.
Approach/Methods
This exhibit is divided into two broad categories, CT and MRI, with focus on technical advances in each modality and their clinical applications. The exhibit will aim to briefly review some of the major emerging imaging techniques in these modalities, with straightforward explanations and the use of informative illustrations. Some examples of these emerging CT techniques include: dual energy CT, 4D CT perfusion analysis, adaptive and model-based iterative reconstruction, and phase-contrast CT. Examples of emerging MRI techniques that will be discussed include: parallel imaging, multiplexed echo planar imaging, advancements in perfusion imaging, diffusion tensor imaging, compressed sensing multi-spectral imaging, PET-MRI, and ultrahigh-field MRI (7.0 Tesla). Emphasis will be placed not only on the science behind these techniques, but the relevance to neuroimaging today. Where appropriate, prior published experiences with these new imaging techniques will be summarized and referenced.
Findings/Discussion
The variety of new imaging techniques in CT and MRI offer a pathway to improved diagnosis of subtle lesions by improving tissue characterization (in the case of ultrahigh-field MRI and phase-contrast CT), dramatically decreased image acquisition time (multiplexed echo planar imaging, parallel imaging), reduction of radiation dose (iterative reconstruction), and unique functional information (diffusion tensor imaging). These advances may not only provide valuable information and tangible benefit to the referring clinician and patient, but may expand the variety and appeal of the ever-growing field of neuroradiology.
Summary/Conclusion
The field of neuroradiology has progressed tremendously since the days of pneumoencephalography, and will continue to advance rapidly as newer imaging technologies emerge. This exhibit provides a concise and unified source of review of the advances in neuroimaging in an easily digestible format.

KEYWORDS: 4D CT, Dual-energy CT, compressed sensing

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

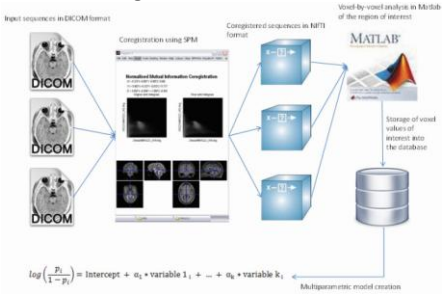
Image Coregistration: Quantitative Processing Framework for the Assessment of Brain Lesions

Huhdanpaa, H. T.·Hwang, D. H.·Cen, S.·Lerner, A.·Boyko, O. B.·Law, M.·Shiroishi, M. S.
University of Southern California
Los Angeles, CA.

Purpose
The quantitative, multiparametric assessment of brain lesions may require postprocessing steps which often consist of coregistering different parameters derived from MR imaging (MRI) sequences such as T1-weighted dynamic contrast-enhanced (DCE), T2*-weighted dynamic susceptibility contrast (DSC), and diffusion-weighted (DWI) and diffusion tensor (DTI) MRI, among others. This will be followed by analysis of the voxel values of the region of interest within the sequences and calculated parametric maps (ie., ADC, FA, permeability), and then deriving multiparametric models to help classify imaging data. For these approaches to scale to busy neuroradiology practices and to become more widely adopted among clinical neuroradiologists, there is a need for an intuitive quantitative processing framework which ideally may be constructed from commonly available and open-source components, and which will maximally automate the postprocessing steps. Additionally, such a framework should be generic and modular enough to adapt to different clinical and research questions without significant reworking.
Approach/Methods
One of the goals of the project is to construct a quantitative postprocessing framework with open source and commonly available software components as much as possible. With this goal in mind, Matlab, which is commonly available, was chosen for the actual postprocessing environment, and Statistical Parametric Mapping (SPM), which is open-source, was chosen for the coregistration portion of the framework. Matlab routines were designed and implemented to extract and concatenate the coregistration transforms, to take the coregistered MRI sequences as inputs to the process, allow the user to specify the region of interest (ROI), and then store the voxel values within the ROI to the database for further statistical analysis and multiparametric model creation (Figure 1). The functionality of the framework was validated using brain tumor MRI cases.



Findings/Discussion
The implementation of this quantitative postprocessing framework can enable a neuroradiologist to intuitively, without complex user interactions, create multiple parameters for each voxel, thus to facilitate in depth voxel-wise analysis. It also will reduce the postprocessing time to near real time.
Summary/Conclusion
This work supports the idea that common software components can be utilized to implement an intuitive real time quantitative postprocessing framework. It can result in improved scalability and hopefully increased adoption of the postprocessing steps needed to answer important neuroradiologic diagnostic questions.

Pitfalls in the Interpretation of Dynamic Contrast-Enhanced Cross-Sectional Imaging with Particular Attention to Perfusion Imaging

Patel, K. M.·Chen, J.
University of California San Diego
San Diego, CA.

Purpose
Contrast-enhanced cross-sectional imaging techniques (CT, MR angiography and perfusion) are used routinely in evaluation of neurovascular anatomy and brain functional and metabolic parameters. There are numerous pitfalls relating to these techniques that may lead to interpretive errors if the reader is not familiar with them.
Approach/Methods
Education Goals/Teaching Points - 1. Familiarize the reader with various potential pitfalls that may occur during interpretation of dynamically injected contrast-enhanced cross-sectional studies by using a case-based quiz format. 2. Provide the reader with practical strategies for accounting and avoiding these pitfalls including review of perfusion and angiographic source images. 3. Demonstrate how specific clinical data can significantly change initial interpretation and subsequent management (e.g., hyperperfusion therapy, chronic stenoses or occlusions, previous surgery). 4. Discuss basic principles and assumptions of perfusion imaging. 5. Discuss the effects of different postprocessing algorithms on accuracy of perfusion maps. 6. Discuss potential variability of perfusion maps based on postprocessing technique.
Findings/Discussion
Present key images from multiple clinical case examples such as: 1. Incorrect estimation of ischemic penumbra in setting of cerebral hyperperfusion. 2. Incorrect estimation of ischemic penumbra in setting of asymmetric inflow stenosis.

3. Suboptimal placement of region of interests (ROIs) and arterial input functions (AIFs). 4. Artifacts from retrograde flow such as retrograde venous perfusion in the setting of either functional or anatomical central venous stenosis.
Summary/Conclusion
Multiple potential pitfalls that may occur during interpretation of contrast-enhanced cross-sectional studies may be avoided by gaining better understanding of technical acquisition and postprocessing parameters, clinical information and review of source images.

eEdE-54

It's a Bird!⋯It's a Plane!⋯Oh Wait, It's Just Artifact: A Pictorial Review of the Most Commonly Encountered Artifacts in High-Field Strength MR Imaging of the Central Nervous System for Beginners

Zohrabian, V. M.·Zoltani, Z.
Thomas Jefferson University Hospital
Philadelphia, PA.

Purpose
MR imaging (MRI) is a powerful, safe and noninvasive tool, which has become widespread in neurologic examinations owing to excellent soft-tissue contrast and spatial resolution. Despite advances in imaging protocols and updated hardware and software packages, MRI remains vulnerable to a host of imaging artifacts given inherent properties of the patient being scanned, data inconsistencies, and hardware imperfections. Imaging artifacts may confound interpretation and mimic pathologies when not recognized. The purpose of this education exhibit is to allow recognition of the most commonly encountered artifacts in MR imaging of the CNS, and may be especially useful for trainees and those novice to the interpretation of neurologic imaging studies. Through a review of clinical images, we hope to alleviate misunderstandings that may lead to misdiagnoses in high-field strength MR imaging of the CNS.
Approach/Methods
Through a case-based, interactive format, we will highlight artifacts that are commonly seen with high-field strength MRI of the head, neck and spine. The types of artifacts discussed will include but not be limited to ghosting artifact secondary to motion, J-coupling in T2-weighted fast spin-echo imaging, flow-related artifacts as may be seen in large vessels and cerebrospinal fluid, magnetic susceptibility artifacts such as with axial diffusion-weighted echo planar imaging, metallic-related artifacts, inhomogeneous or incomplete fat saturation, and chemical shift artifacts. The examples presented will focus on the potential for radiologic misinterpretation in the presence of such artifacts. When available, the appearances of image artifacts on 1.5T MRI will be compared with 3T MRI, with an additional focus on recognizing the increased sensitivity to contrast enhancement of leptomeningeal and pachymeningeal vessels afforded by 3T MR imaging.
Findings/Discussion
Recognition of various MR imaging artifacts is needed to efficiently and accurately interpret clinical cases. Furthermore, with some working knowledge of the physical bases of artifacts, strategies can be implemented to lessen their severity, and thus, increase diagnostic certainty.
Summary/Conclusion
The quality of MRI may be limited by a variety of artifacts that may prove particularly problematic for beginner readers of neurologic imaging. A better understanding of such artifacts is necessary not only for the appropriate interpretation of cases, but also for the implementation of measures to optimize MR image quality.

KEYWORDS: Artifacts, MR imaging

eEdE-55

Perfusion Imaging Deconvolved: A Primer on Theory, Analysis, and Interpretation for the Neuroradiologist

Bansal, V.[1]·Kudo, K.[2]·Dehkharghani, S.[1]
[1]Emory University, Atlanta, GA, [2]Iwate Medical University, Morioka, JAPAN.

Purpose
Numerous techniques have been proposed to measure cerebral blood flow (CBF) and noninvasively probe tissue perfusion. Applications include stroke diagnosis and prognostication, tumor grading, and characterization of normal physiology. While the development of a readily accessible yet truly quantitative measure of CBF remains enigmatic, several semiquantitative techniques employing CT/MRI dynamic bolus passage with rapid imaging, adapted from classic indicator dilution theory, have shown promise in widespread applications. An extensive body of literature has highlighted the significant variability in computed perfusion across various methodologies and analysis schemes, and between competing third party vendor perfusion analysis systems. While the variability and potential instabilities inherent to such techniques may impact profoundly clinical decision-making, the fundamental theories governing these techniques remain generally under appreciated by practicing radiologists, limiting insight into specific advantages or comparative attributes of available systems. The primary motivation for this exhibit was development of a perfusion imaging primer to expand accessibility and appreciation of perfusion theory to a broader audience, specifically underscoring the theoretical features most relevant to practicing neuroradiologists. The primer will expound those features at the intersection of mathematics, engineering, physiology, and cerebrovascular disease, in a systematic and methodical framework designed for imaging clinicians, using a graphical and case-based format highlighting data acquisition, postprocessing, and

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

interpretation.
Approach/Methods
Using cases from our large local database and custom animations, we will explain the relevant physiology and graphically depict the theory underlying the computation of the most commonly encountered perfusion parameters. We will further demonstrate the effects of various postprocessing paradigms on final perfusion estimates, focusing on their potential clinical impact through sample cases and simulations.
Findings/Discussion
Noninvasive measurements of cerebral perfusion offer an invaluable probe of disease and normal physiology, and aid prognostication and treatment planning. This exhibit will focus on MR/CT-based perfusion methods utilizing exogenous nondiffusible tracers (NDT). The most commonly computed perfusion parameters include blood volume, blood flow, mean transit time, and T_{max}. The first three are related by the central volume theorem, and predicated upon a theoretically "instantaneous" bolus to a closed capillary system. Owing to the real-world bolus delay/dispersion inherent to the proximal IV injections of NDT, the tissue time-concentration curves observed in practice do not reflect tissue perfusion in any straightforward manner. To simulate the effects achieved from such a theoretically instantaneous bolus, many algorithms deconvolve an arterial input function (AIF) from the tissue-concentration curve, thus allowing recovery of the so-called tissue residue function, representing the tissue's response to such an impulse bolus. We will explain graphically the principles of convolution/deconvolution as it applies to perfusion imaging, as well as the physiologic significance of these common perfusion parameters. These techniques will be compared to simpler, nondeconvolution-based techniques, as well as to more complex parametric models of perfusion more recently gaining attention.
Summary/Conclusion
This perfusion imaging primer aims to provide neuroradiologists with critical insights related to perfusion imaging theory, acquisition, and postprocessing. Principles are presented by an illustrative and case-based exhibition of the scientific basis, with emphasis on practical clinical differences and limitations.

KEYWORDS: Brain perfusion, Deconvolution, primer

eEdE-56

Current Diagnostic Imaging of Carotid Artery Stenosis

Park, Y.·Nguyen, V.
Long Island Jewish Medical Center
New Hyde Park, NY.

Purpose
The purpose of this presentation is to provide a current multimodality review of carotid artery stenosis, its detection, calculation and characterization of the plaque morphology by ultrasound, computed tomography and magnetic resonance imaging. The diagnostic impact on the management of carotid artery stenosis will be examined. Concluding this presentation will be a focal refresher of the documentation of technique and recommended reporting for carotid artery stenosis.
Approach/Methods
This will be a case-based review of carotid artery disease characterization by ultrasound (US), computed tomography angiography (CTA), magnetic resonance angiography (MRA). Current literature review of the different stenosis percentage calculations and the impact on management will be discussed. We will discuss the methods used to assess the degree of internal carotid artery stenosis [e.g., North American Symptomatic Carotid Endarterectomy (NASCET) and European Carotid Surgery Trial (ECST)]. We will review additional findings in carotid disease, such as plaque ulceration and hemorrhage. Finally, we will compare current ICD-9 and the future ICD-10 report requirements for this disease evaluation. We will highlight the appropriate documentation of imaging technique and findings.
Findings/Discussion
Although historically conventional angiography is the gold standard with which noninvasive imaging (MRA, and CTA) are compared, its use has decreased with improved accuracy of noninvasive imaging. It now is utilized mainly in conjunction with revascularization in stent placement. Noninvasive imaging is now the preferred choice. Ultrasound is recommended in patients with moderate risk because of its availability and low cost but may overestimate the severity of stenosis. MR angiography or CTA are recommended when sonography is equivocal or indeterminate, particularly in symptomatic patients. MR angiography holds the advantage of lack of radiation whereas CTA is accessible with few contraindications. Conventional angiography is used for discordant results or if there is preference for limited contrast in cases with renal dysfunction. Accurate quantification of stenosis severity has ramifications in steering medical, endovascular or surgical treatment. Stenosis can be calculated with different methods, but may result in different percent stenosis for the same patient. Thus, it is particularly important to state the method used. The NASCET and ECST are the primary methods used to grade the stenosis, and will be discussed. We will discuss the use of imaging in characterization of plaque morphology. A clear and succinct report in compliance with ICD-10 will maximize reimbursements that the physician and hospital receives, as well as help protect against Medicare's recovery audit contractor (RAC).
Summary/Conclusion
As neuroradiologists we play a critical role in providing an accurate evaluation and description of the severity of carotid artery stenosis. Our reports are central to the management of patients as well as reimbursement ramifications.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eEdE-57

Clinical Application of High-Resolution MR Intracranial Vessel Wall Imaging

Choi, J.·Kim, S.·Han, M.·Im, N.
Ajou Medical Center
Suwon, KOREA, REPUBLIC OF.

Purpose
Compared with conventional MR imaging (MRI) and MR angiography (MRA), high-resolution (HR) MR intracranial vessel wall imaging can acquire high quality images that could depict intracranial arterial wall. High-resolution MR intracranial vessel wall imaging could demonstrate the various intracranial conditions such as stable or unstable atherosclerotic stenosis, vasculitis, dissection and perforating artery disease. In this presentation, we will review the basics, protocols and clinical application of the HR contrast-enhanced MR intracranial vessel wall imaging.
Approach/Methods
**Basic and protocols for HR contrast-enhanced MR intracranial vessel wall imaging. HR 2D T1WI, T2WI, PDWI, 3D black blood T1WI, 3D black blood T1WI with contrast enhancement and 3D FLAIR VISTA
Findings/Discussion
**Unstable atherosclerotic stenosis. Eccentric intracranial artery stenosis is related to atherosclerotic disease and the enhancement that has been correlated with plaque inflammation and instability may represent unstable plaque. Expensive remodeling also was seen more frequently in patients with unstable plaque. **Stable atherosclerotic occlusion. Constrictive remodeling was seen more frequently in patients with stable stenosis, whereas expansive remodeling was observed more frequently in patients with unstable vascular disease. Constrictive remodeling, while playing a role in accelerating the narrowing of lumen, was associated with stable features. **Vasculitis. In contrast to the pattern seen in patients with atherosclerotic stenosis, patient with vasculitis showed a smooth, diffuse, concentric pattern of enhancement. **Intracranial artery dissection. Intracranial dissection had a similar pattern to atherosclerosis, including eccentric wall thickening with enhancement. High-resolution MRI could demonstrate dissecting flap and vascular ectasia at the segment of the arterial dissection. Another distinguishing feature is bright wall component on nonenhanced T1 and FLAIR sequences (indicating methemoglobin in the arterial wall), as well as visualization of a false lumen. **Normal-appearing angiography in patients with brain stem infarction on 3D TOF MRA. Occasionally, we can see the lenticulostriatal or brain stem infarction without any abnormality on TOF MRA by virtue of expensive remodeling or too small vessel wall disease. High-resolution MRI could demonstrate wall enhancement or thickening in some patients with these infarctions. **The usefulness of 3D FLAIR VISTA image for intracranial vessel wall imaging. 3D FLAIR VISTA MRI that can acquire high quality images is very sensitive for hemorrhage or fluid with high protein contents. On contrast-enhanced T1-weighted image, intraluminal flow stasis due to severe stenosis or dissection could be demonstrated as intraluminal high signal intensity that could cause misunderstanding of enhanced active plaque. 3D FLAIR VISTA MRI could be helpful to differentiate intravascular stagnant blood from plaque enhancement. 3D FLAIR VISTA MRI is also helpful to detect intramural hematoma or intraplaque hemorrhage.
Summary/Conclusion
High-resolution MR intracranial vessel wall image could depict intracranial vessel wall and its pathology in ischemic stroke and TIA patients. High-resolution multisequences have the potential to characterize the pathology in the intracranial artery and may be a useful modality for evaluating the degree of stenosis. Also, this sequence makes it possible to depict some pathology in the vessel wall without conventional angiographic abnormality.

eEdE-58

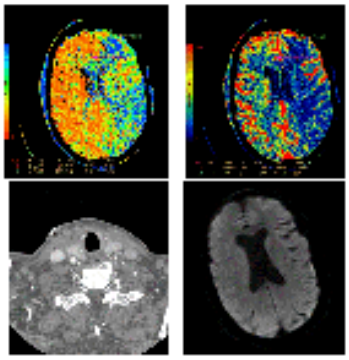
Stroke Mimics Imaging Atlas: Pearls and Pitfalls in Interpretation of Brain CT Perfusion Studies

Tamrazi, B.·Yuh, E.
University of California San Francisco
San Francisco, CA.

Purpose
In this educational exhibit, we demonstrate CT perfusion correlates of both common and unusual mimics of acute stroke. Prior studies have demonstrated that approximately 20% of patients who receive thrombolysis for acute ischemia ultimately are found to have an alternate clinical diagnosis. It is important for neuroradiologists to be aware of perfusion imaging correlates of these alternate diagnoses, as well as normal variants and anomalies in perfusion imaging studies. We provide an organized review of pearls and pitfalls in the interpretation of brain perfusion studies, employing numerous examples from our institution. The discussion also has relevance to MRI cerebral perfusion maps obtained using dynamic susceptibility contrast or arterial spin labeling perfusion imaging.
Approach/Methods
Using cases collected from clinical practice, we demonstrate brain perfusion normal variants and both common and uncommon correlates of mimics of acute ischemia and stroke. Cases are presented as unknowns with clinical history and exam, followed by initial neuroradiologist interpretation, and concluding with the final clinical diagnosis and follow-up information.
Findings/Discussion
Neuroradiologists can play a decisive role in the

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

management and treatment of acute ischemia and stroke through prompt, accurate interpretation of brain perfusion studies. Familiarity with limitations and pitfalls associated with these studies can prevent unnecessary thrombolytic therapy in cases of clinical and imaging mimics of acute stroke. Cases to be discussed include perfusion alterations in seizure and postictal state, chronic high-grade carotid stenosis resulting in chronic oligemia (Figure 1), post-hemicraniectomy state, immediate post-carotid endarterectomy state, subtle primary brain tumor, transient ischemic attack, migraine headaches, and luxury perfusion in the setting of subacute infarct. Giant internal carotid artery aneurysms and other nonocclusive hemodynamically significant lesions that result in delayed flow to major vascular territories, and the impact of different perfusion postprocessing algorithms on perfusion maps in these cases, also will be discussed.



Summary/Conclusion

Brain perfusion studies are an important component of the imaging evaluation of acute ischemia and stroke. We review key examples of brain perfusion studies that mimic acute ischemia and stroke. Familiarity with these common pitfalls and variants in brain perfusion imaging can aid neuroradiologists in making prompt, decisive contributions to clinical management in suspected acute ischemia and stroke.

Suboptimal Contrast-Enhanced Head and Neck MR Angiography Due to Venous Reflux: Analysis of Causative Factors

Lee, E.·Shin, D.
Dongguk University Ilsan Hospital
Goyang-City, KOREA, REPUBLIC OF.

Purpose

Contrast-enhanced head and neck MR angiography (MRA) may be degraded by venous stasis or reflux of contrast into the jugular veins. The purpose of this study was to analyze the causative factors of venous stasis or reflux on contrast-enhanced head and neck MRA.

Approach/Methods

We retrospectively reviewed 300 consecutive patients who underwent contrast-enhanced head and neck MRA (right injection-150 patients, and left injection-150 patients). We also reviewed the age, sex, body mass index (BMI), history of hypertension, and history of diabetes mellitus (DM) of all patients. We measured the shortest width of left or right brachiocephalic vein (BCV), the diameter of aortic arch, the distance between sternum and vertebral body. The relationship between these factors and the venous stasis or reflux was analyzed.

Findings/Discussion

In all 300 patients, 45 (15%) patients showed venous stasis or reflux. Among the 45 patients, patients with left-arm injection were 30 and patients with right-arm injection were 15. And the difference was statistically significant (P = .015). Venous reflux into the jugular vein or cervical vein also was more severe in patients with left-arm injection. The mean age and the male-to-female ratio of patients with venous stasis or reflux was significantly higher than the patients without venous stasis or reflux. The BMI, history of hypertension and history of DM did not significantly differ. In 150 patients with left-arm injection, 30 (20%) patients had venous stasis or reflux. The mean shortest width of left BCV of the 30 patients with venous stasis or reflux was significantly narrower than that without venous stasis or reflux group (2.96 ± 0.29 mm vs. 4.80 ± 0.21 mm; P = .0001). After we adjusted for sex and age in the logistic regression model, the shortest width of left BCV still was associated significantly with venous stasis or reflux. There was no significant difference in the mean diameter of aortic arch (P = .21), and the mean shortest anteroposterior distance from the sternum to the vertebral body (P = .14) between the two groups. In 150 patients with right-arm injection, all variables did not differ significantly.

Summary/Conclusion

Compression of the left BCV can lead to venous stasis or reflux. To acquire an optimal image on contrast-enhanced head and neck MRA, left-arm injection should be avoided especially in the elderly patients.

KEYWORDS: MR angiography, Carotid angiography

eEdE-60

Brain Cortical Lesions: Ischemia and Beyond

Adapa, P.·White, M. L.·Helvey, J. T.·Keiper, M. D.
University of Nebraska Medical Center
Omaha, NE.

Purpose

Ischemic injury is the most common and a well recognized etiology for cortical abnormalities detected with brain MRI. However, nonischemic etiologies can mimic the appearance of cortical ischemia. Pattern recognition is

critical in arriving at a diagnosis to help the clinical teams in their management plans. In this exhibit, we present a clinical and imaging review of the various ischemic and nonischemic cortical lesions.
Approach/Methods
A review of our PACS database and personal teaching files was performed by the authors. Representative cases of various cortical lesions were selected. Conventional MRI features and additionally T1 dynamic enhancement, dynamic susceptibility enhancement, diffusion imaging and spectroscopy features of these cortical lesions will be reviewed. Emphasis is made on lesions with restricted diffusion abnormalities which have the greatest confounding appearance with ischemic lesions.
Findings/Discussion
We review the MRI findings of focal ischemia and the varying degrees of diffuse hypoxic-ischemia injury. Then, we discuss the imaging features of other cortical lesions including but not limited to viral encephalitis, Creutzfeldt-Jakob disease (CJD), glioma with cortical infiltration, mitochondrial diseases, leukemic cortical infiltration, hyperammonemia, hypoglycemia, electrolyte abnormalities and postictal changes. Symmetry and extent of cortical involvement on MRI and evaluation of perirolandic or watershed zone cortical involvement are two of the important imaging characteristics to differentiate ischemic versus nonischemic lesions. Other patterns of involvement, like temporal lobe involvement in herpes encephalitis or pontine changes associated with osmotic demyelination, can suggest an alternate diagnosis. Laboratory diagnostic information, including microbiologic and CSF analysis can sometimes be the key to differentiate cases of encephalitis, CJD, metabolic and electrolyte abnormalities. However, brain or muscle biopsy may be needed for mitochondrial diseases. Advanced imaging studies including T1 and T2* dynamic contrast enhancement, diffusion imaging and MR spectroscopy (as in identifying elevated lactic acid level in MELAS) can help differentiate these various cortical lesions and guide the clinician for appropriate work up to arrive at the correct diagnosis.
Summary/Conclusion
Through this educational exhibit, we provide a pictorial essay of the various ischemic and nonischemic cortical lesions. We explain the utility of using certain advanced imaging techniques, most importantly diffusion imaging, in differentiating these lesions to guide the clinicians appropriately for proper clinical management.

KEYWORDS: Cortical involvement, Ischemia, restricted diffusion, nonischemic lesions

eEdE-61

Head-to-Head Comparisons between MR Perfusion (Arterial Spin Labeling and Dynamic Susceptibility Contrast) and CT Perfusion in Seizures and Strokes

Baruah, D.·Raslau, F.·Gupta, S.·Klein, A.·Ulmer, J.
Medical College of Wisconsin and Affiliated Hospitals
Wauwatosa, WI.

Purpose
A variety of perfusion techniques have become commercially available, including MR perfusion methods such as arterial spin labeling (ASL) and dynamic susceptibility contrast (DSC) as well as CT perfusion (CTP). Due to differences in technique, software algorithm, color palette, and color scale, perfusion maps in the same patient may yield difference results. A head-to-head comparison between these perfusion techniques can reveal relative advantages and disadvantages, which can be used to optimize imaging strategies for different clinical needs.
Approach/Methods
The similarities and differences are reviewed between ASL, DSC, and CTP in terms of basic physics and technique. Then an array of head-to-head comparisons is illustrated in both seizure and stroke workups. Their relative advantages and disadvantages are identified, and suggestions are offered for optimizing the choice of perfusion technique for specific clinical contexts.
Summary/Conclusion
In seizures, ASL is superior for identifying peri-ictal activity and for differentiating stroke-mimicking seizures. In strokes, ASL has the highest negative predictive value. Consequently, ASL is the optimal imaging strategy when the clinical question requires the exclusion of perfusion abnormalities.

KEYWORDS: Arterial spin labeling, Dynamic susceptibility contrast-enhanced, computed tomography perfusion, stroke, seizure

eEdE-62

Why Is the Area Hyperperfused on CT Perfusion?

Patro, S. N.·Nguyen, T.·Torres, C.·Lum, C.·Chakraborty, S.
The Ottawa Hospital
Ottawa, ON, CANADA.

Purpose
Perfusion CT frequently is used in patients with ischemic stroke for assessment of core infarct and ischemic penumbra. However, it is not infrequent to see areas of increased CBV in the workup of patients with suspected stroke. The aim of this pictorial essay is to present and discuss different causes of increased CBV or CBF seen with CT perfusion in the workup of patients with acute or chronic cerebral ischemia.
Approach/Methods

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

We reviewed clinical and imaging data from eight patients who underwent CT perfusion for acute or chronic cerebral ischemia who had areas of increased CBV or CBF.
Findings/Discussion
Causes of increased CBV can be classified as global or local. Global causes could be due to acetazolamide challenge. In patients with chronic cerebral ischemia related to underlying stenotic lesion, the acetazolamide challenge test is helpful in distinguishing areas with decreased CVR (tissue under hemodynamic stress) from areas with preserved CVR (tissue with reduced metabolic demand). Acetazolamide challenge fails to cause increased CBF and CBV in areas with decreased CVR and thus helps in selecting patients for revascularization. Local increase in CBV and CBF could be secondary to various causes. Luxury perfusion is a condition that can be encountered in patients after recanalization following acute ischemic stroke. There will be increased CBF and CBV in the infarcted tissue which predisposes it for hemorrhagic transformation. This also can be encountered following carotid endarterectomy and predicts the chances of postrevascularization intracranial bleed. An accidental intra-arterial injection of CT contrast into the brachial artery can cause focal rise of cerebral blood flow and volume. Cerebral blood flow and CBV also are markedly elevated within the AVM nidus and in the AVF, reflecting high vascularity; however, the perinidal/perifistula areas could demonstrate low CBV and CBF, suggesting ischemia. Perfusion imaging could differentiate focal seizures from ischemic stroke by demonstrating localized hypermic state in patients with seizure. High grade tumors like glioblastoma multiforme are inherently associated with increased perfusion of the tumor tissue secondary to underlying increased neoangiogenesis.
Summary/Conclusion
Clinical examination and close serial examination of the data volumes and of the dynamic CTangiogram often will provide clues to the right diagnosis when an area of increased perfusion is present.

KEYWORDS: CT perfusion, Stroke, tumor, seizure

eEdE-63

Challenges and Controversies of CT Perfusion in Acute Stroke

Vagal, A. S.·Khatri, P.
University of Cincinnati Medical Center
Cincinnati, OH.

Purpose
The purpose of this exhibit is to review the technical and pathophysiologic challenges of CT perfusion (CTP) and to assess existing literature for evidence-based medicine for use of CTP in acute stroke.
Approach/Methods
The exhibit will be divided into four main categories as follows: 1. Discussion of imaging biomarkers of patient outcome in acute stroke. 2. Sources of variability of CTP technique: patient, postprocessing algorithms, acquisition. 3. Thresholds used in the analysis of CTP: infarct core versus penumbral volume, penumbra versus benign oligemia, gray matter versus white matter thresholds. 4. Evidence-based guidelines for use of CTP in making acute stroke treatment decisions.
Findings/Discussion
Even after more than a decade of perfusion imaging, diagnostic and therapeutic efficacy of perfusion is an area of controversy and vigorous debate. To date, all published randomized controlled trials have used MR-based multimodal imaging for the thrombolytic treatment selection. No clinical trials have been conducted using CT-based multimodal imaging and currently evidence is lacking on the efficacy of CT perfusion in making acute stroke treatment decisions. Yet, due to wide spread accessibility of CT scanners, CTP is being rapidly assimilated into routine clinical practice of stroke evaluation and treatment.
Summary/Conclusion
Increasing utilization of CTP in acute stroke may be creating a paradigm shift and it is pertinent for the practicing neuroradiologist to be aware of the current controversies and challenges of CT perfusion.

KEYWORDS: Actue stroke, Brain perfusion

eEdE-64

Multimodal Approach of Intracranial Hypotension Syndrome: Pitfalls in Clinical Manifestations, Imaging Findings and Treatments

Pinzon, O.·Moritani, T.·Lai, L.·Capizzano, A.
University of Iowa Hospitals and Clinics
Iowa City, IA.

Purpose
To demonstrate multimodal imaging findings of intracranial hypotension syndrome correlated with clinical manifestations and post-treatment outcome. To discuss clinical and imaging pitfalls using cases with misdiagnosis leading to inappropriate or delayed management.
Approach/Methods
We reviewed 58 patients with intracranial hypotension syndrome with various clinical manifestations (postural headache, hearing complaints, vertigo, 6^{th} nerve palsy, facial numbness, seizure, hypersomnia, altered mental status and frontotemporal brain sagging syndrome). Imaging modalities included brain CT/MRI, total spine MRI, CT/MR myelography, and radioisotopic CSF leak study. Clinical management included bed rest, increased oral intake of fluids, caffeine, glucocorticoids, intrathecal saline infusion, lumbar epidural blood patch, epidural blood patch targeted to the leak level (cervical/thoracic) based on CT myelogram findings, and surgical ligation.
Findings/Discussion
The variety of symptoms is explained by the Monro-Kellie

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

doctrine: the sum of brain, CSF, and intracranial blood volumes remain constant. Compensatory mechanisms, such as venous engorgement, take place during CSF hypovolemia. Brain sagging can place traction on cranial nerves or cause subdural hematomas by tearing bridging dural veins. Severe brain sagging can cause acute altered mental status, hypersomnia or cognitive impairment. In most cases of intracranial hypotension, defined MRI criteria were found: pachymeningeal enhancement, subdural fluid collections, venous and pituitary engorgement, basal cistern effacement, brain and brainstem sagging and tonsillar ectopia. However, normal MRI did not exclude the diagnosis of intracranial hypotension. Radionuclide cisternogram was more sensitive but less specific compared to CT myelography. Dynamic CT myelography could determine location and extension of CSF leak, thus guiding epidural blood patch. However, in many typical intracranial hypotension cases, leak studies only showed multiple meningeal cysts without evidence of CSF leak, and patients only temporarily improved after multiple blood patches. Lumbar intrathecal infusion with normal saline can be used to temporarily restore CSF volume in patients with consciousness alteration requiring emergent treatment. These illustrative cases demonstrate the spectrum of pitfalls encountered in the diagnosis and treatment of intracranial hypotension. Potential pitfalls include: 1) clinically misdiagnosed as migraine; cervical radiculopathy; transient ischemic attack; subdural hematomas; subarachnoid hemorrhage; meningitis 2) misdiagnosed as Chiari I malformation on MRI treated with decompression surgery and delayed appropriate treatment (blood patch and surgical ligation) causing intracranial hypertension 3) intracranial hypertension associated with pregnancy leading to CSF leak causing intracranial hypotension, 4) Intraspinal CSF leak after lumbar puncture misdiagnosed as epidural abscess in an infant resulting in unnecessary surgery, 5) clinically misdiagnosed as fronto-temporal dementia which was turned to be “frontotemporal brain sagging syndrome” (autopsy was performed in one case and was negative for primary neurodegeneration), 6) CSF leak due to osteophytes, 7) intracranial hypotension related to pseudomeningocele, 8) complicated with cerebral venous sinus thrombosis, 9) C1-C2 retrospinal fluid collection mistaken for actual site of CSF leakage.

Summary/Conclusion

We demonstrate multimodality imaging findings and discuss the pathophysiology of intracranial hypotension syndrome with various clinical manifestations and post-treatment outcome. We illustrate pitfalls using the cases with misdiagnosis leading to inappropriate or delayed management emphasizing the role of neuroradiologists in diagnosing and treating this important condition.

KEYWORDS: Intracranial hypotension, MR imaging, myelogram

eEdE-65

Would You Know It If It Hit You in the Face? Exploring the Radiological Link Between Facial Fractures and Intracranial Hemorrhage

Pan, Q.[1]·Holstad, J.[2]·Byrns, K.[2]·Penna, K.[2]·Lev, S.[2]
[1]American University of the Caribbean, Saint Martin, SAINT MARTIN, [2]Nassau University Medical Center, East Meadow, NY.

Purpose

We investigate maxillofacial fractures and associated intracranial hemorrhages with the intent to enhance the radiologist’s search pattern.

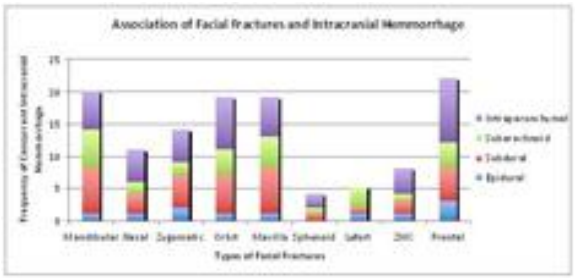
Approach/Methods

Trauma cases with concurrent imaging of the face and head were compiled from both our oral maxillofacial surgery clinics and our Level I trauma center ED. Patients with both traumatic maxillofacial injury and intracranial hemorrhage were categorized by mechanism of injury, age, gender, and sub-type of fracture or bleed. Isolated fractures considered were mandible, nasal, zygomatic, orbital, maxillary and frontal and fracture patterns were Lefort and zygomaticofacial complex. Intracranial hemorrhages were epidural, subdural, subarachnoid or intraparenchymal. We demonstrate illustrative cases and include literature highlights noting associations between traumatic maxillofacial injuries and intracranial hemorrhage.

Findings/Discussion

The facial skeleton, with its horizontal and vertical buttresses, may absorb significant energy during head trauma. When this capacity is surpassed, deleterious forces can be transmitted intracranially. There is immense variability (5.4 to 86%). in the literature concerning reported rates of concurrent maxillofacial fractures and intracranial hemorrhage. If we include only individuals with both head and maxillofacial CT exams, our original clinic list of 1682 patients is reduced to 131, while the ED list of 293 is narrowed to 139. Of the 270 total, 29 (10.7%) demonstrated at least one facial fracture with any intracranial hemorrhage. Mechanisms of injury include MVA, fall, assault, pedestrian struck and nonspecified trauma. Virtually all possible combinations of fracture and hemorrhage type were observed, though some trends were evident. Fractures involving the frontal bone revealed the strongest association with intraparenchymal hemorrhage. This observation is strongly supported and reflects the proximity of the frontal bone to the underlying brain. Lefort fractures demonstrated the strongest association with subarachnoid hemorrhage. Fractures of the sphenoid bone, involving the skull base, also had a relatively increased bleed association, reflecting the high energy forces involved.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Summary/Conclusion
In the emergent setting it is important for radiologists, surgeons, and emergency physicians to be cognizant of the propensity of facial fractures and intracranial hemorrhages to simultaneously occur. A clearer understanding of the patterns of facial injuries will assist both the on-call radiologist's search pattern and care provider's management. Several trends emerge, particularly highlighting the deleterious nature of frontal and Lefort-type fractures. Although the statistical utility of this review is limited by sample size and selection methods, the patterns observed fall within the aforementioned broad range of published data and presents new avenues for exploring these associations.

KEYWORDS: Traumatic brain injury, Craniofacial findings

eEdE-66

Head Trauma: The Role of Imaging and What the Radiologist Needs to Know

Khorrami-Arani, N.[1]·Liang, T.[2]·Nicolaou, S.[1]
[1]Vancouver General Hospital, Vancouver, BC, CANADA,
[2]University of British Columbia, Vancouver, BC, CANADA.

Purpose
The etiologies of head trauma usually vary with the patient's age; in the elderly population, accidental falls are the most common causes, whereas in younger patients and children, motor vehicle collisions and abuse are common causes respectively. Regardless, traumatic brain injury (TBI) from post head trauma is a leading cause of mortality and morbidity in the world's population and it has been estimated that approximately 2% of the entire population currently lives with disabilities caused by TBI, and over 500,000 emergency department visits annually are accounted for by head trauma. Thus, it is important for the radiologist to rapidly and accurately diagnose the TBI and be aware of the potential complications. The purpose of this exhibit is to review the pathophysiology of these injuries, discuss the role of imaging with emphasis on the roles of MDCT and MRI, and review the spectrum and classification of injuries.
Approach/Methods
A retrospective review of head trauma cases at our institution will be conducted for imaging examples to demonstrate the spectrum of these injuries.
Findings/Discussion
This education exhibit will review the epidemiology, anatomy, pathophysiology and mechanism of injury, and parameters for clinical assessment of head trauma. The spectrum of injuries post head trauma including epidural and subdural hematomas, shear injuries, subarachnoid hemorrhage, parenchymal and skull base injuries will be reviewed and imaging examples as well as characteristic imaging findings of each will be demonstrated and discussed. The role of imaging and a review of imaging modalities available for head trauma including , MDCT, CTA, MRI will be reviewed. Emphasis on the role of MDCT will focus on the utility of reformats, the significance in the size of the midline shift, the swirl sign, role of CTA and CTV in evaluating vascular injuries, the ability to demonstrate perfused blood volume imaging and perfusion with emphasis on the traumatic penumbra. The clinical significance of these findings on MDCT will be reviewed. Emphasis on the role of MRI will focus on the new techniques available for head trauma imaging including, but not limited to spectroscopy, diffusion tensor imaging, susceptibility imaging and MRI perfusion. Finally, an imaging and management algorithm for head trauma will be proposed and reviewed to help aid the radiologist and trauma team act quickly and effectively.
Summary/Conclusion
Head trauma presents with a unique spectrum of injuries and characteristic imaging findings that are important for the radiologist to quickly recognize as it can have significant implications on prognosis and management. These injuries and their imaging examples have been reviewed in this exhibit. MDCT and MRI with new techniques available for imaging of head trauma and TBI are extremely useful and have been reviewed here. A useful algorithm for imaging and management of head trauma has been proposed, this algorithm will allow the radiologist to efficiently and successfully decide management and can be easily adapted to the radiologist's daily practice.

KEYWORDS: TBI, head trauma

eEdE-67

The Dynamic Appearance of Intracranial Hemorrhage on MR Imaging and the Physics Behind It

LoStracco, T. A.·Shrier, D. A.·Meyers, S. P.
University of Rochester
Henrietta, NY.

Purpose
Characterization of the MRI features of intracranial hemorrhage can be important for the diagnosis and treatment of various pathologic disorders. The purpose of this exhibit is to illustrate the various configurations and locations of intracranial hemorrhages, as well as the sequential MRI signal changes over time, while describing the basic physical principles behind the evolution of a hemorrhage. This will help provide a deeper

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

understanding of these concepts.
Approach/Methods
Provide a brief summary of the biochemistry behind the evolution of hemorrhage and how these processes are exploited by MR physics to provide distinct imaging characteristics. This will be followed by numerous examples of high quality images of different types of intracranial hemorrhage, as well as all different stages of hemorrhage, ranging from hyperacute to chronic. These examples then will be correlated with the physical principles that were summarized previously.
Findings/Discussion
Often we learn about the evolution of intracranial hemorrhage through memorization of how each stage appears on each sequence. However, by understanding these principles at the microscopic level, one can develop a more profound understanding of how and why hemorrhage has the appearance it does. This will help provide more clear and confident interpretation of head MRs performed for intracranial hemorrhage.
Summary/Conclusion
It is easy to resort to memorization in order to understand a process as complex as evolution of intracranial hemorrhage. However, this is unnecessary if one has a working understanding of the biochemical and physical processes that are occurring.

KEYWORDS: Hemorrhage, MR imaging brain

eEdE-68

Be Prepared: The Spectrum of Neuroradiologic Emergencies of the Brain - A Primer for the On-Call Radiology Resident

Agrawal, J. P.·Lev, S.
Nassau University Medical Center
East Meadow, NY.

Purpose
Our educational exhibit aims to increase awareness and diagnosis of neuroradiologic emergencies of the brain. The interactive case-based discussion emphasizes common and unusual situations encountered on call. The viewer will discern subtle findings and consider more obscure diagnoses. Imaging pearls and take-home points are highlighted.
Approach/Methods
We present cases from our Level I Trauma and designated stroke center occurring during the past five years. Imaging modalities include CT, CTA/CTV, MRI, and MRA/MRV. We categorize emergencies by location and etiology. We also discuss the importance of mechanisms of injury. Each clinical scenario is followed by questions regarding the radiologic workup.
Findings/Discussion
Vascular emergencies can be ischemic, hemorrhagic, or both. Acute ischemic stroke necessitates prompt and accurate radiologic assessment. We ask the viewer to detect early subtle signs that can be missed. Pediatric stroke poses a unique challenge. It presents with unconventional symptoms and is due to varying etiologies. Without high suspicion, delays in stroke team activation may occur. Conditions that mimic stroke also must be considered. We present several cases of stroke mimickers, such as a glioblastoma multiforme that was misinterpreted as an infarct. Intracranial hemorrhage can be categorized by etiology (traumatic or nontraumatic) and location (intraparenchymal or extra-axial). Diffuse axonal injury results from rotational acceleration forces, accounting for lesion distribution. For contusions, the resident should evaluate for coup and contrecoup injuries. Mass effect and cisternal effacement must be communicated urgently. Subdural hemorrhages (SDH) result from low pressure venous bleeding. Intracranial brain motion may produce contralateral insult. Coronal reformats are useful in evaluating subtemporal, convexity, and tentorial hematomas. Low density areas within a heterogeneous SDH may represent unclotted blood. Epidural hemorrhages can not only be arterial but also, less commonly, venous, secondary to tears of the torcula or transverse sinus. Consider nonaccidental trauma in the pediatric population with extra-axial hemorrhages of varying ages. Subarachnoid hemorrhage (SAH) has many causes. Perimesencephalic nonaneurysmal SAH has a specific pattern and a benign course. Rarely, a ruptured aneurysm may present with intraparenchymal hemorrhage alone. Vascular injury is especially suspect with high velocity and rotational motions (MVA and athletic). Injury to vascular structures can be intracranial or extracranial and can produce pseudoaneurysms, A-V fistulas, and carotid dissections/occlusions. Assess for depressed calvarial, sphenoid (associated with carotid-cavernous fistulas), and petrous (carotid canal) fractures. Cervical fractures may produce vertebral injury. Nontraumatic vascular emergencies include intracranial hypertension/hypotension and vasculitides. Drug/toxin induced CNS injuries require a high index of suspicion. Posterior reversible encephalopathy syndrome is a rare condition that can be easily overlooked and requires prompt identification to prevent permanent damage. CNS infections differ in immunocompetent and immunocompromised individuals and can be categorized by location and pattern: extra-axial, ring-enhancing, temporal lobe, basal ganglia, and white matter lesions. Tumors, even benign ones, can be acutely life-threatening. We show an unusual case of a large colloid cyst, producing impending brain herniation secondary to hydrocephalus.
Summary/Conclusion
Neuroradiologic emergencies comprise a diverse array of conditions. The interpreting radiologist can actively participate in patient management with appropriate imaging recommendations, prompt diagnosis, and timely communication.

KEYWORDS: Emergencies, Educational, resident

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eEdE-69

Opening Pandora's Box? An Overview of Surgical Interventions on the Cranial Vault for the Radiologist

MacAdam, B. D.·Ambalathunkal, E.·Beecher, J.·Lev, S.·Lev, S.
Nassau University Medical Center
East Meadow, NY.

Purpose
We aim to provide an overview of the evaluation of the postoperative head. Using our experience with craniotomy, craniectomy, and cranioplasty at our institution, we discuss the indications, procedures, postoperative findings, and complications. We also relay surgical and pathophysiologic insights, focusing on what the neurosurgeon and radiologist need to know.
Approach/Methods
A list of all trauma patients undergoing craniotomy, craniectomy, or cranioplasty at our level I trauma center from January 2011 to present was obtained from the Department of Neurosurgery. Imaging was performed using a 320-slice CT scanner and reviewed by a board certified neuroradiologist. Only cases with both pre and postoperative imaging were included. The numbers of each type of procedure as well as complications and their temporal course were based on the imaging review in concert with clinical data. A review of the current neurosurgery and radiology literature regarding indications, techniques and complications was performed and summarized.
Findings/Discussion
The noncontrast head CT is the workhorse of pre and postoperative neurosurgical imaging. The radiologist must be aware of normal postoperative findings in order to quickly differentiate signs which may indicate potentially severe complications. Of the 38 cases ultimately included for review, there were 17 craniotomies, 18 craniectomies, and 2 cranioplasties. Three of the patients who initially underwent craniectomy required cranioplasty at a later date. We found a much higher number of complications following craniectomy (70.5% of cases) than either craniotomy (16.7%) or cranioplasty (0%). This ordering correlates to numerous reports in the literature. Our discussion includes a brief review of the relevant anatomy along with an overview of current and historical surgical perspectives.We highlight the various indications for neurosurgical intervention, including extra-axial and intraparenchymal hemorrhages, cerebral edema, and depressed skull fractures. The normal postoperative findings unique to each procedure are discussed in depth. We review the broad spectrum of potential complications as well as their expected time course. These range from the relatively benign to life-threatening and include extracranial herniations, tension pneumocephalus, hygromas, post-traumatic hydrocephalus, infection, new or expanded intraparencyhmal contusions/hemorrhage, extra-axial hemorrhages, and syndrome of the trephined. We discuss the controversies surrounding decompressive craniectomies as well as the pathophyisologic basis of unfavorable outcomes.
Summary/Conclusion
Timely recognition of complications following neurosurgical intervention on the cranial vault via craniotomy, craniectomy, and cranioplasty, is crucial to allow early intervention and prevent additional injury. The astute radiologist, equipped with a knowledge of anatomy and familiar with the expected postsurgical changes is better able to assist the neurosurgeon in the management of these often critically ill patients.

Dural Venous Sinuses: Review of Normal/Variant Anatomy and Common Pathologic Conditions Resulting in Impaired Cerebral Blood Drainage

Rajsheker, S.·Williamson, K. M.·Bourekas, E. C.·Luttrull, M. D.·Nguyen, X.·Slone, H. W.
The Ohio State University Wexner Medical Center
Columbus, OH.

Purpose
The goal of this exhibit is to review dural venous sinus normal and variant anatomy with subsequent discussion regarding common pathology affecting the sinuses.
Approach/Methods
First the normal anatomy will be reviewed using computed tomography (CT) and magnetic resonance (MR) imaging followed by a review of the common normal variants and pitfalls leading to misdiagnosis of dural venous sinus pathology. Various common pathologic conditions affecting the dural venous sinuses then will be discussed with an emphasis on the importance and utility of thorough evaluation with CT and MR venography.
Findings/Discussion
To understand and recognize abnormal dural venous sinuses and the common pathology affecting them it is essential to first know the normal and variant anatomy of the drainage system of the brain and its typical appearance on both CT and MRI. With this knowledge one can easily see direct signs of dural venus sinus obstruction. In less obvious cases there are many indirect signs, such as diffuse brain edema, decreased ventricular size, and venous infarctions, that we must be familiar with in order to ensure a prompt and proper diagnosis of impaired dural venous sinus blood flow. Occlusion or stenosis, and subsequent symptomatology, of the dural venous sinuses can result from a number of pathologic conditions that result in either internal blockage, external compression, or frank invasion. Examples of such conditions include acute or chronic thrombi from such things as infection or trauma; intracranial, cranial, or extracranial masses; and developmental vascular abnormalities. Findings suggestive of dural venous sinus abnormalities may be visualized on

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

standard noncontrast CT images and standard brain MR sequences though it is often imperative to confirm this suspicion with dedicated CT and MR venography, especially in more subtle cases with a coinciding nonspecific clinical presentation.
Summary/Conclusion
Dural venous sinus pathology is difficult to diagnosis because of its variable and nonspecific presentation. It most frequently manifests itself due to compression, invasion, or occlusion resulting in vague symptomatology from the delay of cerebral blood drainage. Delay in diagnosis may lead to high morbidity and mortality; whereas, prompt diagnosis can lead to proper treatment and significantly improve the patient prognosis. Thus, familiarity with the imaging plays a key role in the delineation of normal anatomy and normal variants and is vital in the diagnosis of dural venous sinus pathology.

KEYWORDS: Dural sinus, Dural sinus thrombosis

"Down and Out": Imaging of Various Etiologies of Third Cranial Nerve Palsy

Jarraya, M.[1]·Hayashi, D.[1]·Drissi, C.[2]·Murata, T.[1]·Guermazi, A.[1]·Sakai, O.[1]·Ben Hammouda, M.[2]·Mian, A.[1]
[1]Boston University, Boston, MA, [2]Institute of Neurology, Tunis, TUNISIA.

Purpose
The diagnosis and management of third cranial nerve (CNIII) palsy vary according to the age of the patient, clinical presentation, and associated symptoms. The purpose of our presentation is to review relevant anatomy of CNIII and to present the radiologic findings of CNIII palsy, using magnetic resonance imaging (MRI) and conventional arteriography. Such knowledge contributes to the appropriate clinical management of CNIII pathology.
Approach/Methods
Retrospective review of imaging examinations (brain MRI and arteriography) of patients presenting with CNIII palsy was performed at two tertiary referral centers. Imaging findings were reviewed and correlated with the neuro-ophthalmologic impairment to determine the site of the lesion along the CNIII pathway. Relevant anatomy is reviewed. Nuclear and fascicular arrangement within the midbrain is explained based on previous reports and experimental findings. Anatomical relationships and radiologic anatomy of the cisternal and cavernous portions also are presented. Subsequently examples of different presentations of CNIII palsy are displayed following a comprehensive classification based on the site of the lesion (central, cisternal, or cavernous).
Findings/Discussion
There are many potential causes for CNIII palsy. Anatomical localization of the abnormality is important and depends on the imaging findings and clinical presentation. Central causes include mesencephalic tuberculoma, cavernoma, tumors, and ischemia. Cisternal etiologies can be posterior communicating artery aneurysm, neuritis, sarcoid, and lymphoma. Cavernous etiologies include nasopharyngeal tumor extending to the cavernous sinus, internal carotid artery aneurysm, cavernous hemangioma of the cavernous sinus, pituitary apoplexy, and cavernous sinus thrombosis.
Summary/Conclusion
Third cranial nerve palsy is a common cause of diplopia, ptosis and mydriasis. MR imaging is typically the primary modality used in determining the site and the nature of the lesion. In some cases, conventional angiography also can be helpful. Knowledge of clinical presentation and imaging findings as well as important anatomical relationships of CNIII along its course is crucial in locating the site of the pathology, identifying the etiology and assisting in timely clinical management.

Deep Brain Stimulation: A Comprehensive Pictorial Review

Bansal, V.·Chokshi, F. H.·Mewes, K.·Gross, R. E.·Riva Posse, P.·Mayberg, H. S.·Hudgins, P. A.
Emory University
Atlanta, GA.

Purpose
Deep brain stimulation (DBS) is used for treatment of medically refractory movement disorders and several neuropsychiatric conditions. Optimal outcomes depend on careful patient selection, accurate electrode targeting, and proper follow up for complications. Based on our institution's experience with DBS, we will provide a review of the principles behind DBS, discuss pre and

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

postoperative magnetic resonance imaging (MRI) protocols, and findings that are important for radiologists to convey in their interpretation.
Approach/Methods
Over a six-year period, 370 patients received DBS at our institution. Representative images demonstrate key basal ganglia landmarks, expected stimulator locations, and although rare, surgical complications. MRI protocols that best show landmarks and limitations to imaging are presented.
Findings/Discussion
Deep brain stimulation is FDA-approved for the treatment of medically refractory essential tremor, Parkinson's disease, and - through a humanitarian device exemption - dystonia and obsessive-compulsive disorder. Additional indications under clinical investigation include epilepsy, treatment-resistant depression, chronic pain, Alzheimer disease and addictions. The procedure consists of implanting an electrode in the brain connected to a pulse generator located in a subcutaneous pocket over the upper chest. Precise localization of the electrode tip at the desired target correlates with successful clinical outcomes. Two methods are used for targeting the electrode tip; the *indirect method* relies on measurements, based on a standard atlas, using a coordinate system derived from the anterior and posterior commissures. Alternatively, to better account for variability in individual anatomy, the *direct method* relies on high resolution volumetric MR brain images to directly visualize the intended targets. Due to difficulty in direct visualization with current technologies, a hybrid indirect/direct system is often used. Final placement is ultimately confirmed via intraoperative activation of the electrode and observation of the intended treatment effect, or by direct imaging visualization with MRI and/or CT. For each clinical indication, there may be one to three possible targets for treatment-efficacy; for example, stimulators for Parkinson disease typically target the subthalamic nucleus (STN) or the globus pallidus pars interna (GPi). Additionally, we are one of a few institutions where DBS is being used for treatment-resistant depression, with 26 patients treated to date. In these patients, the subcallosal cingulate white matter is targeted. At our institution, three distinct MRI protocols have been developed for DBS patients: 1. Screening, 2. Preoperative, 3. Postoperative. Each includes the optimal sequences/planes for targeting specific regions and methods to reduce susceptibility on postoperative images. Perioperative complications of stimulator placement include seizure and intracranial hemorrhage. Delayed complications include lead fracture, migration, and infection. It is important to understand the appearance of the stimulator system as well as the expected tip location for proper identification of these complications.
Summary/Conclusion
Deep brain stimulation for medically refractory movement and neuropsychiatric conditions requires in-depth knowledge of neuroanatomy and careful attention to MR acquisition. As a member of the health care team, the neuroradiologist should understand the rationale for stimulator placement and the expected pre and postoperative imaging appearance for optimal patient outcomes.

KEYWORDS: Deep brain stimulator, Basal ganglia anatomy, complications

eEdE-72

Simulation-Based Training in Neuroradiology

Robertson, H. J. F.[1]·Yang, J.[1]·Wojak, J.[1]·Miranpuri, A.[2]
[1]Louisiana State University Health Sciences Center, New Orleans, LA, [2]Medical University of South Carolina, Charleston, SC.

Purpose
The rapid decrease in recent years of patient referrals for cerebral angiography necessitates alternative educational techniques for resident and fellow training in neuroradiology. Such remedial action is necessary now if angiography knowledge in depth is to remain an inherent part of neuroradiology. Simulation-based training (SBT) can be the effective solution to this dilemma.
Approach/Methods
Many neuroradiology training institutions already have a simulation laboratory, or at least access to a regional laboratory. Commercially available vascular procedural simulation devices of high fidelity have highly developed computer programs which can provide virtual reality angiography training and experience using simulated catheters, wire guides, coils and stents. Silastic arterial models can provide training and experience with actual catheters, wire guides and interventional materials for coiling of aneurysms, stent placement and blood clot extraction. An SBT program for individual or team training is developed around established educational principles. It includes an expert level lecture on the procedure and its risks and possible complications, a pretest of subject knowledge, a series of supervised simulations, a post-test and a proctor-trainee debriefing interview. Repeat SBT sessions at several weeks time intervals provide cumulative training metrics to assess individual knowledge and skills development in invasive procedures without risk of patient injury.
Findings/Discussion
Successful outcomes have been shown for SBT applied to subsequent patient procedures in laproscopic surgery, some aspects of orthopedic surgery, anesthesia, endovascular diagnostic and interventional procedures. Simulation-based training can be applied to all interventional procedures in neuroradiology. It can provide continuous assessment of resident and fellow procedural knowledge and manual skills.
Summary/Conclusion
Simulation-based training is an effective method of basic training in interventional procedures in neuroradiology

without risk of patient injury. Preliminary SBT combined with the subsequent patient procedures is expected to result in improved trainee skills and procedural outcomes with minimal technical errors, reduced procedure time and radiation exposure.

KEYWORDS: Educational, Arteriography, simulation

Do You See What I See? Visual Field Deficits from Lesions along the Visual Pathway

Singh, V.[1]·Reede, D. L.[1]·Smoker, W. R. K.[2]
[1]SUNY Downstate University Hospital of Brooklyn Long Island College Hospital, Brooklyn, NY, [2]University of Iowa Hospital and Clinics, Iowa City, IA.

Purpose
• Review the anatomy of the visual pathway. • Learn the types of visual field defects and the location of lesions that produce them. • Develop an imaging-based approach for the evaluation of patients with visual field deficits.
Approach/Methods
Presented in a quiz format, using illustrations, and corresponding CT and MR images, the anatomy of the visual pathway is reviewed from the anterior chamber to the occipital lobe. A variety of lesions involving portions of the visual pathway (optic nerve, optic tract, optic chiasm, lateral geniculate ganglion), optic radiations (Myer's and Braun's loops) and occipital cortex are present including traumatic, neoplastic and inflammatory pathologies.
Findings/Discussion
Emphasis is placed on understanding the anatomical basis for the corresponding visual field deficits.
Summary/Conclusion
Imaging can be crucial in determining the cause, as well as correlating the location of a lesion along the visual pathway, with the type of visual deficit observed on clinical examination. After viewing this exhibit the viewer will be familiar with the anatomy of the visual pathway, the type of lesions encountered and expected visual field deficit based on a lesion's location.

KEYWORDS: Visual pathways, Visual loss, visual system

eEdE-74

In Limbo: A Review of the Limbic System Imaging Anatomy

Garcia, L. E.·Jay, A.
Georgetown University Hospital
Washington, DC.

Purpose
The limbic system is composed of a complex network of cortical and subcortical structures involved in many aspects of brain function, including learning, memory, and emotional behavior. It also is involved in many neuropathologic conditions, both isolated or as part of more diffuse processes due to its robust connections with the rest of the brain. Even though it plays an important role in both the structural composition and pathology affecting the brain, not many radiologists feel comfortable evaluating it. We aim to familiarize the participants of this educational exhibit with the normal imaging anatomy of the limbic system and review some common pathology affecting this region.
Approach/Methods
We begin by giving a brief overview of the limbic system embryology. We then proceed to show imaging anatomy of the limbic system divided into cortical and subcortical regions. Examples of pathology involving the limbic system in different disease categories will be shown.
Findings/Discussion
The limbic system's relation to memory and emotional aspects of brain function stems from its embryologic relation to primitive regions of the brain containing a trilaminar cortex architecture, and its communication with more modern regions containing a six-layer cortex. The limbic system's intricate and complex anatomy is best evaluated by magnetic resonance multiplanar imaging. The system is better understood when divided into cortical and subcortical structures. The cortical structures include the parahippocampal and cingulate gyri, hippocampus, and fornices. The subcortical structures include the amygdala, septal area, thalamus, hypothalamus, and mamillary body. The limbic system is involved by many disease categories, including congenital, malignant, infectious, neurodegenerative, ischemic, traumatic, and epileptogenic disorders. Involvement may be isolated to this region or may be secondarily involved by a more diffuse process originating in another region of the brain.
Summary/Conclusion
The limbic system is an important component of the brain and is involved in many disease processes. Therefore, familiarity with normal imaging anatomy of this region provides radiologists with an important tool in making diagnostic decisions and avoid remaining in limbo when it comes to helping both patients and referring physicians.

KEYWORDS: Anatomy, Limbic system

eEdE-75

Functional Anatomy and Pathology of the Corpus Callosum: Correlation with Diffusion Tensor Imaging

Lee-Felker, S.·Felker, E.·Salamon, N.
University of California Los Angeles
Los Angeles, CA.

Purpose
To highlight the use of diffusion tensor imaging (DTI) in understanding the functional organization of the corpus callosum, with anatomical-clinical correlation of corpus callosum pathology.
Approach/Methods

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

First we will review the anatomy and functional topography of the corpus callosum on DTI. Then we will illustrate a variety of pathologic conditions affecting the corpus callosum, including congenital anomalies, demyelinating diseases, infarctions, neoplasms, and neurocognitive disorders.
Findings/DIscussion
The corpus callosum is the main white matter fiber bundle connecting the two brain hemispheres. Despite advances in modern neuroimaging techniques, we have yet to fully understand the functional organization of the corpus callosum and how it is altered in a variety of pathologic conditions. Diffusion tensor imaging is widely available with the ability to obtain both morphologic and quantitative values of structures such as the corpus callosum for assessing functional aspects of disease.
Summary/Conclusion
This exhibit demonstrates the functional topography of the corpus callosum with various pathologic conditions. Diffusion tensor imaging is helpful as an additional, practical imaging tool to illustrate functional mapping for correlation with clinical assessment and treatment planning.

KEYWORDS: Diffusion tensor image, Corpus callosum

eEdE-76

Optic Pathways from Anatomy to Pathology: A Pictorial Essay and Review

Aragao, M. F. V.[1]·Pereira, B. P. G.[1,2]·Lima, L. T. B.[1,2]·Morais, T. P.[1,2]·Araújo, A. C. C.[3]·Filho, E. A.[1,2]
[1]Multimagem, Recife, BRAZIL, [2]Hospital das Clinicas - UFPE, Recife, BRAZIL, [3]Hospital Esperanca, Recife, BRAZIL.

Purpose
Since the early stages of development of radiology, imaging of the visual pathways has been a challenge, and usually involved the use of plain radiographs, complex motion tomography, or invasive techniques such as orbital venography and pneumoencephalography. Nowadays, sectional imaging techniques have prevailed as the preferred examination. In this pictorial essay we intend to provide a practical and objective approach regarding the multiple pathologic conditions that affect the visual pathways, with special interest in the correlation between their CT, MR and advanced MR imaging findings, anatomical localization and clinical symptomatology.
Approach/Methods
The CT, MR and advanced MR images of congenital, tumoral, infectious, inflammatory, demyelinating and vascular conditions affecting the optic nerve, optic chiasm, optic tracts, optic radiations and visual cortex of multiple patients were obtained in our institution. All the cases were reviewed posteriorly and confirmed through histopathologic examination whenever feasible. The main patient characteristics (gender, age, familiar and pathologic history) and the main lesion characteristics (location, morphology, density, signal intensity and contrast enhancement) were described and extensively discussed.
Findings/Discussion
Usual indications for imaging of the visual pathways generally involve variable degrees of visual loss. Rapidity of onset of the symptoms alongside correct evaluation of specific visual field deficits and patient's epidemiologic characteristics usually allow a high degree of clinical suspicion regarding the wide array of possible underlying conditions. Sectional imaging techniques commonly are tailored to display the expected condition optimally. Anatomical location and lesion morphologic characteristics are essential information for the development of an accurate diagnosis.
Summary/Conclusion
In this electronic education exhibit we provide a concise yet complete description of the key imaging findings observed in the most common visual pathways pathologic processes. MR imaging has a major role in visual pathways imaging and as such is discussed more extensively.

KEYWORDS: Optic nerve, Orbits, optic chiasm

eEdE-77

Vascular Anatomy of the Deep Gray Matter: A Review of Normal Arterial and Venous Circulation, Anatomical Variants, and Associated Pathology of the Basal Ganglia and Thalami

Yam, B. L.·Maralani, P. J.·Mohan, S.
Hospital of the University of Pennsylvania
Philadelphia, PA.

Purpose
The deep gray matter arterial supply and venous drainage is complex with extensive variations. Thorough knowledge of this vascular anatomy is essential for localization of vascular pathology. The purpose of this exhibit is to review the arterial and venous circulation of the deep gray matter, correlate with cross-sectional and angiographic imaging techniques, demonstrate associated pathologic processes using a multimodality approach, and review the relevant imaging and anatomy literature.
Approach/Methods
We will discuss the relevant embryology and normal and variant vascular supply of the caudate, putamen, globus pallidus and thalamus through illustrations and correlative cross-sectional and angiographic techniques. The vascular supply of the internal and external capsules also will be addressed due to their proximity and clinical significance. We then will demonstrate arterial and venous pathology involving the deep gray matter nuclei using correlative multimodality imaging.
Findings/Discussion
The basal ganglia and thalami are clusters of paired deep gray matter structures that have an intricate vascular supply. Knowledge of the normal and variant vascular

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

anatomy of these structures is important to help determine the etiology of associated vascular pathology, as well as to localize the involved vessels. Diseases of various intracranial arterial and venous branches cause distinctive patterns of ischemia or infarction of the basal ganglia and thalami. Following initial characterization by cross-sectional imaging, digital subtraction angiography may help improve characterization of vascular abnormalities of the deep gray matter and help narrow the differential diagnosis.
Summary/Conclusion
This review outlines the embryology, vascular anatomy and associated pathology of the basal ganglia and thalami. Imaging characteristics and patterns of vascular pathology affecting the deep gray structures are highlighted to demonstrate the anatomical basis of pathology.

KEYWORDS: Basal ganglia anatomy, Basal ganglia disease, vascular anatomy of the deep gray matter

Basal Cisterns Revisited

Ratcliffe, M. R.·McCreary, R.·Siripurapu, R.·Herwadkar, A.
Salford Royal Hospital
Salford, UNITED KINGDOM.

Purpose
To demonstrate the anatomy of the basal cisterns, their contents and arachnoid membranes using modern high resolution imaging techniques with particular focus on correlating with pathologic processes affecting the vessels and nerves.
Approach/Methods
We present an electronic educational exhibit highlighting the basal cistern anatomy. We then will review pathologies that may be encountered in the basal cisterns as they affect various nerves and vessels as well as there relation to the adjacent arachnoid membrane. Tumor spread, patterns of SAH and surgical approaches will be discussed.
Findings/Discussion
The basal cisterns are a complex network of subarachnoid spaces separated from each other by a trabeculated porous wall with various sized openings. It is of clinical significance that cerebral arteries, veins and cranial nerves pass through these subarachnoid spaces. The anatomy is essential to understand the different direction of aneurysm growths and pattern of blood spread in patients with subarachnoid hemorrhage. The anatomy of various cranial nerves in the cisternal portion and their relation to the adjacent vessels is important when determining neurovascular conflicts. Tumor locations and extensions especially in the posterior fossa is predicted by the anatomy of the cisterns and the arachnoid.
Summary/Conclusion
This educational exhibit highlights the importance of understanding the normal basal cistern anatomy with particular focus on vascular and cranial nerve pathologies.

KEYWORDS: Anatomy, basal cisterns

eEdE-79

MR Angiography Evaluation of Anatomical Variants and Anomalies Affecting Circle of Willis

Baxi, A.·Jay, A.·Lee, C.·Berkowitz, F.
MedStar Georgetown University Hospital
Washington, DC, DC.

Purpose
1. To describe normal imaging appearance of circle of Willis on magnetic resonance (MR) angiography. 2. To describe potential collateral pathway and anastomosis between internal carotid (anterior) and vertebral arteries (posterior circulation). 3. To study normal variants and anomalies in circle of Willis and review their radiologic and clinical significance.
Approach/Methods
The circle of Willis is a major source of blood supply to the brain. A complete circle of Willis is seen only in 50% of cases. It is formed by anastomosis and collaterization between internal carotid (anterior) and vertebral arteries (posterior circulation).This communicating pathway allows adequate distribution of cerebral blood flow and perfusion not only between right and left side but also between anterior and posterior parts of the brain in the event of intra and extracranial carotid and vertebral artery occlusive disease. It is thus very important to know the embryonic development, prevalence and clinical relevance of various anatomical variants and anomalies of circle of Willis with respect to the pathology with which they are associated. An attempt is made in this educational exhibit to describe normal imaging appearance, anatomical variants and anomalies of circle of Willis on MR angiography. Magnetic resonance angiography of brain performed in patients for various clinical indications was reviewed and studied for normal circle of Willis, its anatomical variants and anomalies.
Findings/Discussion
The circle of Willis is formed when the internal carotid artery on each side divides into the anterior and middle cerebral arteries. The anterior cerebral arteries then are united by an anterior communicating artery. Posteriorly, the basilar artery which is formed by union of left and right vertebral arteries branches into right and left posterior cerebral arteries which communicates with the internal carotid system anteriorly via the right and left posterior communicating arteries respectively. Common anatomical variants and anomalies we encountered were: 1. Hypoplasia or absent arteries, 2. Fetal origins of PCA, 3. Infundibular dilatations, 4. Persistent carotid-basilar artery anastomoses such as primitive trigeminal, hypoglossal and otic arteries, 5. Fenestrations, duplications, accessory and early bifurcations of cerebral arteries, 6. Azygous and

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

hemispheric ACA, median artery of corpus callosum, and 7. Aberrant and proatlantal anomalies of ICA.
Summary/Conclusion
The circle of Willis is an anastomotic system of arteries that sits at the base of the brain. It is very important for a radiologist to know normal anatomy, anatomical variants and anomalies of circle of Willis to understand physiology of blood redistribution and their significance in pathologies affecting brain. The major teaching points of this educational exhibit are: 1. Imaging appearance of normal circle of Willis, anatomical variants and anomalies on magnetic resonance angiography. 2. Identification of potential anastomotic collaterals between anterior and posterior circulation. 3. Clinical importance of normal variants and anomalies with respect to patient management.

KEYWORDS: MR angiography, Normal variant, circle of Willis

eEdE-80

The Veins of the Posterior Cranial Fossa in Health and Disease

McCreary, R.·Ratcliffe, M. R.·Siripurapu, R.·Herwadkar, A.
Salford Royal Hospital
Salford, UNITED KINGDOM.

Purpose
To review the posterior fossa venous anatomy in health and disease using contemporary cross-sectional and DSA techniques.
Approach/Methods
We present an electronic exhibit highlighting the posterior fossa venous anatomy and its relevance during neurovascular and open surgical procedures using cross-sectional imaging and catheter angiography. CT venography, MR venography and intra-arterial DSA studies are included in the discussion.
Findings/Discussion
The venous drainage of the posterior fossa is comprehensively discussed. We demonstrate the utility of understanding the venous drainage of the brainstem and cerebellum in evaluating various vascular and nonvascular pathologies affecting the posterior fossa. Various intracranial and skull base surgical cases are illustrated to highlight the relevance of understanding the venous anatomy and variations for surgical planning and understanding postoperative complications.
Summary/Conclusion
This educational exhibit highlights the importance of understanding the venous drainage of the posterior fossa in evaluating various vascular and nonvascular conditions.

KEYWORDS: Venous anatomy, Posterior fossa

eEdE-81

Test Your Knowledge: Anatomical Variations of the Cerebral Arterial Circulation - A Case-Based Review

Felker, E. R.·Lee-Felker, S. A.·Salamon, G. G.·Salamon, N.
David Geffen School of Medicine
Los Angeles, CA.

Purpose
Variations in the cerebral arterial circulation are common; with improvements in image quality and easy access to MR angiography (MRA) and CT angiography (CTA), they are being recognized more frequently. Knowledge of these variants is important for accurate interpretation, as some variants can influence surgical and interventional procedures. The purpose of this exhibit is to provide an interactive review of common cerebral arterial variants whereby viewers can test their knowledge in a quiz-based format.
Approach/Methods
We will briefly review the normal anatomy and embryology of the cerebral arterial circulation. Then we will provide examples of the most common and clinically relevant anatomical variants, highlighting the appearance, prevalence, and associations of each. Cases will be illustrated with MRA, CTA, and conventional catheter angiography. Each case will be followed by multiple-choice questions that highlight important aspects.
Findings/Discussion
Fenestrations, persistent carotid-vertebrobasilar anastomoses and aberrant arteries in the skull base comprise the majority of clinically important anatomical variants. They may be associated with other intracranial vascular abnormalities, most commonly aneurysms and cranial nerve symptoms. Embryologic remnant networks can be used as collaterals. Knowledge of anatomical variants, common anastomoses and potential vascular networks is important for radiologists to better understand pathophysiology and treatment planning.
Summary/Conclusion
Cerebral artery variants often are identified in daily vascular imaging. Precise knowledge of these anatomical variants not only can aid in the detection of other associated intracranial vascular abnormalities but also can lead to better understanding of collateral networks and suggest treatment planning for interventional and neurosurgical procedures.

KEYWORDS: Anatomical variation, circle of Willis

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eEdE-82

The Absent Carotid Artery: Congenital or Acquired?

Jung, M. W.·Griffith, B.·Kelly, M.·Shahin, G.·Sanders, W.·Kole, M.·Marin, H.
Henry Ford Hospital
Detroit, MI.

Purpose
The goal of this educational exhibit is to illustrate the fundamentals of internal carotid artery anatomy from an embryologic perspective, create a systematic approach for assessment of congenital internal carotid artery anomalies and demonstrate its relevance in the endovascular treatment of acquired arterial disease. Medical illustrations and selected angiography cases from our institution will be provided.
Approach/Methods
Various cases of congenital ICA anomalies from a segmental embryologic perspective will be shown using multimodal imaging and angiographic correlation. Patterns of collateral flow pathways will be discussed with regard to endovascular treatment. Cases of acquired internal carotid occlusions will be shown with regard to different pathways of collateral flow.
Findings/Discussion
Patterns of collateral flow from internal carotid artery occlusion/dysgenesis can be divided into three pathways: 1) circle of Willis anastomoses, 2) Persistent embryologic arteries and 3) External to internal carotid artery anastomoses. Persistent embryologic arteries include the trigeminal, hypoglossal and proatlantal intersegmental arteries, for which examples are provided. Understanding the embryologic origin of the internal carotid artery and potential collateral flow is important for differentiating congenital from acquired disease and for avoiding complications during endovascular procedures.
Summary/Conclusion
At the completion of this educational exhibit, the individual should be able to understand internal carotid anatomy from an embryologic perspective, congenital internal carotid artery anomalies, and differentiate acquired internal carotid artery occlusion from congenital anatomical variants.

KEYWORDS: Carotid artery, Congenital anomalies

eEdE-83

The Floor of the Third Ventricle: Anatomical, Physiologic, Pathologic and Surgical Review

Burgin, K.·Kumar, M.·Ramakrishnaiah, R.·Samant, R.·Fitzgerald, R.·Van Hemert, R.·Angtuaco, E.
University of Arkansas for Medical Sciences
Little Rock, AR.

Purpose
Hypothalamic dysfunction results in systemic symptoms that may have little to no neurologic deficits. Emotional disturbance, growth difficulties, water imbalance, sleeplessness and weight problems are oftentimes the primary clinical presentation. Our exhibit seeks to highlight the anatomy and physiology associated with this area and we will present pathologic entities associated with the hypothalamus in its primary location along the floor of the third ventricle. The surgical approach for abnormalities also will be reviewed.
Approach/Methods
A retrospective review for hypothalamic abnormalities was conducted using an extensive database search for the last ten years at tertiary adult and pediatric hospitals which were studied by both CT and MRI. Surgical correlative data with pathology were available in most of the cases. These pathologic entities are discussed with a review of the normal representative anatomy of the floor of the third ventricle. Each pathologic entity was reviewed with its effect on the normal anatomy of the third ventricle.
Findings/Discussion
A pictorial review of the normal anatomy and various pathologic entities affecting the floor of the third ventricle will be shown. Relevant imaging findings will be presented. Primary lesions of the floor of the third ventricle starting from the optic chiasm, pituitary infundibulum, tuber cinereum and mamillary bodies will be discussed. Pathologic entities to be shown are congenital, developmental, inflammatory, tumoral and vascular processes that primarily affect this area as well as adjacent lesions that secondarily distort the floor of the third ventricle. Discussion of the effect on the hormonal physiology important in this area will be discussed. Surgical approach to masses in this area also will be shown.

Summary/Conclusion
This review will highlight the important anatomy and specific pathology related to the third ventricle floor using

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

modern neuroimaging studies to highlight their importance in defining the systemic symptoms that are associated with abnormalities in this critical part of the brain.

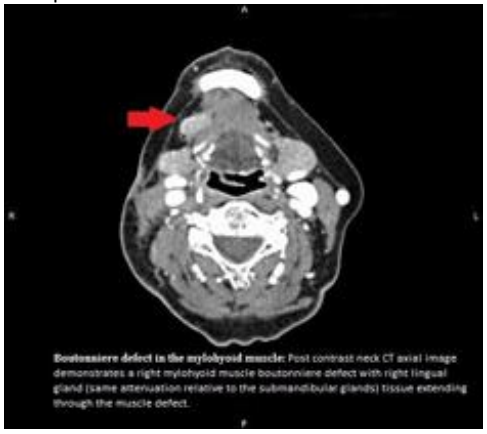
KEYWORDS: Third ventricle, Hypothalamus

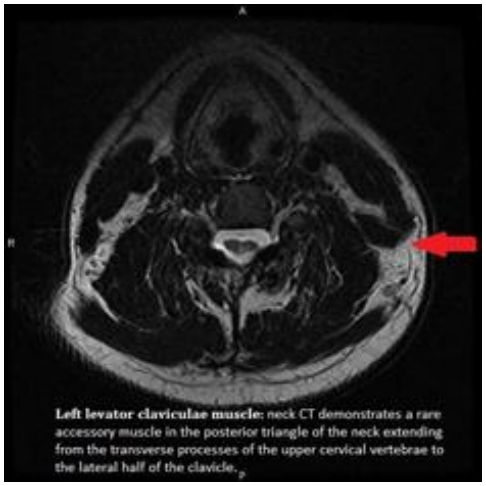
eEdE-84

Anatomy of Neck Muscle Variations

Rubinstein, D.·Valladares Otero, A.
University of Colorado
Aurora, CO.

Purpose
The purpose is to describe the anatomy of neck muscle variations. Most neck muscle variations are asymptomatic, however it is important to be able to differentiate them from pathology such as lymphadenopathy or soft tissue metastasis. It also is important to identify them as a cause of palpable abnormality that a patient or a physician may encounter.
Approach/Methods
Retrospective evaluation of neck CT and MR scans performed for a broad variety of indications, excluding patients with neck surgery or neoplasm which could confound identification of neck muscles. We looked for supernumerary, anomalous and absent muscles, muscle defects and alternate origin/insertion of neck muscles.
Findings/Discussion
Multiple neck muscle variations and anomalous muscles were demonstrated, including but not limited to boutonniere defect in the mylohyoid muscle, anomalous muscles such as the cleidooccipital muscle and levator claviculae, accessory muscles such as anterior digastric muscle bundles, variations in muscle insertions such as a clavicular origin of the omohyoid inferior belly, absent muscle bellies such as an absent anterior digastric and absent inferior omohyoid inferior belly. These are some examples of the muscle variations we have encountered.





Summary/Conclusion
Numerous muscle variations have been described by anatomists, most tend to be asymptomatic; however, some may result in palpable abnormalities or potentially can be confused with pathology. The diagnosis of an anomalous muscle or neck muscle variation should be borne in mind when evaluating neck imaging.

KEYWORDS: Anatomical variation

eEdE-85

When Your Eye Goes in and the Sixth Nerve Goes Out: A Review of Sixth Cranial Nerve Anatomy and Pathology

Smittkamp, C.[1]·Smoker, W.[1]·Reede, D.[2]·Gentry, L.[3]
[1]University of Iowa, Iowa City, IA, [2]East Manhattan Diagnostic Imaging, New York, NY, [3]University of Wisconsin, Madison, WI.

Purpose
• Review the anatomical course of the sixth cranial nerve. • Be able to identify important anatomical landmarks on imaging studies. • Review various pathologies relevant to particular segments of the sixth cranial nerve.
Approach/Methods
This viewer-interactive, electronic exhibit breaks down the course of the sixth cranial nerve (abducens) from its nucleus to the lateral rectus muscle into six manageable anatomical segments: nuclear, cisternal, skull base, cavernous sinus, orbit, lateral rectus muscle. Each segment is assessed in the same three ways. First, a custom illustration highlighting important adjacent structures and anatomical landmarks is presented. This will help the reader develop a conceptual view of the region. Second, a set of corresponding MR and/or CT images illustrates the same anatomical region. This will help translate the conceptual view of the anatomy into the ability to identify key anatomical landmarks on cross-sectional imaging studies. Knowledge of adjacent structures is important in the ability to clinically localize pathology and, thereby, direct imaging to the appropriate location. Finally, multiple cases are presented that demonstrate the various

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

pathologies that may occur in each of the anatomical segments.
Findings/Discussion
Pathologies exemplified include demyelination, tumor, inflammation, infection, trauma, vascular compression, and idiopathic causes.
Summary/Conclusion
Double vision secondary to sixth cranial nerve palsy is the most common isolated cranial nerve palsy, yet rarely addressed. It often is accompanied by other clinical findings, unique combinations of which may help localize lesions to the appropriate segment. Imaging assessment can best be achieved by a thorough understanding of the nerve's anatomical course and nearby structures. We aim to solidify this knowledge by providing a review of sixth cranial nerve anatomy through illustrations and cross-sectional imaging followed by viewer-interactive examples of various pathologies that affect the six segments of the sixth cranial nerve.

Behind the Name: Eponyms of Neuroradiology

Chow, D. S.·Miloushev, V.·Garger, A. A. V.·Dipoce, J.·Utukuri, P.·Filippi, C. G.·Lignelli, A.
Columbia University
New York, NY.

Purpose
There are numerous eponyms encountered within neuroradiology given its rich history. Eponyms are pervasive throughout medicine and are used to communicate complex pathologies while honoring an individual in a given field. The purpose of this exhibit is to review and define commonly used eponyms in neuroradiology.
Approach/Methods
This exhibit will categorize various eponyms encountered in neuroanatomy, neuropathology, and diagnostic techniques. Eponyms will be grouped anatomically: (1) cerebral hemispheres, (2) posterior fossa, (3) sella and pituitary, (4) vascular structures, and (5) spine. A pre and postinteractive quiz module will be provided for users to assess their knowledge.
Findings/Discussion
An organized and illustrative spectrum of eponyms relevant to neuroradiology is provided. A biographical sketch, representative imaging, and radiologic teaching points will accompany each described eponym. Familiarity with eponyms is important for understanding complicated disease processes and for accurate communication with other physicians.
Summary/Conclusion
There are numerous eponyms encountered in neuroradiology. Knowledge of these eponyms is important for minimizing confusion with colleagues and referring physicians. Additionally, it allows for an opportunity to remember individuals who have contributed to our field.

"Am I Getting on Your Nerves?": Anatomy and Pathology of Nerves in the Infrahyoid Neck

Font, S.[1]·Reede, D.[1]·Smoker, W. R. K.[2]·Gentry, L.[3]·Holliday, R.[4]
[1]SUNY Downstate at Long Island College Hospital, Brooklyn, NY, [2]University of Iowa Hospitals and Clinics, Iowa City, IA, [3]University of Wisconsin Hospital and Clinics, Madison, WI, [4]The New York Eye and Ear Infirmary, New York, NY.

Purpose
1. Learn the location of major nerves in the infrahyoid neck. 2. Demonstrate the imaging findings of common lesions affecting the nerves. 3. Review clinical findings associated with nerve involvement.
Approach/Methods
Information is presented in a quiz format using illustrations and corresponding cross-sectional images to provide a comprehensive review of infrahyoid neck nerve anatomy. This is followed by case presentations with emphasis on the location of pathology with reference to nerves, imaging findings and clinical symptoms. Lesions discussed include: • Vagus nerve X-(Nerve sheath tumors, extrinsic compression of the recurrent laryngeal nerve-above and below the thoracic inlet). • Spinal Accessory nerve XI-(Nerve sheath tumors and secondary involvement by adjacent tumor). • Phrenic nerve-(Secondary involvement by tumor). • Brachial plexus-(Pancoast tumor, nerve sheath tumor, nerve root avulsion). • Sympathetic plexus-(Nerve sheath tumor, extrinsic compression).

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Findings/Discussion
A wide variety of pathology occurs in the infrahyoid neck where the anatomy is complex. A number of nerves from different origins (cranial, cervical, sympathetic and brachial plexuses) traverse this region. An understanding of the nerve anatomy enables one to identify primary and potential extrinsic nerve involvement based on lesion location and/or clinical symptoms. This information may have significant impact on treatment planning.
Summary/Conclusion
Nerve involvement may be due to intrinsic or extrinsic pathology. Knowledge of the location of the nerves in the infrahyoid neck and common pathologies encountered in this region will increase the accuracy of imaging interpretation. Upon completion of this module, the user will have improve his/her ability to interpret cross-sectional images of the infrahyoid neck including identifying lesions originating in or potentially involving, major nerves. This information is important for surgical planning and may improve patient outcomes.

KEYWORDS: Anatomy, Nerve imaging

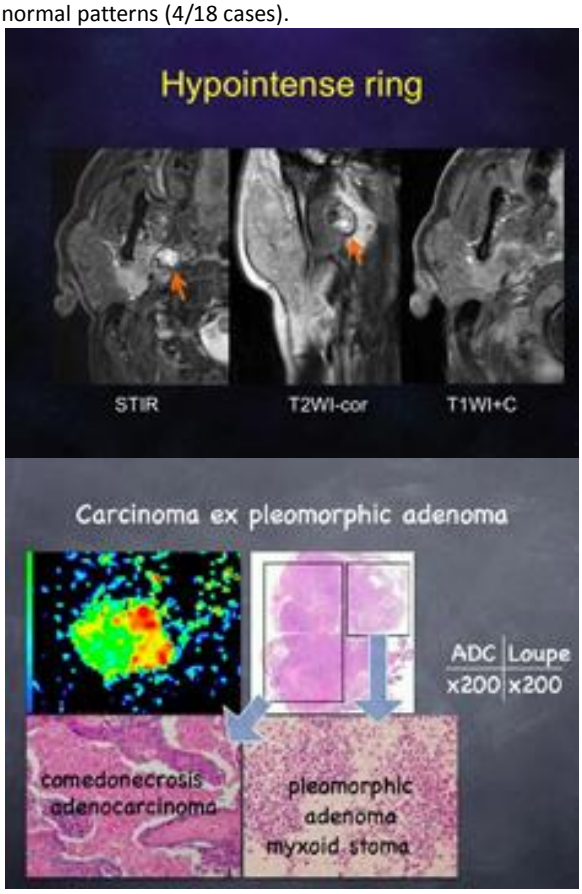
The Diagnostic Features on MR Imaging of Carcinoma ex Pleomorphic Adenoma

Yokota, H.･Motoori, K.･Horikoshi, T.･Mukai, H.･Inoue, K.･Higashide, T.･Okamoto, Y.･Uno, T.
Chiba University Hospital
Chiba, JAPAN.

Purpose
Pleomorphic adenoma is the most common benign neoplasm of salivary gland origin. The incidence of malignant transformation is about 10% in those present for more than 15 years. Observation is a selection on elderly patients. Carcinoma ex pleomorphic adenoma (CXPA) must be diagnosed before this selection. The usefulness of fine-needle aspiration cytology in salivary tumors continues to be a controversial subject. Radiologists should recognize that MR imaging also is useful for estimating the pathology of CXPA and demonstrating their morphology and extent.
Approach/Methods
Eighteen cases of CXPA (14 parotid gland, 2 submandibular gland, 2 minor salivary gland) were identified from our imaging database. Key imaging characteristics with histopathologic images of these cases are presented.
Findings/Discussion
Key sequences are T2-weighted image, dynamic study and diffusion-weighted image. The cases with ring-shaped hypointense nodule in the tumors on T2-weighted image are classified as invasive type of CXPA (9/18 cases). This ring nodule represented a capsule of pleomorphic adenoma. The cases without ring nodule are classified as noninvasive type. In half of these cases, malignant components can be detected in the tumors (5/18 cases).
Peak time and wash out ratio on time intensity curve of dynamic study are effective for differentiating salivary tumors. Low value of apparent diffusion coefficient (ADC) often presents malignant tumor. Combination of these techniques produces more accurate diagnosis of malignant salivary gland tumors. The residual half cases present normal patterns (4/18 cases).



Summary/Conclusion
Carcinoma ex pleomorphic adenoma presents different patterns depending on invasion from capsule. The ring nodule in the tumor is a characteristic sign of invasive type of CXPA. Combination of dynamic study and ADC measurement is essential for diagnosing noninvasive type of CXPA.

KEYWORDS: Salivary gland, Carcinoma

eEdE-88

Old is Gold: Role of Conventional Sialography in Modern Radiology - With Emphasis on Sjögren Syndrome and Sialoendoscopy

Chaudhry, U. S.·Maley, J. E.·Policeni, B.·Schularick, N.·Hoffman, H. T.
University of Iowa, Hospitals and Clinics
Iowa City, IA.

Purpose
A large segment of the population suffers from salivary gland disease, constituted by a wide array of pathology. One common cause is Sjögren syndrome, an autoimmune disorders affecting 0.5 to 3 million people in the U.S. alone. Conventional sialography was a standard diagnostic modality for such diseases, but preference shifted to noninvasive techniques such as MRI and CT sialography. With the advent of sialoendoscopy and related techniques, conventional sialography has seen a resurgence. Additionally, (our experience suggests) conventional sialography in diseases such as Sjögren syndrome may have competitive diagnostic accuracy as compared to new modalities. It therefore is more important than ever to have a good understanding of the procedure, findings, advantages and limitations of conventional sialography.
Approach/Methods
We performed a retrospective review at University of Iowa of a total of 103 sialograms performed at our tertiary care center from 2008 to 2012. We highlight several interesting cases, with a literature review of key pathologies evaluated through sialography.
Findings/Discussion
Conventional sialography was first established in 1904 by Carpy, and has not seen much of an evolution as far the technique of the study is concerned. Briefly, the study involves dilation of the ductal orifice, followed by insertion of a specialized catheter and injection of contrast. An advantage of this modality over MR sialography is that it gives better spatial resolution of the gland. Also dilatation of the ductal orifice helps determine the need for a papillotomy and also establishes the presence or absence of stenosis at the orifice. This is something that is particularly useful in preoperative planning. In our exhibit we present a brief summary of major salivary gland anatomy and basic technique in conventional sialography. Some normal examples are used for this illustration. Contrast agents and standardizing suggestions then are discussed. After which conditions such as Sjögren's, sialoliths and sialosis are reviewed with examples of cases. Special emphasis is given to Sjögren syndrome and the grading used in sialography.
Summary/Conclusion
Conventional sialography offers a unique insight in salivary gland pathology with advantages lacking in other available imaging modalities. With otolaryngologists utilizing and relying on this age-tested technique, it is more imperative than ever that neuroradiologists have a firm grasp of this modality.

KEYWORDS: Salivary gland, Sjögren's syndrome, sialography

eEdE-89

Imaging and Management of Maxillofacial Trauma: What the Surgeon Needs to Know

Khorrami-Arani, N.[1]·Liang, T.[2]·Nicolaou, S.[1]
[1]Vancouver General Hospital, Vancouver, BC, CANADA,
[2]University of British Columbia, Vancouver, BC, CANADA.

Purpose
Maxillofacial (MF) trauma presents with a unique spectrum of injuries and characteristic image findings. Imaging plays a critical role in identifying these injuries and influencing their management. Emerging technologies and techniques also have made imaging faster, more accurate, and safer by reducing radiation dose exposure. The purpose of this exhibit is to review the anatomy and mechanism of spectrum of the injuries, the various imaging modalities available and characteristic imaging findings. A management algorithm for evaluation of MF trauma from the maxillofacial surgeons perspective will be described.
Approach/Methods
A retrospective review of MF trauma cases at our institution will be conducted for imaging examples to demonstrate the spectrum of these injuries.
Findings/Discussion
This educational exhibit will review the epidemiology, anatomy, mechanism of injury, and parameters for clinical assessment of MF trauma. Imaging modalities for MF trauma including radiographs, MDCT, MRI will be reviewed, with the emphasis on MDCT with volume rendering as the imaging exam of choice. The spectrum of injuries including nasal, frontal sinus, orbital, zygoma, maxillary and mandibular fractures and globe injuries will be discussed. Additionally, the characteristic findings, imaging examples of MF trauma on MDCT, and their clinical significance will be demonstrated. Imaging mimics and diagnostic pitfalls will be discussed and imaging examples will be demonstrated to help readers avoid these diagnostic errors. A discussion of the usefulness and limitations of MDCT in the setting of determining management and surgical exploration for these injuries will be employed. Finally, an imaging and management algorithm for MF trauma from the surgeons perspective will be proposed and reviewed.
Summary/Conclusion
Maxillofacial trauma presents with a unique spectrum of injuries and characteristic imaging findings which have been reviewed in this exhibit. The utility of MDCT with volume rendering for imaging of MF trauma in both diagnosis and determination of a surgical versus conservative management have been demonstrated in this

exhibit. A useful algorithm for imaging and management of MF trauma has been proposed and can be adapted easily to radiologists' and trauma surgeon's practices.

KEYWORDS: Facial fractures, maxillofacial trauma

eEdE-90

Perineural Spread in the Head and Neck: Now You See It, Now You Don't!

Khledi, R. A.·Sheitt, H.·Gommsani, R. E.·Adas, R. A.
King Abdulaziz Medical City
Jeddah, SAUDI ARABIA.

Purpose
To review the clinical and radiologic features of perineural spread of disease in cross-sectional imaging and briefly discuss the common pathologies and sites.
Approach/Methods
We retrospectively reviewed the neck and skull base studies of adult patients with perineural spread of diseases in our institution from January 2012 to present. We also reexamined the different pathologies and most common sites of involvement in these patients.
Findings/Discussion
Our understanding of perineural spread of disease has evolved over the last century. Although it is seen more commonly in malignant rather than benign lesions, they can occur in a wide variety of pathologies. They may be radiographically evident before the onset of clinical silence. It is important to distinguish between perineural invasion and spread. Invasion occurs when microscopic cells are seen surrounding small nerve branches. As such it cannot be seen on imaging and it is an ominous prognostic sign associated with an increased local recurrence rate and decreased survival. The exact mechanism of perineural spread is still poorly understood. The most accepted current theory is that nerves provide a pathway of least resistance for lesion growth. The diagnosis of perineural spread is clinical. Imaging often is used to confirm the clinical suspicion. Computed tomography and MRI play a very important role in the evaluation of perineural spread, but MRI has become the modality of choice. MR imaging is superior to CT in providing more accurate assessment of intracranial spread to the Meckel's cave, the cavernous sinus, the internal auditory canal or cerebellopontine angle while CT scans are superior to MRI for evaluating bony changes, which are important because a substantial portion of the cranial nerves are contained within bony structures. Areas to look for bony changes include: the supraorbital foramen, pterygopalatine fossa, foramen rotundum, vidian canal, palatine foramen, foramen ovale, mandibular foramen, and stylomastoid foramen. Among the radiologic findings to look for are neural thickening and enhancement which may lead to foraminal enlargement and destruction, obliteration of the fat planes at foraminal openings, neuropathic atrophy, and convexity of the lateral cavernous sinus wall. Preoperative diagnosis of perineural spread/invasion is an important factor in guiding both surgical and radiation treatment planning. It also has serious staging and prognostic implications. Treatment guidelines differ according to the primary pathology and the sites involved, but radiation therapy is the main line of treatment following surgery.
Summary/Conclusion
Perineural spread/invasion in the head and neck is a serious entity that has important implications on prognosis and treatment of different diseases. Imaging plays an essential role in determining the site and extent of the disease, sometimes even before the onset of clinical symptoms.

KEYWORDS: Perineural, Cranial nerve pathology

Spectrum of Temporomandibular Joint Pathology: A Pictorial Review

Nundkumar, A.·Shen, P.·Lee, P.
University of California Davis
Sacramento, CA.

Purpose
This is a pictorial review characterizing the wide range of pathology of the temporomandibular joint (TMJ) rarely encountered in practice. Our review includes, primary tumor, infection, and arthritides.
Approach/Methods
Retrospective multicenter analysis of cases with primary or secondary pathology involving the TMJ joint was performed. Specific educational cases with representative images were selected.
Findings/Discussion
In our experience, pathology of temporomandibular joint beyond trauma and osteoarthritis is infrequently encountered. However to add some clarity to the wide spectrum of TMJ disorders, the various TMJ entities were organized into categories of: trauma, infectious, arthropathies, vascular, benign and malignant masses. Arthropathies of the TMJ include rheumatoid arthritis, osteoarthritis and calcium pyrophosphate dehydrate arthropathy. Benign mass lesions of the TMJ include fibrous dysplasia, synovial chondromatosis and osteochondritis dessicans. Malignant primary and secondary mass lesions include osteosarcoma, chondrosarcoma, synovial sarcoma, squamous cell carcinoma, skull base giant cell tumor and secondary parotid tumors. In each category representative images of pathology with key radiologic findings and descriptions will be provided.
Summary/Conclusion
The wide spectrum of disease and imaging findings in the temporomandibular joint are reviewed in this pictorial review. Familiarity with the various entities is important to appropriate management.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

KEYWORDS: TMJ, Temporomandibular

eEdE-92

Imaging of Atypical Orbital Varices: Utilization of Contrast-Enhanced MR Angiography and Valsalva for Differentiation from Other Enhancing Orbital Lesions

Thompson, A. F.·Gentry, L. R.·Hartman, M. J.·Kennedy, T. A.·Lucarelli, M. J.·Reede, D. L.·Smoker, W. R. K.·Turski, P. A.
University of Wisconsin
Madison, WI.

Purpose
The imaging diagnosis of orbital varices is usually straightforward. This exhibit will demonstrate 10 orbital varices with atypical presentations where conventional imaging findings were not completely specific. The prospective utilization of a comprehensive MR imaging (MRI)/MR angiography (MRA) vascular mass protocol (VMP) was helpful in differentiating these atypical varices from other vascular orbital lesions. Many of these atypical cases presented with either loss of vision or cranial neuropathy, both of which are unusual with simple varices. Our goal is to highlight atypical clinical and imaging presentations of orbital varices and the distinguishing VMP features as compared to other avidly enhancing orbital masses.
Approach/Methods
The context will be set briefly by describing both the embryology and classification of vascular malformations as they relate to orbital varices. Ten cases will be used to illustrate the variable clinical presentations, visual complications, and types of disease progression associated with these lesions. The cases will illustrate the widely atypical forms of orbital varices on VMP imaging and the imaging features that distinguish them from other avidly enhancing orbital lesions. Finally, given the variable appearances of orbital varices and their ability to mimic many other enhancing orbital lesions, we will highlight the invaluable use of contrast-enhanced MRA (CE MRA) in differentiating orbital varices from other masses. Flow patterns on CE MRA, lesion distension with valsalva, or demonstration of intralesional thrombus all may be necessary for making the correct diagnosis. Not all features will be present for any given case, however.
Findings/Discussion
The long accepted criterion used to confidently diagnose orbital varices has been a change in lesion size on contrast-enhanced CT or MRI before and after valsava. As we will demonstrate, however, not all varices are distensible, and those that are can lose distensibility at any time in their course for no apparent reason. Contrast-enhanced MRA, on the other hand, may show pulsatile venous phase filling in these cases. Furthermore, this CE MRA appearance is markedly different from that of other avidly enhancing lesions in the differential diagnosis (meningioma, cavernous malformation, nerve sheath tumor, metastasis, hemangiopericytoma).
Summary/Conclusion
Orbital varices have a highly variable imaging appearance and also may demonstrate an atypical clinical presentation that may mimic other avidly enhancing orbital masses. Furthermore, the classical feature of orbital varices, their distensibility, is not always present. As such, these atypical varices are not always differentiated easily from other enhancing orbital lesions by standard imaging techniques. A comprehensive vascular mass protocol consisting of conventional pre and postcontrast MRI, CE MRA, and demonstration of lesion distensibility often is necessary to differentiate atypical orbital varices from other lesions when other conventional imaging is ambiguous.

eEdE-93

MR Imaging Classification of Primary Choroidal Melanoma Using Surface Coil Technique and Imaging Features

Hanagandi, P. B.[1]·Gonçalves, F. G.[2]·Chong, J.[1]·Torres, C. I.[1]·Chankowsky, J.[1]·del Carpio, R.[1]
[1]Montreal General Hospital, McGill University, Montreal, QC, CANADA, [2]Radiologia Infinita - Brasilia Children's Hospital - Brazil, Brasilia, BRAZIL.

Purpose
1. To review and classify primary choroidal melanoma and emphasize the importance of dedicated surface coil imaging. 2. Illustrate various intraocular complications associated with choroidal melanoma.
Approach/Methods
Fifty patients were evaluated with 1.5T MR imaging (MRI) (GE Signa Excite) using a dedicated 3-inch surface coil, T1-weighted,T2-weighted and postcontrast fat-suppressed sequences were used for assessment. Depending on the degree of melanin content, most melanomas demonstrated T1 and T2 shortening. Postcontrast fat-suppressed technique plays a vital role in differentiating primary tumor from retinal detachment, subchoroidal effusion, vitreous hemorrhage and scleral invasion.
Findings/Discussion
Ultrasound is the most widely used imaging modality for the assessment of intraocular tumors. In recent years MRI has emerged successfully as a very promising tool particularly in the assessment of primary choroidal melanoma. Combination of dedicated surface coil imaging and thin slice acquisition generates high signal-to-noise ratio images thereby improving diagnostic accuracy. Ultrasound continues to remain an operator-dependent modality and subtle lesions may be overlooked or misinterpreted. We classified melanomas based on their morphology and location using multiplanar imaging which helps in accurate localization and effective radiotherapy planning and assessment of post-treatment response.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Summary/Conclusion
We have attempted to classify melanomas based on their morphology and location which may help in radiotherapy planning and assessment of post-treatment response. Postcontrast images help in differentiating primary tumor from effusion, hemorrhage and scleral invasion. Lack of operator dependency reduces intra and interobserver discrepancies when measuring tumor burden.

KEYWORDS: 1.5T, Orbits, choroidal melanoma, surface coil imaging

eEdE-94

A Review of Differential Diagnosis of Restricted Diffusion in the Optic Nerves

Maralani, P. J.[1]·Mohan, S.[1]·Srinivasan, A.[2]·Arastoo Vossough, A.[1]
[1]University of Pennsylvania, Philadelphia, PA, [2]University of Michigan, Ann Arbor, MI.

Purpose
Restricted diffusion (RD) in the optic nerves (ON) is an uncommon finding, but when present, it can be helpful in narrowing the differential diagnosis during image interpretation. In addition to dedicated orbital MRI, this finding often can be assessed on routine brain MR imaging. In this exhibit we will review various etiologies and differential diagnosis of RD in the ONs.
Approach/Methods
The ONs are extensions of the brain into the orbits and attention to this fact will facilitate the understanding that similar pathologic processes producing RD in the brain can cause RD in the ONs. In this exhibit we will review: • The arterial supply and venous drainage of the ONs. • Various etiologies of RD in the ONs in detail and categorize the differential diagnoses into vascular, infectious, inflammatory and neoplastic causes, with case examples provided for each category. • Anterior nonischemic papillitis (ANIP) and its unique features. • Dedicated diffusion protocol pertaining to orbits.
Findings/Discussion
Understanding the vascular supply of the optic nerves is important since various segments of the optic nerve are supplied by different vessels. Details of the vascular supply will be provided in the educational exhibit. From a practical standpoint, the arterial supply can be classified into those supplying the optic nerve head and those supplying the remainder of the optic nerve. The venous drainage is predominantly to the central retinal vein and to a lesser degree to the ophthalmic venous system and cavernous sinus. The various etiologies of RD in the ONs can be categorized as follows: 1. Vascular: Acute ischemia due to arterial emboli, arteritis, or central retinal vein occlusion can cause RD in the ON due to acute ischemia or venous hypertension and venous infarction. Venous infarction shows a more extensive pattern of RD than arterial ischemia. The findings on fundoscopic examination (FE) are different in arterial and venous thrombosis. 2. Inflammatory/infectious: Active inflammation such as acute optic neuritis with or without demyelinating disease can cause RD. It also has been reported in viral infections. Fundoscopic examination can show optic disk edema and/or pallor. 3. Neoplastic: Involvement of the ONs by neoplasms with highly packed cells can cause RD. For example diffuse involvement of the ONs by lymphoma or perineural spread of retinoblastoma along the ONs. Fundoscopic examination shows optic disk edema or a retinal mass with or without hemorrhage. 4. Anterior nonischemic papillitis: This finding can be seen in patients with increased intracranial pressure (ICP) due to neoplasm, hydrocephalus and pseudotumor cerebri, and it resolves as ICP returns to normal. Fundoscopic examination shows optic disk edema and/or pallor.
Summary/Conclusion
Attention to the presence of RD in the optic nerves, the clinical scenario, and ophthalmologic exam can significantly help in narrowing the differential diagnosis of this imaging finding and help provide more accurate image interpretations. The etiologies often are similar to those causing RD in the brain.

KEYWORDS: Restricted diffusion, Optic nerve

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eEdE-95

Imaging of Neuro-Ophthalmology for Neuroradiologists

Tantiwongkosi, B.·Schneider, A.·Yu, F.·Schatz, M.
University of Texas Health Science Center San Antonio
San Antonio, TX.

Purpose
This pictorial review will illustrate the relevant anatomy, function and diseases in neuro-ophthamology that neuroradiologists should know. Radiologic and neuro-ophthalmologic correlation is emphasized.
Approach/Methods
Patients with neuro-ophthalmologic diseases often present with nonspecific symptoms, including eye pain, blurred or double vision, and changes in color perception. There are localizing signs detected on neurologic and ophthalmologic examination that are specific for certain anatomical locations, such as junctional visual field defects in anterior chiasmal syndrome. The neural pathways related to neuro-ophthalmic diseases are complicated, such that some neuroradiologists may find them too time-consuming to understand. However, appreciation for these specific localizing signs tremendously helps the neuroradiologists focus on particular anatomical regions, making image interpretation accurate and meaningful. Furthermore, some lesions have pathognomonic appearances on imaging, making further investigation or biopsy unnecessary. Computed tomography (CT), MRI, neuro-ophthalmologic findings (visual field perimetry, fundoscopic and eye movement exams) and simplified diagrams superimposed on CT/MRI are used to elucidate the anatomy, function, and the disorders themselves.
Findings/Discussion
This presentation covers both the afferent visual pathway and efferent papillary/oculomotor pathway. The anatomy and function of each pathway are illustrated by diagrams of nerve fibers and nuclei on MR images compared with gross anatomy specimens. The afferent visual pathway encompasses structures which perceive, relay, and process visual information: the eyes, optic nerves, optic chiasm, optic tracts, lateral geniculate nuclei, optic radiations, and striate cortex. The efferent pupillary/oculomotor pathway controls pupil size and eye movement: the pretectal region, the medial longitudinal fasciculus, the third, fourth, and sixth cranial nerves/nuclei. Specific neurologic and ophthalmologic signs caused by lesions at each subsite of the pathway are highlighted. Diseases vary by location to include neoplasms, demyelinating diseases, infection, and strokes. Imaging characteristics of each disease and differential diagnostic clues are discussed.
Summary/Conclusion
Familiarity with characteristic clinical and neuroimaging findings of neuro-ophthalmologic disease is invaluable for neuroradiologists in providing accurate diagnoses and management guidance.

KEYWORDS: Visual pathways, Oculomotor, neuro-ophthalmology

eEdE-96

A Web-Based Mobile Application for Learning and Reviewing the Appearance of Orbital Tumors Using a Multimodality Approach

Chorney, E. T.·Amin, V. B.·Sicular, S.·Ward, T. J.·Kadoch, M. A.·Pawha, P. S.
Mount Sinai Medical Center
New York, NY.

Purpose
The purpose of the exhibit is: 1. To provide quick and easy access to a web-based mobile application and reference guide that addresses most of the common orbital tumors as evaluated by modern imaging modalities. 2. To provide a reference tool that addresses the limitations of other online reference tools, which can be cost-prohibitive, require log-ins or registration, lack interactivity, and are often slow to engage the end user. 3. To provide imaging of both the specific and nonspecific imaging features of a given orbital tumor. 4. To provide a novel learning platform that is fully functional using either the internet alone or on most major handheld devices and tablets, which are becoming increasingly important as educational resources for fellows, trainees, and students.
Approach/Methods
All relevant orbital tumors encountered at our institution since 2001 were reviewed for potential inclusion in the exhibit.
Findings/Discussion
The major teaching points of this exhibit are: 1. Reviewing the diagnostic as well as non-specific imaging findings of multiple orbital tumors on modern imaging modalities. 2. Encouraging each user to expand on this review by linking each pathology to important AJNR articles that further discuss that specific pathology. 3. Measuring the success of this electronic educational exhibit by monitoring number of online views and traffic directed towards the supplied AJNR articles.
Summary/Conclusion
A web-based mobile application for learning and reviewing the appearance of orbital tumors using a multimodality approach is presented.

KEYWORDS: Orbital tumor

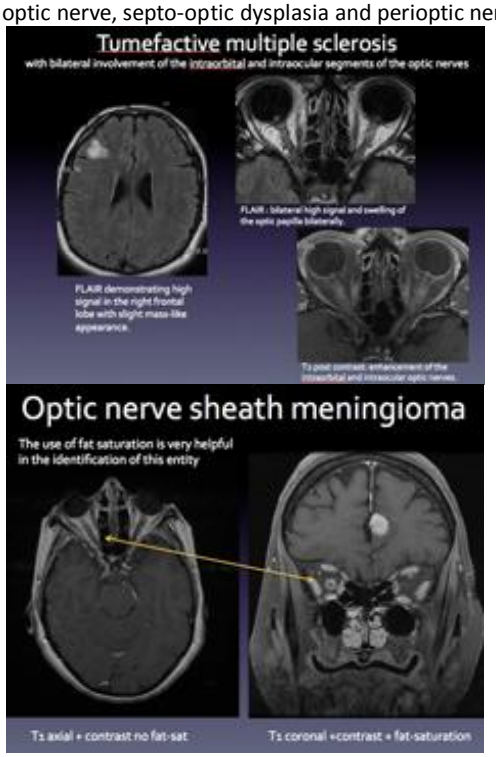
Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eEdE-97

Seeing Is Believing: Optic Nerve Lesions and Their Symptomatology

Chung, R.·Tuan, A.·Dietrich, R.·Dorros, S.·Mafee, M.
University of California San Diego
San Diego, CA.

Purpose
To review the varied pathology of the optic nerve with particular attention paid to the clinical presentation and imaging characteristics.
Approach/Methods
1. Brief review of the normal anatomy of the optic nerve, comparing gross specimens to corresponding CT and MR images. 2. Review of images and symptomatology with quiz format of selected congenital, inflammatory, infectious, and neoplastic conditions of the optic nerve.
Findings/Discussion
Anatomy will be presented in a didactic format. Representative images of selected cases of congenital, inflammatory, infectious, and neoplastic conditions of the optic nerve will be shown with their clinical presentations and salient radiologic points will be made with each image. Each case will be followed by a short quiz to engage the viewer in active participation underscoring important points about clinical diagnosis and management. The following optic nerve lesions will be reviewed: multiple sclerosis of the optic nerve, sarcoidosis, tuberculosis, lymphoma, optic sheath meningioma, optic nerve glioma, metastatic disease to the optic nerve, infarct, hemangioma, neurofibroma, medullary epithelioma of the optic nerve, septo-optic dysplasia and perioptic nerve cyst.



Summary/Conclusion
This educational exhibit will review the varied pathologies of the optic nerve, ranging from the relatively well-known to the exceptional and rare, emphasizing the clinical presentation and imaging characteristics that clinch the diagnosis. After completion of the exhibit, the viewer will have a solid clinical and radiologic understanding of the spectrum of optic nerve lesions to help differentiate between optic nerve pathologies in clinical practice.

KEYWORDS: Optic nerve

eEdE-98

Dual Energy CT Applications for Imaging of the Brain and Neck

Khorrami-Arani, N.[1]·Liang, T.[2]·Shewchuk, J.[1]·Nicolaou, S.[1]
[1]Vancouver General Hospital, Vancouver, BC, CANADA,
[2]University of British Columbia, Vancouver, BC, CANADA.

Purpose
Dual energy CT (DECT) refers to the simultaneous acquisition of low and high voltage CT data (most commonly 80/100 and 140 kVp), and is a technological advancement of CT for which multiple chest and abdominal imaging applications previously have been demonstrated. The purpose of this exhibit is to review the principles of DECT and review and demonstrate examples of potential applications of DECT for imaging of the brain and neck.
Approach/Methods
A retrospective review of patients scanned by the DECT head and DECT neck protocols at our institution will be conducted for imaging examples.
Findings/Discussion
This educational exhibit will review the basic principles and technique behind DECT, and the radiation dose considerations. The exhibit also will review the potential utility of DECT for imaging of the brain and neck. The following applications will be discussed in the exhibit: metal artifact reduction, differentiation between acute intracranial hemorrhage and iodine contrast in patients scanned for stroke and trauma, assessment of iodine distribution in stroke, optimization of kV for CT angiography (CTA), improving detection of acute bleeding (i.e., the dot sign), using iodine color-coded maps, and utility in visualization of the neck vasculature in difficult to assess regions at the base of the skull and heavily calcified vessels. Imaging examples of each of these applications will be demonstrated. In addition, the specific advantages and limitations of these applications of DECT for imaging of the brain and neck will be discussed.
Summary/Conclusion
Recent articles have demonstrated promising results for the application of DECT for imaging of the head and neck. We have demonstrated in our exhibit that DECT can be useful to help reduce metal artifact, differentiate hemorrhage and contrast, assess iodine distribution for

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

stroke imaging, optimize CTA at a lower kV, increase detection of abnormal enhancement with iodine overlay maps, and improve visualization of neck vessels.

KEYWORDS: Dual energy spectral, Dual-energy CT

eEdE-99

Endoscopic versus Transcranial Approaches to Skull Base Tumors: What the Surgeon Wants to Know

Nickell, L. T.·Bhatki, A. M.·Coimbra, C. J.·Saad, A. F.·Gupta, M.·Opatowsky, M. J.
Baylor University Medical Center
Dallas, TX.

Purpose
The purpose of this educational exhibit is to review the imaging characteristics of sinonasal and skull base tumors pertinent to surgical planning, with particular emphasis on the imaging features, extent, and key landmarks critical in determining which lesions can be removed via an endoscopic endonasal surgical approach versus standard open approaches.
Approach/Methods
Using a quiz-based interactive approach, multiple cases of sinonasal and skull base tumors will be presented. The pertinent imaging characteristics and anatomy of each lesion will be reviewed, a differential diagnosis will be generated, and the diagnosis will be revealed. The surgical approach utilized (open transcranial versus endonasal endoscopic) and operative findings then will be discussed, enabling a full understanding of the surgical landmarks and anatomical relationships vital to otolaryngologists and neurosurgeons. Finally, a survey of the endonasal corridors to the skull base will be presented and the advantages of minimally invasive operations, such as the endoscopic endonasal approach, will be reviewed.
Findings/Discussion
The endoscopic endonasal approach is being utilized increasingly to access sinonasal as well as lesions of the skull base, including of the sellar and parasellar regions, anterior skull base, clivus, and petrous region. This surgical approach offers many advantages - the surgical literature describes decreased rates of collateral damage to adjacent neurovascular structures and faster recovery times. There are limitations to this approach, however, and not all skull base tumors can be approached in this manner. It is critical for the neuroradiologist to understand the anatomy of these regions, the characteristics and differential diagnoses of associated tumors, and the anatomical relationships and landmarks that determine if a tumor can be removed en total by an endonasal endoscopic technique. Furthermore, a working knowledge of these surgical techniques is required for accurate assessment of postoperative and longer-term follow-up studies.
Summary/Conclusion
As modern, minimally invasive surgical techniques for sinonasal and skull base tumors become more widespread, it is crucial for the neuroradiologist to have a working knowledge of these procedures and to know what information should be included in the radiology report. A systematic approach to lesions of the sinonasal region and skull base, with special consideration placed on the neurovascular structures and relationships critical to the surgeon, is the key to successful interpretation.

KEYWORDS: Skull base neoplasm

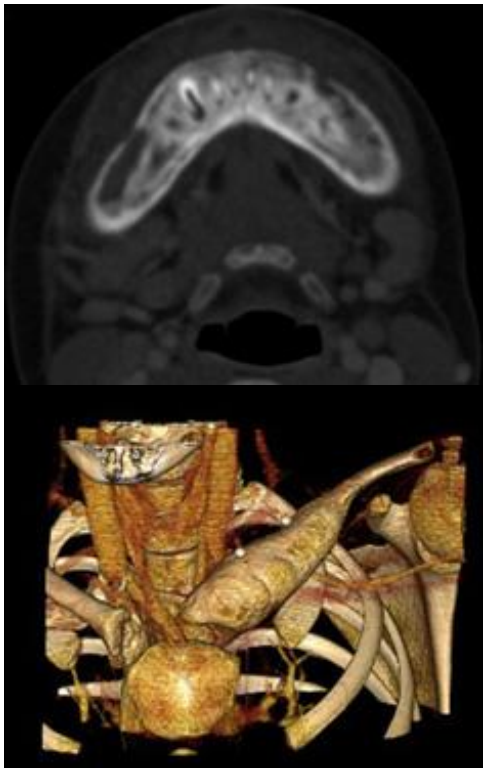
eEdE-100

Head and Neck Imaging of Chronic Recurrent Multifocal Osteomyelitis

Sargar, K.·Kao, S.·Sato, Y.·Singh, A.·Ferguson, P.
University of Iowa Hospitals
Iowa City, IA.

Purpose
1. To demonstrate various imaging features of chronic recurrent multifocal osteomyelitis (CRMO) in head and neck region. 2. To discuss key imaging features to differentiate CRMO from other differential diagnoses such as infection and neoplasms.
Approach/Methods
Chronic recurrent multifocal osteomyelitis is noninfectious osteomyelitis seen in pediatric population. Most common sites of involvement are metaphysis of long bones, clavicle, mandible, vertebrae and pelvis. Typical imaging pattern of involvement in clavicles and mandible is very helpful for the diagnosis of this entity. Though extremity involvement is common in CRMO, involvement of clavicles and mandible is important differentiating point between CRMO and infection. We are demonstrating radiographic,MR imaging (MRI), CT and nuclear scan imaging features of two prototype sites of CRMO (i.e., clavicles and mandibles). There are two phases of CRMO - active and reparative. Imaging appearance also can be helpful to suggest the phase of disease. Lack of abscess, fistula sequestrum and significant soft tissue involvement and aggressive periosteal reaction are key features to differentiate CRMO from infectious osteomyelitis and neoplasms.
Findings/Discussion
Though CRMO is diagnosis of exclusion, radiologists can suggest diagnosis based on imaging appearance. It is necessary to differentiate CRMO from infections and neoplasms as treatment approach and prognosis is entirely different.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Summary/Conclusion
Chronic recurrent multifocal osteomyelitis is noninfectious osteomyelitis in pediatric population with typical involvement of clavicles and mandibles in head and neck region. Various key features on imaging of head and neck region are helpful to differentiate CRMO from infection and neoplasms. Differentiation of CRMO from these entities is essential in view of treatment and prognostication.

KEYWORDS: Head and neck, Osteomyelitis, chronic recurrent multifocal osteomyelitis

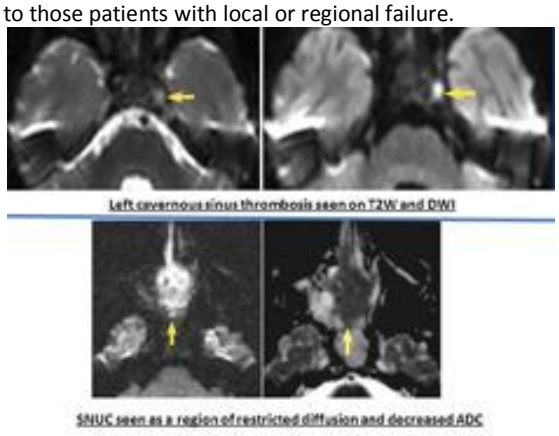
Different Flavors of Advanced Imaging in the Head and Neck

Godfrey, W.·Brown, P. A.·Parmar, H.·Srinivasan, A.
University of Michigan Health System
Ann Arbor, MI.

Purpose
1. To briefly describe the principles of diffusion-weighted imaging (DWI) and perfusion imaging. 2. To illustrate with examples various clinical applications of DWI and perfusion in the head and neck.
Approach/Methods
Content organization: DWI: Principle. DWI: Technique in the head and neck. DWI: Clinical applications: • Differentiation of benign and malignant lesions. • Differentiation of recurrent malignancy and benign granulation tissues. • Identification of recurrent cholesteatoma. • Identification of ocular abscess. • Extraocular muscle involvement in thyroid ophthalmopathy. • Extraocular muscle metastases. • Acute optic neuritis. • Traumatic ocular injury. MR Perfusion: Principle. MR Perfusion: Technique in the head and neck. MR Perfusion: Clinical applications. • Differentiation of malignant from nonmalignant lesions. • Differentiation of recurrent tumors from post-therapy changes. • Monitoring and prediction of response to therapy.
Findings/Discussion
Advanced imaging in the head and neck is gaining increasing importance in head and neck radiology and is making inroads into clinical practice. Due to its unique ability to assess water motion at a molecular level, diffusion-weighted imaging (DWI) shows potential in differentiation of benign and malignant tumors, and post-therapy changes versus recurrent tumor (the latter entities show relative restriction of water motion due to their cellularity). In addition to helping determine benign from malignant lesions, apparent diffusion coefficient (ADC) also could be used for treatment followup. Early response to treatment is reflected in an ADC increase in the primary tumor and nodal metastasis; whereas nonresponding lesions tend to reveal only a slight increase or decrease in ADC during followup. Other clinical applications of DWI include recognition of recurrent cholesteatoma and acute optic neuritis amongst others. Along with DWI, MR perfusion imaging has proved promising in head and neck cancer in the differentiation of tumor and normal tissues, and to evaluate response to therapy. Patients who had local disease control following treatment demonstrating significantly increased blood volume and K^{trans} compared to those patients with local or regional failure.



Left cavernous sinus thrombosis seen on T2W and DWI

SNUC seen as a region of restricted diffusion and decreased ADC

Summary/Conclusion
Advanced imaging frequently is being used in the head and neck for a variety of neoplastic and non-neoplastic clinical indications. The radiologist should be aware of its potential to best interpret day-to-day head and neck imaging.

KEYWORDS: Diffusion-weighted imaging, MR perfusion-weighted imaging

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eEdE-102

Dose Reduction Strategies in Head and Neck Imaging

Khorrami-Arani, N.[1]·Liang, T.[2]·Shewchuk, J.[1]·Nicolaou, S.[1]
[1]Vancouver General Hospital, Vancouver, BC, CANADA,
[2]University of British Columbia, Vancouver, BC, CANADA.

Purpose
Recent technologic advances in CT and new dual energy material characterization capabilities allow for dose reduction techniques that do not sacrifice image and diagnostic quality and can help minimize radiation exposure. The purpose of this exhibit is to review the current dose reduction strategies available for head and neck imaging.
Approach/Methods
A retrospective review of head and neck images from patients from our institution will be conducted.
Findings/Discussion
This educational exhibit will discuss dose reduction strategies available for head and neck imaging. The strategies discussed will include minimizing dose to thyroid and lens using tube current modulation, modulation of kVp based on topogram attenuation values, limiting z-overscanning by applying adaptive section collimation, and new iterative reconstruction techniques to help decrease image noise and artifacts and improve spatial resolution. Head and neck imaging examples of these techniques will be demonstrated, and the advantages of the application of each of these dose reduction techniques will be reviewed.
Summary/Conclusion
After reviewing this educational exhibit, the reader will be able to apply dose reduction techniques to minimize radiation exposure in head and neck imaging. Techniques such as iterative reconstruction, KV modulation, tube current modulation, and adaptive section collimation allow dose reduction in head and neck imaging while maintaining image quality and diagnostic performance.

KEYWORDS: Dose reduction

Cranial Nerve Quiz Module: An Interactive Review of Cranial Nerve Imaging

Perni, K.·Parmar, H.·Ibrahim, M.·Mukherji, S. K.
University of Michigan
Ann Arbor, MI.

Purpose
Imaging of the cranial nerves is challenging due to the complex anatomy, as well the diversity of pathologic processes. It is important for neuroradiologists to understand the basic anatomy of the cranial nerves from the brainstem to their distal branches, firstly to correctly image them and secondly to understand the varied pathologies involving them. In addition, awareness of the clinical findings is important in this setting to guide image interpretation, to determine extent of disease, and subsequently to determine the range of treatment options. This electronic education exhibit is dedicated to demonstrating a critical anatomy of the cranial nerves and varied pathologies. This will be in an interactive way for the user to assess their own knowledge to facilitate long term retention of this information.
Approach/Methods
A retrospective review of the imaging findings in patients with both representative and unusual cranial nerve pathology, correlated with clinical symptomatology, was done using imaging studies of patients conducted at our institution. Modalities demonstrated include both MRI and CT imaging as appropriate in selected cases to best show cranial nerve pathology. In addition, interrogation of the patient's clinical record was performed to outline signs and symptoms pertinent to the imaging study. We observed that we could use the high resolution osseous detail provided by CT of the specific foramina and canals traversed by the various cranial nerves and their branches, combined with the soft tissue resolution of MRI, to demonstrate several different disease processes.
Findings/Discussion
Specific MRI findings such as signal abnormalities on T1- and T2-weight sequences, pattern, distribution and symmetry of contrast enhancement, and cranial nerve morphology proved beneficial for diagnosis, as well as classic CT signs such as expansion of skull base foramina and canals, and effacement of foraminal fat. The utilization of multiplanar MRI sequences and reformatted CT imaging in the coronal and sagittal plane also was important to elucidate complex anatomy and pathology that may be difficult to fully appreciate on axial images alone. Several different imaging sequences, including the use of fat suppressed and high resolution images proved to be very helpful as well. The clinical history was also extremely useful; such vital details included a history of primary malignancy, systemic or localized inflammatory processes, the duration of the patient's symptoms, and their specific focal neurologic deficits. In this exhibit we outlined the clinical presentation in combination with representative sequences and slices on MRI and CT of routine and unusual cranial nerve pathology, in order to help the user formulate a reasonable differential diagnosis.
Summary/Conclusion
There are a large number of specific structures and a wide variety of pathology involving the cranial nerves. Correlation with clinical symptoms, along with an interactive review of the anatomy and disease processes will help the user consolidate his or her knowledge, and apply this to clinical practice. This then could improve the referring physician's ability to adequately determine the extent of disease and develop strategies for further workup and treatment.

KEYWORDS: Cranial nerve palsy

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

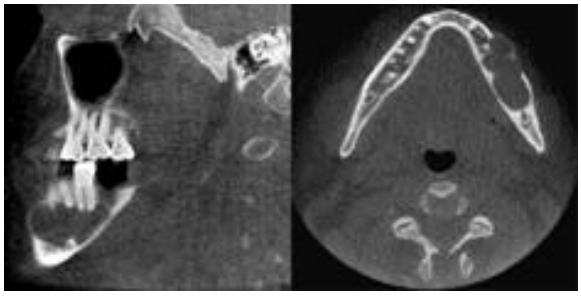
Cone Beam CT: Imaging Techniques and Evaluation of Oral Pathology

Saad, A. F.[1]·Nickell, L. T.[1]·Benson, B. W.[2]·Flint, D. J.[2]·Liang, H.[2]·Opatowsky, M. J.[1]
[1]Baylor University Medical Center, Dallas, TX, [2]Texas A&M Health Science Center - Baylor College of Dentistry, Dallas, TX.

Purpose
The purpose of this educational exhibit is to present current technology and applications of cone beam computed tomography (CBCT) as well as review a spectrum of oral pathology evaluated with CBCT.
Approach/Methods
The principles of image generation and optimization using CBCT will be discussed with particular consideration of CBCT strengths and limitations compared with multidetector computed tomography (MDCT). Frequently encountered oral pathology will be reviewed to illustrate the clinical utility of current CBCT devices. The developing applications and limitations of CBCT in head and neck radiology will be addressed.
Findings/Discussion
Cone beam computed tomography is an emerging technology that has been used increasingly in dentomaxillofacial radiology. Images are created using an x-ray beam collimated with conical geometry and a flat panel detector. In contrast to conventional CT, where z-axis translation is needed to create an image set of multiple axial sections, CBCT requires one gantry rotation to obtain a volumetric dataset consisting of isometric voxels capable of submillimeter resolution. CBCT images can be reconstructed in any plane with theoretically reduced effects of partial volume averaging and improved spatial resolution. Additional strengths include decreased radiation dose and cost when compared to MDCT. CBCT does suffer from increased scatter and image noise, particularly at the periphery of images. Compared with MDCT, the primary limitation in the use of CBCT in diagnostic imaging is less robust characterization of soft tissue density structures. Review of literature generally shows a trend of increased utility of CBCT in the setting of treatment planning, intraoperative guidance, and lesion followup with decreased patient radiation dose. CBCT has been shown to be advantageous in the resolution and identification of small anatomical structures as compared with MDCT. CBCT is well suited to the evaluation of oral pathology; particularly with the availability, cost, and convenience of office-based systems. The evaluation of osseous and dental lesions is optimized due to the inherent high contrast of these structures. The decreased streak artifact obtained with CBCT is advantageous in evaluating lesions adjacent to dental amalgam.



Summary/Conclusion
The utility of CBCT in dentomaxillofacial imaging has been established, with excellent evaluation and characterization of dental disease, jaw lesions, facial trauma, and dental implantology. Emerging applications of CBCT in head and neck radiology include skull base, temporal bone, and sinonasal imaging. The combination of increased spatial resolution with diminished patient radiation dose will be key factors in further applying CBCT to the broader field of neuroradiology.

eEdE-105

Lytic Lesions of the Mandible and Maxilla: Imaging with Surgical Correlation

Cambron, S. C.·Addante, R. R.·McIntyre, J. J.
Dartmouth Hitchock Medical Center
Lebanon, NH.

Purpose
Lytic lesions of the mandible and maxilla present a common differential challenge, yet is infrequently taught in medical school or residencies. Although neuroradiologists often are presented with these lesions at CT, exposure to these lesions appearance on plan radiographs and surgical findings are limited. Our aim is to present the anatomy, imaging, and surgical findings of lytic lesions of the mandible and maxilla through an interactive series of cases with plain radiographs, CT, and intraoperative surgical images.
Approach/Methods
We review the imaging of lytic mandibular and maxillary lesions acquired at our institution with correlative surgical images acquired over a 7-year period. Findings are presented in an interactive electronic PowerPoint based format.
Findings/Discussion
The differential considerations of lytic lesions of the mandible and maxilla are presented. Images and illustrations of relevant anatomy including tooth and osseous structures, alveolar nerve, and sinuses will be reviewed. Specific images will be used to illustrate key differential features which can narrow the diagnosis including location relative to the teeth (periapical,

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

periconal, interradicular), alveolar nerve, and solitary lesions. There also will be a discussion of lesion features such as degree of loculation, border definition, and matrix generation. Interactive features are included which allow participants to click on a location or lesion feature to bring up differential cases based on that location or feature. A summary of key teaching points also is included.
Summary/Conclusion
Lytic lesions of the mandible and maxilla present an interesting differential challenge. With an understanding of relevant anatomy and differential considerations we can accurately diagnose the etiology of these lesions and guide treatment decisions to improve patient care.

Clival Tumors and Mimics: When It's Not a Chordoma

Noor, A.·Doshi, A.·Corcuera-Solano, I.·Fowkes, M.·Well, D.·Patel, K.·Pawha, P.·Nadich, T.·Som, P.
Mount Sinai Hospital
New York, NY.

Purpose
There are a variety of both common and uncommon lesions that can involve the clivus. A number of these entities have similar and often overlapping imaging appearances. The purpose of this exhibit is to review the imaging features of these lesions and provide a succinct differential diagnosis.
Approach/Methods
A retrospective review of our imaging cases of different clival lesions that had pathologic correlation was performed. Between 2010 and the present time, 10 cases were identified.
Findings/Discussion
In this group of patients the clinical presentations often were noncontributory to diagnosis. Symptomatology included headache, localized pain or in the case of pituitary lesions, pituitary-axis dysfunction. Therefore, imaging has become an important tool in differentiating these entities. Benign and malignant tumors involving the clivus often are difficult to differentiate as many of these lesions have overlapping features on CT and MRI. Location, local bony changes, signal characteristics and enhancement patterns may allow the radiologist to provide a narrowed differential diagnosis. Sphenoid mucocoele, meningioma, chondrosarcoma, ecchordosis physaliphora, a rare olfactory neuroblastoma, and invasive pituitary adenoma are some of the lesions that can have imaging findings similar to that of a chordoma; however, they are quite different in their treatment and prognosis. In this exhibit, the imaging appearance and underlying pathology of these entities will be reviewed. The imaging features that permit some distinction between these diagnoses will be emphasized.
Summary/Conclusion
Clinical presentations of patients with lesions in the clivus often are not helpful in identifying an underlying pathology. Imaging has become a very important tool. Because there are overlapping imaging features for many of these entities, arising at a pertinent and limited differential diagnosis is of utmost importance to the ordering clinician.

KEYWORDS: Chordoma, Clivus

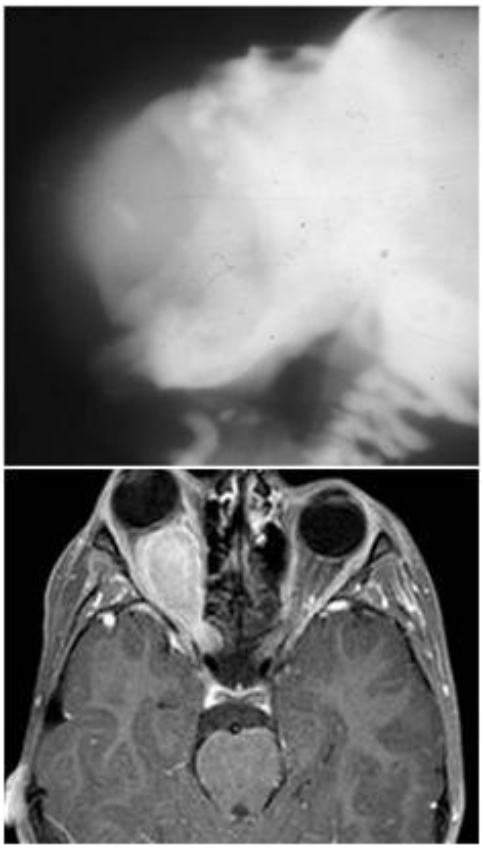
eEdE-107

A Review of Benign and Malignant Pediatric Head and Neck Masses

Meesa, I.·Parmar, H.·Ibrahim, M.·Mukherji, S.
University of Michigan
Ann Arbor, MI.

Purpose
A broad spectrum of congenital and acquired solid and cystic masses can be encountered in the pediatric head and neck. Although most masses have a benign etiology, it is important for the radiologist to be apprised of potential malignant lesions, especially in the appropriate clinical context. The purpose of this poster is to describe and illustrate US, CT and MR imaging findings of various common/rare and benign/malignant pediatric head and neck masses encountered at our institution, followed by a brief presentation of the pathophysiology. Pertinent embryology for certain congenital lesions will be described, if relevant.
Approach/Methods
A retrospective review of pediatric head and neck masses encountered at our institution on US, CT, and MRI over the last 10 years will be performed. IRB approval was obtained.
Findings/Discussion
In this exhibit, we will classify common pediatric head and neck lesions into the following broad categories: orbits, nasal region lesions, salivary, thyroid, lymph node, nerve sheath, vascular, muscle and miscellaneous. Listed below are some of the common lesions we will present in each category: Orbits (gliomas, meningiomas), Nasal region masses (encephaloceles, nasal gliomas, dermoids-epidermoids, hemangiomas), maxillary/mandibular lesions (ameloblastoma), Nerve Sheath tumors [schwannoma (NF2), plexiform neurofibroma (NF1)], Salivary lesions (rannulas), Thyroid lesions (nodules, adenomas, colloid cysts, papillary carcinoma), Lymph nodes (inflammatory, infectious, lymphoma, metastases, Vascular [congenital hemangiomas, arteriovenous malformation, lymphangiomas, venous malformations vs acquired (aneurysm, thrombosis)], Muscle (fibromatosis coli, aggressive fibromatosis, rhabdomyosarcoma), and Miscellaneous [congenital anomalies of branchial apparatus, thyroglossal duct cyst, thymic cyst, teratomas/dermoid, glomus tumors (glomus jugulare), cervical lipoblastoma, cervical encephalocele].

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Summary/Conclusion
After reviewing the exhibit, the reader will have a better appreciation/understanding of the various pediatric head and neck tumors one might come across while reviewing/interpreting pediatric neuroimaging studies.

eEdE-109

Pseudotumors and Uncommon Lesions of the Infrahyoid Neck: How to Avoid Misinterpretation and Pitfalls

Noujaim, S.·Abel, N.·Cacciarelli, A.
William Beaumont Hospital
Royal Oak, MI.

Purposezi
Misdiagnosis and mischaracterization of these less common lesions within the infrahyoid neck may lead to unnecessary biopsies, procedures and additional imaging, exposing the patient to unwarranted complications. The purpose of this presentation is to familiarize the readers with the less common lesions and pseudotumors affecting the infrahyoid neck, how to recognize and diagnose them as well as how to narrow the differential diagnosis avoiding pitfalls in interpretation.
Approach/Methods
Numerous cases were collected from the archives of a major tertiary medical center. The best cases were reviewed and selected for purpose of this presentation. The cases presented here include but are not limited to congenital anomalies related to 3rd and 4th branchial apparatus (thymopharyngeal duct cyst, ectopic thymus, 4th branchial sinus tract and related thyroid abscess), pathology related to the brachial plexus (primary and metastatic tumors and hypertrophic neuropathies), lesions and pseudolesions of the neck muscles (levator claviculae muscle, hypertrophy of levator scapulae muscle, fibromatosis coli of newborn, calcific tendonitis of the longus coli muscle), foregut anomalies (foregut duplication cysts) and other congenital anomalies (dermoid cyst and teratomas).
Findings/Discussion
After a brief review and definition of the infrahyoid spaces of the neck using diagrams and illustrations, a number of less common lesions will be presented along with its differential diagnosis.
Summary/Conclusion
Misdiagnosis and mischaracterization of these less common lesions and pseudotumors within the infrahyoid neck may lead to unnecessary biopsies, procedures and additional imaging, exposing the patient to unwarranted complications.

KEYWORDS: Neck lesions, Congenital, tumor

eEdE-110

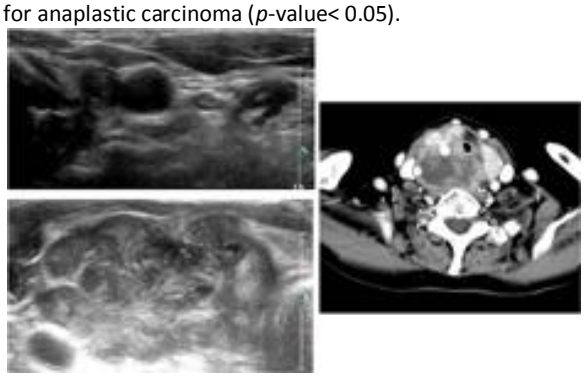
Imaging Features of Anaplastic Thyroid Carcinoma: An Unfamiliar Entity in Fatal Neoplasm. What's the Role of US and CT in Anaplastic Thyroid Carcinoma Patients?

Lee, A.·Kim, J.
Seoul National University Hospital
Seoul, KOREA, REPUBLIC OF.

Purpose
1. To present typical ultrasonographic (US) and computed tomographic (CT) features of anaplastic carcinoma. 2. To determine if useful imaging features of anaplastic carcinoma can predict prognosis.
Approach/Methods
We retrospectively reviewed the imaging and medical records of the 36 patients (9 men and 27 women) among 50 patients diagnosed with ATC from August 1995 to November 2011 at our hospital. Image analysis was performed according to the following US and CT parameters: size, echogenecity on US, presence of necrosis/calcification, perithyroidal invasion, lymph node (LN) metastasis and distant metastasis. Clinical data were sex, age, method for diagnosing ATC, treatment and survival duration. Statistical analysis (student t-test, Fisher's exact test and uni/multivariant analysis) was used.
Findings/Discussion
The mean age of patient at diagnosis was 61 years (range, 22-88 years). Anaplastic carcinomas appeared as large (average 3.9 cm) masses accompanied by necrosis (61.1%),

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

calcification (91.6%), direct invasion into the adjacent organs (83.3%), and cervical lymph node involvement (77.8%) on US and CT. All lesions were shown as hypo/marked hypo-echoic mass on US. Multivariant analysis identified patient age (>70 years), tumor size, and extrathyroidal invasion as statistically significant predictors for anaplastic carcinoma (*p*-value< 0.05).



Summary/Conclusion
If an older patient has a large hypoechogenic thyroid mass with necrosis, calcification and extrathyroidal invasion, anaplastic carcinoma should be included in the differential diagnosis. Ultrasound and CT features also help to predict the prognosis of patients.

KEYWORDS: Thyroid, Carcinoma, anaplastic thyroid carcinoma

eEdE-111

Imaging Spectrum of Blunt Vascular Neck Injuries

Khorrami-Arani, N.[1]·Liang, T.[2]·Shewchuk, J.[1]·Nicolaou, S.[1]
[1]Vancouver General Hospital, Vancouver, BC, CANADA, [2]University of British Columbia, Vancouver, BC, CANADA.

Purpose
Blunt vascular neck injuries (BVNI) encompass injuries to the carotid and vertebral arteries, which can occur in the setting of polytrauma or injury to the craniocervical region. Although previously thought to be rare, recent literature has reported an incidence of up to 1.60% of injuries in blunt trauma patients. Complications such as stroke or cerebrovascular ischemia are a common cause of morbidity and mortality in BVNI and can appear 10-72 hours post-trauma after a latent phase. Thus, early detection and management of these injuries is crucial. The purpose of this exhibit is to review the utility of screening, discuss the imaging modalities available with emphasis on dose reduction and new imaging techniques, and review the grading and characteristic findings of BVNI and impact on therapeutic strategies.
Approach/Methods
A retrospective review of BVNI at our institution will be conducted for imaging examples to demonstrate the spectrum of these injuries.
Findings/Discussion
This educational exhibit will review the epidemiology, mechanism of injury, and clinical presentation and assessment of BVNI. The rationale of a potential screening algorithm involving multidetector CT (MDCT) will be discussed. Imaging modalities for BVNI including ultrasound, MR angiography, CT angiography, and catheter angiography will be reviewed. The spectrum of injuries and the injury grading system of BVNI on MDCT will be discussed with imaging examples. Imaging mimics and diagnostic pitfalls will be discussed and demonstrated to help readers avoid these diagnostic errors. This exhibit will show the utility of new artifact minimization and dose reduction techniques such as iterative reconstruction and dual energy imaging, particularly for vessels within the skull base and foramina transversaria, which are difficult regions to assess. Follow-up imaging, prognosis, and management will be reviewed. An imaging algorithm will be introduced for screening of BVNI and impact on treatment strategies such as when medical versus interventional/surgical management is required.
Summary/Conclusion
Blunt vascular neck injuries are associated with significant morbidity and mortality that may be prevented by early screening with MDCT. The imaging spectrum of BVNI and its mimics have been demonstrated in this exhibit. Prognosis and management is based on grading of BVNI. New artifact minimization and dose reduction techniques are useful for optimal diagnostic imaging of BNVI.

KEYWORDS: CTA, vascular neck injuries

Role of CT and MR Imaging in Thyroid Cancer Patients: Who and When to Image, and Where to Look

Saito, N.[1]·Nakahira, M.[1]·Chang, Y.[2]·Sakai, O.[2]·Uchino, A.[1]·Kimura, F.[1]
[1]Saitama International Medical Center, Saitama, JAPAN, [2]Boston Medical Center, Boston University School of Medicine, Boston, MA.

Purpose
The purpose of this educational exhibit is: 1) To understand the role of CT and MR imaging in assessment of thyroid cancer. 2) To review various radiographic manifestations of thyroid cancer and potential pitfalls.
Approach/Methods
We retrospectively reviewed our patient database to identify patients with thyroid cancer. CT and MR imaging studies and clinical history were examined. Through illustrative case examples, we will demonstrate the clinical utility of CT and MR imaging for thyroid cancer.
Findings/Discussion
Evaluation of thyroid disease often is performed with ultrasound or nuclear medicine. Although it is difficult to reliably distinguish between benign and malignant lesions on CT and MR imaging, these modalities play highly important roles in the staging and treatment of thyroid

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

cancer. The clinical utility of CT and MR imaging are: (A) evaluation of tumor burden and invasion to the adjacent structures, (B) assessment of lymph nodes, (C) assessment of distant metastasis, (D) differentiation of thyroid lesion from other pathologic lesions, (E) presurgical anatomical evaluation, and (F) posttreatment evaluation. Various characteristic imaging findings are reviewed and the indications for CT and MR imaging in the patients with thyroid cancer are discussed. The limitations of CT and MR imaging for thyroid lesions also are discussed.
Summary/Conclusion
The teaching points of this exhibit are: 1) CT and MR imaging can be helpful in making accurate diagnosis and surgical planning in patients with thyroid cancer, particularly in cases of bulky disease or tumor invasion resulting in symptoms such as hoarseness, difficulty of breathing and dysphagia. 2) Knowing who and when to image with CT and MR in the setting of thyroid cancer and recognizing the potential pitfalls is critical for accurate diagnosis.

KEYWORDS: Thyroid, CT, MR imaging

eEdE-113

Imaging Spectrum and Management of Penetrating Neck Trauma

Khorrami-Arani, N.[1]·Liang, T.[2]·Shewchuk, J.[1]·Nicolaou, S.[1]
[1]Vancouver General Hospital, Vancouver, BC, CANADA, [2]University of British Columbia, Vancouver, BC, CANADA.

Purpose
Penetrating neck injuries are associated with a high risk of clinically significant injury due to the presence of multiple vital structures within a small anatomical area. The mortality from penetrating neck injuries has been estimated to be up to 10%. Imaging allows for early diagnosis and can assist in management decisions for these injuries. The purpose of this exhibit is to review the mechanisms of penetrating neck trauma, available imaging modalities, characteristic findings on multidetector CT (MDCT), and the utility of MDCT for determination of surgical versus nonoperative management.
Approach/Methods
A retrospective review of cases of penetrating neck injuries from our institution will be conducted.
Findings/Discussion
This educational exhibit will review the anatomy, mechanism of injury, and clinical assessment of penetrating neck injuries to the neck. A review of the anatomical zones of the neck with correlation to imaging and implications for management will be conducted. Imaging modalities including ultrasound, angiography, MRI, and multidetector CT will be assessed for use in penetrating neck injuries. Imaging examples and MDCT characteristics will be reviewed for specific penetrating injuries, including arterial, venous, esophageal, tracheal, and laryngeal injuries. The utility of new techniques such as iterative reconstruction and mono-energetic spectral imaging for metal artifact reduction on CT will be reviewed. The usefulness and limitations of MDCT to determine wound trajectory and to guide appropriate intervention (surgical versus nonoperative) will be discussed. Our institution's protocol for imaging penetrating neck injuries will be described.
Summary/Conclusion
After reviewing this exhibit, the reader will understand the characteristic imaging findings and have reviewed imaging examples of various patterns of penetrating neck injury. Dose reduction and artifact minimization techniques can help minimize metal artifacts and can help limit radiation dose exposure to patients. Multidetector CT is useful in guiding appropriate management (surgical versus nonoperative).

eEdE-114

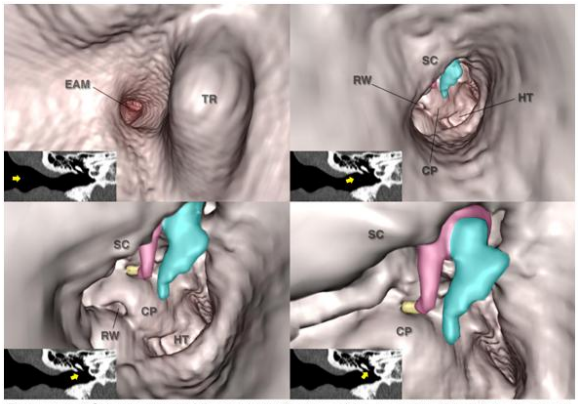
A Walking Tour of the Temporal Bone

Byrns, K.·Lev, S.
Nassau University Medical Center
East Meadow, NY.

Purpose
We provide the viewer with a virtual tour through the intricate architecture of the temporal bone, stopping along the way to examine areas of physiologic and pathologic interest, utilizing three-dimensional reformations of high-resolution MDCT studies.
Approach/Methods
High-resolution axial sections were obtained via 320-slice multidetector computed tomography. Vital Vitrea fx software was utilized to generate volumetric and flythrough reformations of the temporal bone in order to elucidate the complex anatomy. The anatomical review is supplemented by cases of traumatic and nontraumatic pathology from our community-based Level 1 trauma center. The images were postprocessed in Adobe Photoshop to provide colorization and labeling for further illustration.
Findings/Discussion
The temporal bone represents one of the most intricate regions of head and neck imaging, featuring complex and subtle anatomical details. It is crucial for the radiologist to properly orient him or herself and, in doing so, develop region-appropriate differential diagnoses. The ability to obtain thin collimation images via state-of-the-art multidetector computed tomography has proven invaluable for unlocking the elaborate three-dimensional relationships of the various key regions and associated structures. Furthermore, volumetric rendering software has enabled the radiologist to observe the anatomy in novel ways. In particular, virtual flythrough software can transform an area several orders of magnitude smaller than the observer into an environment to be explored. The

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

journey begins at the entrance, the external auditory canal, which may be afflicted by various degrees of atresia as well as infectious and neoplastic processes, both benign and malignant. We then proceed into the middle ear, with its various recesses and prominences, housing the ossicular chain. The ossicles demand careful observation in order to detect improper development, erosive neoplasms, or disruption from longitudinal fractures. Gazing upward reveals Prussak's space, the classic location for an acquired cholesteatoma. Next, we transport the viewer into the inner ear, with its cochlear turns and labyrinthine chambers, observing the myriad congenital and acquired lesions that one might encounter. If one finds the structure unexpectedly simplified, the diagnosis lies along a spectrum extending from aplasia to incomplete partition, such as the Mondini deformity. Finally, the voyage culminates as we exit through the porus acusticus and vestibular aqueduct, where entities such as vestibular schwannomas or endolymphatic sac tumors may be encountered.



Flythrough of Outer Ear into Middle Ear highlighting the ossicles, the malleus (blue), incus (magenta), and stapes (yellow), as well as additional areas of interest, including the external acoustic meatus (EAM), tragus (TR), round window niche (RW), hypotympanum (HT), scutum (SC), and cochlear promontory (CP). The perspective of each panel is indicated by the arrow within the inset coronal CT images.

Summary/Conclusion
Virtual flythrough reconstructions provide a unique and powerful method to understand and appreciate the exquisite anatomy of the temporal bone and facilitate location-based differential diagnoses.

The Preoperative Cholesteatoma: Beyond the Scutum and Prussak Space. Identification of Surgical Landmarks and Anatomical Variants that Could Have Implications on Surgical Method and Approach

Hakham, S.·Sillman, J.·Madan, N.·Bedi, H. S.
Tufts Medical Center
Boston, MA.

Purpose
1. Review the surgical anatomy of the ear, with CT correlation. 2. Identify landmarks within the temporal bone that radiologists should be familiar which could have implications on surgical approach. 3. Describe variants within the temporal bone which could have implications on the type of surgery and surgical approach.
Approach/Methods
The anatomical landmarks of the ear and temporal bone are reviewed in the order in which the structures are approached during surgery. Other surgically relevant details including anatomical variations and associated surgical complications are presented in pictorial and tabulated formats, where appropriate.
Findings/Discussion
Multiplanar high-resolution computed tomography (HRCT) is the reference standard for imaging examination of the temporal bone, providing the surgeon with a precise three-dimensional road map in preoperative evaluation of cholesteatoma. This examination has a crucial role on the specific surgical approach adopted by the surgeon and subsequently on the clinical outcome to reduce and potentially prevent intra and postoperative complications. A thorough knowledge of the surgical anatomy and pathology by the expert radiologist not only aids in adequate interpretation of such studies, but also aims the surgeon to avoid the unnecessary complications. Through a collaborative effort with otolaryngologists at our institution, we propose a comprehensive, yet systematic method for evaluation of the temporal bone, pointing out the essential components of an ideal dictation in preoperative evaluation of cholesteatoma.
Summary/Conclusion
CT examination of the temporal bone is instrumental in the diagnosis and preoperative evaluation of cholesteatoma. Our exhibit provides a structured format for interpretation of the preoperative cholesteatoma, with special attention to surgical landmarks and anatomical variants that could have implications on surgical method and approach.

KEYWORDS: Cholesteatoma, preoperative evaluation

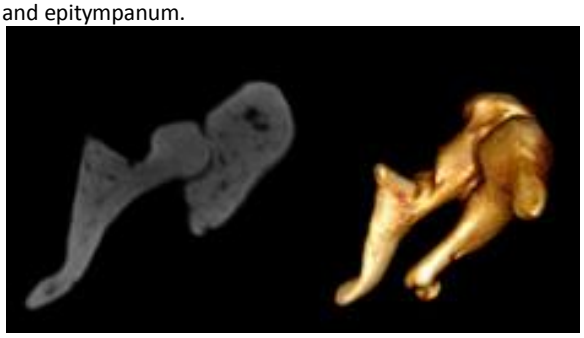
High-Resolution Ossicular Anatomy: Correlation with MicroCT and Otoscopy

Choudhri, A. F.[1,2]·Whitehead, M. T.[1,2]·Chatterjee, A. R.[1]·MacDonald, C. B.[1]
[1]University of Tennessee Health Science Center, Memphis, TN, [2]Le Bonheur Children's Hospital, Memphis, TN.

Purpose
Ossicles are tiny bones within the middle ear critical for conduction of pressure vibrations from the tympanic membrane to the oval window. Congenital and acquired abnormalities of the ossicles can impair hearing; however, due to their small size with features below clinical imaging resolution, a detailed understanding of their morphology can aid in evaluation.
Approach/Methods

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

We obtained 8 micron isotropic resolution microCT scans of individual ossicles, as well as of an entire middle ear with the ossicular chain intact, to help provide a teaching tool about the morphology and orientation of the ossicles. Comparison with clinical CT scans performed at 0.5 mm isotropic resolution is provided, as well as otoscopic images to assist in understanding spatial orientation.
Findings/Discussion
An interactive viewer allows the user to scroll through microCT and clinical CT datasets, and navigate in a virtual 3D environment. This information is paired with detailed photographs of the ossicles and otoscopic images, with the goal of conveying an understanding of the morphology and orientation of the ossicles and their associated ligaments, as well as the margins of the mesotympanum and epitympanum.



Summary/Conclusion
Interpretation of abnormalities in ossicular morphology and articulation requires a detailed understanding of the underlying anatomy. By reviewing the CT and microscopic appearance of the ossicles and their ligaments we feel that the reader will have an improved understanding of the anatomy and spatial orientation of the structures of the mesotympanum.

KEYWORDS: Temporal bone, Anatomy

Views of the Third-Window Phenomenon: What a Radiologist Needs to Know

Torres, F.·Hoque, K.·Lerner, A.·Shiroishi, M.·Go, J. L.
University of Southern California
Los Angeles, CA.

Purpose
To provide an overview of lesions of the inner ear resulting in the third-window phenomenon.
Approach/Methods
Utilizing the teaching files from a major academic institution on the West Coast as well as an associated pre-eminent ototology clinic, the clinical manifestation, pathophysiologic basis, and diagnostic imaging features of lesions resulting in third-window phenomenon will be reviewed.
Findings/Discussion
Fistula formation associated with the inner ear may result in the "third-window" phenomenon. This exhibit will review the pathologic basis and current theories associated with this entity which leads to sensorineural hearing loss. Examples of this entity will be provided utilizing high-resolution CT and MR imaging. Additional reformatted planes of view on CT also will be described to aid the radiologist in making this diagnosis.
Summary/Conclusion
The third-window phenomenon is an uncommon cause for sensorineural hearing loss. A combination of the clinical symptomatology, audiometry examination, and imaging features will be reviewed to aid the radiologist in making this unique diagnosis.

KEYWORDS: Inner ear, Semicircular canal dehiscence, third window

Intratympanic Masses: The Common, the Rare, and the Unheard of

Tuan, A. S.·Chung, R.·Farid, N.·Mafee, M. F.
University of California San Diego
San Diego, CA.

Purpose
The thrust of this exhibition is to review and to differentiate various intratympanic masses in adults and children.
Approach/Methods
The normal intratympanic anatomy will be reviewed, then selective images of pathologic intratympanic entities will be shown. A short quiz will follow to reinforce the concepts in this educational exhibit.
Findings/Discussion
Following a review of normal intratympanic anatomy, selective images of the following entities will be presented. 1. Intratympanic teratoma (choristoma). 2. Intratympanic papilloma and polyps. 3. Intratympanic meningioma (ectopic) and extension of intracranial en plaque meningioma into the middle ear (along vascular, neural, and natural channels). 4. Intratympanic extension of labyrinthine schwannoma. 5. Glomus tympanicum and its mimics (ectopic carotid, jugular bulb diverticulum, cholesterol granuloma, extramedullary hematopoiesis). 6. Primary cholesteatoma of the middle ear. 7. Intratympanic metastasis.
Summary/Conclusion
This educational exhibit will enhance our understanding of various intratympanic masses, emphasize the differing imaging characteristics of intratympanic masses, and increase our ability in differentiating these lesions. Imaging will play an important role in the clinical management of intratympanic lesions.

KEYWORDS: Middle ear, Temporal bone

eEdE-119

Radiologic Evaluation of Congenital Aural Dysplasia: Spectrum and Associated Abnormalities

Nace, S. R.·Kennedy, T. A.·Gubbels, S. P.·Gentry, L. R.
University of Wisconsin
Madison, WI.

Purpose
To present an interactive display exhibiting the spectrum of congenital aural dysplasia as well as the complex cross-sectional anatomy of associated middle ear, mastoid, and inner ear anomalies.
Approach/Methods
Multiple cases of congenital aural dysplasia were collected and reviewed at the University of Wisconsin Hospital and Clinics. Selected high-resolution CT and 3D surface rendered reformatted images illustrate the spectrum of pinna and external auditory canal malformations, in addition to associated abnormalities of the middle ear, mastoid, and inner ear.
Findings/Discussion
Congenital aural dysplasia occurs on a spectrum, ranging from mild deformities resulting in isolated malformation of the pinna to complete absence of the external auditory canal with severe associated middle and inner ear defects. Due to the concurrent embryologic development of the first and second branchial arches, associated abnormalities of the middle ear and mastoid are disproportionately represented. Evaluation of the inner ear, ossicular chain, course of the facial nerve, and degree of development/ pneumatization of the middle ear cavity and mastoid antrum are crucial in preoperative assessment in this patient population. An understanding of these known associations, as well as the complex three-dimensional anatomy of the temporal bone on high-resolution CT is required for full appreciation of the extent of abnormalities beyond the clinically obvious, and those abnormalities which are critical in managing the patient from both clinical and surgical perspectives.
Summary/Conclusion
Radiologic evaluation of congenital aural dysplasia requires an understanding of the disease spectrum, known associated abnormalities due to embryologic origins, and the complex cross-sectional anatomy of the temporal bone on high-resolution CT.

KEYWORDS: Congenital aural atresia, Temporal bone

eEdE-120

A Web-Based Mobile Application for Learning and Reviewing the Appearance of Osseous Lesions of the Skull Using a Multimodality Approach

Cohen, M. G.·Kadoch, M. A.·Sicular, S.·Fitzpatrick, D.·Naidich, T. P.·Rosenberg, H. K.
Mount Sinai Medical Center
New York, NY.

Purpose
The purpose of the exhibit is: 1. To provide quick and easy access to a web-based mobile application and reference guide that addresses most of the common osseous lesions of the skull as evaluated by modern imaging modalities. 2. To provide a reference tool that addresses the limitations of other online reference tools, which can be cost-prohibitive, require log-ins or registration, lack interactivity, and are often slow to engage the end user. 3. To provide imaging of both the specific and nonspecific imaging features of a given osseous skull lesion. 4. To provide a novel learning platform that is fully functional using either the internet alone or on most major handheld devices and tablets, which are becoming increasingly important as educational resources for fellows, trainees, and students.
Approach/Methods
All relevant osseous lesions of the skull encountered at our institution since 2001 were reviewed for potential inclusion in the exhibit.
Findings/Discussion
The major teaching points of this exhibit are: 1. Reviewing the diagnostic as well as nonspecific imaging findings of multiple osseous skull lesions on modern imaging modalities. 2. Encouraging each user to expand on this review by linking each pathology to important AJNR articles that further discuss that specific pathology. 3. Measuring the success of this electronic educational exhibit by monitoring number of online views and traffic directed towards the supplied AJNR articles.
Summary/Conclusion
A web-based mobile application for learning and reviewing the appearance of osseous lesions of the skull using a multimodality approach is presented.

KEYWORDS: Skull, Neoplasm

eEdE-121

Conductive Hearing Loss: Common Etiologies and Key Imaging Features

Torres, F.·Lerner, A.·Shiroishi, M.·Hoque, K.·Go, J.
University of Southern California
Los Angeles, CA.

Purpose
This exhibit will review the characteristic imaging features of the most common etiologies of conductive hearing loss.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Approach/Methods
Case material will be provided from the teaching files from a major academic institution on the west coast and associated pre-eminent ototology clinic. All cases were diagnosed utilizing the Weber-Rinne test and audiometry examination for which they were referred for potential conductive hearing loss without sensorineural hearing loss.
Findings/Discussion
Conductive hearing loss is due to an abnormality of conduction of sound waves to the oval window. This exhibit will examine a wide variety of pathologic processes that result in conductive hearing loss, including otodystrophies associated with the middle ear cavity including fibrous dysplasia and Paget's disease. In addition, primary ossicular anomalies including ossicular fixation and erosive processes will be reviewed, as well as congenital structural abnormalities which may involve the external auditory canal and middle ear cavity. In addition, the imaging features of acquired lesions within the middle ear that may cause impingement of the ossicular chain due to inflammation or infection will be presented, including space-occupying masses within the middle ear cavity that also result in conductive hearing loss.
Summary/Conclusion
Unlike sensorineural hearing loss, for which the cause may not be radiographically imaged, the underlying pathology is commonly determined by closely scrutinizing the external auditory canal, tympanic membrane, and the middle ear cavity and its contents and may be missed by the radiologist. This exhibit will educate the attendee of the imaging features that are the root cause of conductive hearing loss.

KEYWORDS: Conductive hearing loss, Temporal bone

eEdE-122

CT Evaluation of External Auditory Canal Atresia: What the ENT Wants to Know

Hu, J.·Nguyen, V.
North Shore Long Island Jewish Health System
New Hyde Park, NY.

Purpose
CT plays a central role in preoperative evaluation and planning for external auditory canal atresia. This exhibit will present the various findings of external auditory canal atresia and their implications in surgical planning.
Approach/Methods
We will review the CT findings of external auditory canal atresia, discuss imaging findings that may serve as surgical landmines, review the basic mechanism of surgical repair, and highlight the relevant findings that the surgeon uses to plan the surgical approach.
Findings/Discussion
CT is used to evaluate appropriate surgical candidates, and can be predictive of postoperative hearing results. Relevant CT findings include the degree of formation of the incudomalleolar complex, the integrity of the incudostapedial joint, the patency of the oval and round windows, temporal bone pneumatization, the integrity of the stapes, and the course of the facial nerve. Of note, external auditory canal atresia in association with several congenital malformation syndromes may be more severe, involving more middle ear and even inner ear deformities.
Summary/Conclusion
The CT findings of external auditory canal atresia that the radiologist conveys to the surgeon play a vital role in both the determination of appropriate surgical candidates and in preoperative planning.

KEYWORDS: Middle ear, Inner ear, external auditory canal

eEdE-122a

Problematic Pediatric Airway: Prenatal and Postnatal Imaging

Ferrante, M.·Steinklein, J. M.·Bittman, M.·Nguyen, V.
Long Island Jewish Medical Center
New Hyde Park, NY.

Purpose
Airway compromise is a potentially life-threatening condition that necessitates urgent medical attention. The pediatric population is particularly at risk as the pharyngeal and laryngeal spaces are smaller, and can be narrowed at baseline from lymphoid tissue. Narrowing can be due to a multitude of causes which are highlighted in this exhibit.
Approach/Methods
Select cases of airway compromise in the pediatric population have been included for review and educational exhibit, and categorized into congential masses, anomalies, infectious/inflammatory, and foreign bodies. Discussion of each case will follow with take-home points highlighted throughout the presentation. Methods of fetal MRI and the need for multiplanar series will be reviewed. Select cases collected at our institution include: CHAOS syndrome, Cleft palates and oral cavity narrowing, nasopharyngeal narrowing (choanal atresia and pyriform aperture stenosis), thryoglossal duct cyst at base of tongue, infections and abscesses (including MAI and Cat Scratch Fever), vascular malformations, lymphatic malformations, malignancies such as rhabdomyosarcoma, head and neck epidermoid and dermoid cysts, bony lesions with airway compromise, and foreign bodies.
Findings/Discussion
A wide assortment of diagnoses can compromise the pediatric airway and include congential malformations of the maxillofacial region, aerodigestive tract and subglottic airway, acquired mucosal diseases such as infection and inflammation, masses and adenopathy. While the patient may be asymptomatic, the finding of airway compromise could develop into dire consequences for the patient. In the setting of a prenatal diagnosis, the diagnostic exams

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

we perform can alter the immediate postnatal care and necessitate multidisciplinary presence in the delivery room to provide necessary postnatal care to protect the airway. Congential anomalies can lead to airway narrowing or compromise. With fetal MRI better equipped to image this region of anatomy, a prenatal diagnosis can alter immediate postnatal care.
Summary/Conclusion
A wide assortment of pathologies in the pediatric head and neck can alter airway mechanics and have the potential for life-threatening consequences. In the prenatal and neonatal age group, careful sonographic evaluation and use of MRI for suspected fetal anomalies, immediate postnatal period can be optimized to ensure proper airway management and oxygenation of a newborn.

Flow-Diverting Stents in the Treatment of Intracranial Aneurysms: What the Neuroradiologist Needs to Know

Thurlow, P. C.·Ku, A.·Goldberg, M. F.
West Penn Allegheny Health System
Pittsburgh, PA.

Purpose
The management of large and giant wide-necked intracranial aneurysms (IAs) historically has represented a significant challenge for neurointerventional radiologists, with a high rate of rupture without intervention, high surgical mortality rates, and high recurrence rates following intervention. Flow-diverting stents, of which the Pipeline Embolization Device (PED) (EV3/Covidien) is currently the only FDA-approved device, offer a novel approach to the treatment of large and giant wide-necked IAs. The introduction of the PED into clinical practice requires radiologists to be familiar with the unique imaging characteristics of IAs treated with flow-diverting stents. The purpose of this exhibit is to discuss the role of flow diverting stents in the management of large and giant wide-necked IAs and present a case-based review of the computed tomography (CT), magnetic resonance (MR), and angiographic imaging characteristics of IAs treated with flow diverting stents.
Approach/Methods
This educational exhibit will begin with a review of the classification system for IAs and the natural history of giant, wide-necked, and fusiform IAs. A brief review of the conventional treatment options for IAs then will be undertaken. An overview of the applications, mechanism of action, clinical data, and imaging features of the PED then will be presented, followed by an interactive, case-based review of the CT, MR, and angiographic imaging characteristics of IAs treated with the PED over time.
Findings/Discussion
The participant will be presented with the classification system by size and configuration for IAs and learn the features of large and giant wide-necked IAs that make flow-diverting stents particularly effective in their treatment. The mechanism of action of the PED is through flow diversion and re-endothelialization. Because the PED obviates intrasaccular aneurysm packing and allows thrombus mass to be resorbed, mass effect symptoms, including cranial nerve neuropathies and headaches, also are alleviated. These effects are manifest on follow-up imaging as a gradual decrease in the size of the excluded aneurysm sac. Complete preintervention characterization of the aneurysm and an understanding of the imaging characteristics of the aneurysm over time following treatment with the PED are essential for appropriate treatment and followup.
Summary/Conclusion
Flow-diverting stents represent an important development in the management of large and giant wide-necked IAs. An understanding of the role of flow-diverting stents in IA management, as well as the imaging appearance of IAs treated with the flow-diverting stents, is essential for the practicing radiologist. This interactive educational exhibit provides an overview of large and giant wide-necked IAs and highlights the key features of the flow-diverting stent in the treatment of IAs through an interactive, case-based review.

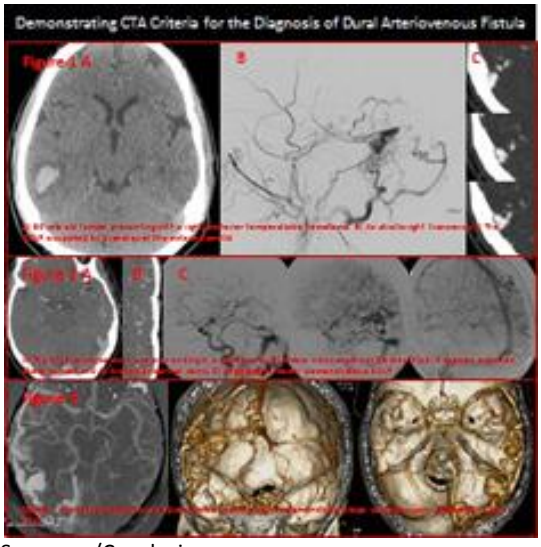
Demonstrating CTA Criteria for the Diagnosis of Dural Arteriovenous Fistula

Michalski, M. H.·Lawrence, D. A.·Minja, F.·Weisman, N.·Matouk, C.·Bulsara, K.·Johnson, M. H.
Yale New Haven Hosptial
New Haven, CT.

Purpose
Dural arteriovenous fistulas (dAVF), which consist of direct connections between dural arterial feeders and venous sinuses dural veins, are rare vascular abnormalities. While benign dAVFs rarely become symptomatic, aggressive lesions that involve the leptomeninges often present with significant neurologic symptoms or hemorrhage. On CTA studies performed in the emergent setting, these malformations can be mistaken for more common pial-based AVMs. However, diagnosis of dAVFs can be a critical distinction in the risk stratification and therapeutic management of these patients. Several imaging findings have been reported as being suggestive of dAVF; in this presentation, we demonstrate CTA imaging findings that have been useful tools in diagnosing dAVFs.
Approach/Methods
To explore methods for delineating dAVFs from pial AVMs, a review of angiographically confirmed cases of dAVF was conducted. Patients treated at a single academic institution over the past 10 years were assessed for the study. Patients who had inconclusive angiographic results, initially mixed AVF/AVM disease, or patients that did not have a CTA performed prior to their angiography were excluded. The resulting cases then were reviewed for CTA findings (and confirmatory correlates on other available modalities) unique to dAVFs to assist in their detection. These findings then were compared against several analogous studies of patients with pial AVMs in similar locations. In addition, a review of recent literature was performed to identify other reported dAVF imaging findings.
Findings/Discussion
After systematic review, several imaging findings were found which are suggestive dAVF. First, a intraparenchymal nidus of vessels, a characteristic finding of pial AVMs, could not be identified in dAVFs. Second, the presence of dilated cerebral veins without dilated feeding inflow vessels suggested a dural arterial source. Finally, venous sinus occlusions or blind ending venous pouches could reflect an underlying dAVF. Several examples of these findings in multiple locations within the cranial vault were obtained as examples for this presentation, along with matching negative examples with pial AVMs.



Summary/Conclusion
We demonstrate several CTA findings that can help in the diagnosis of dAVF, with multiple corresponding imaging examples of dAVFs juxtaposed with pial AVMs. These criteria can be helpful in the diagnosis, treatment and risk stratification of ambiguous AVMs that present in the emergent setting.

Basic Techniques of Neurointerventional Radiology: What the Neuroradiology Fellow Should Know

Shaikh, H.·Patel, N.·Bagley, L.·Pukenas, B.·Smith, M.·Hurst, R.
Hospital of the University of Pennsylvania
Philadelphia, PA.

Purpose
To illustrate and describe basic angiographic techniques that are important for neuroradiology fellows to learn.
Approach/Methods
Pictures and videos of neurointerventional physicians and fellows at our institution will be used in this exhibit to help illustrate basic neurointerventional techniques and their importance. Techniques of flush-line, catheter, wire, coil, stent, and embolic agent preparation will be discussed. Standard angiographic projections, rotational angiography, anatomical landmarks and hemostasis techniques will be reviewed. The Siemens' (Malvern, PA) Artis biplane angiography unit will be used for demonstration purposes. Various flow models also will be used to help illustrate basic vessel selection and contrast injection techniques.
Findings/Discussion
Integration to a neurointerventional service may be a daunting task, particularly for those fellows with limited prior angiographic experience. This exhibit hopes to develop a basic framework for understanding neurointerventional radiology and its role in the diagnosis and treatment of neurologic disorders. The exhibit will review pertinent elements of the preprocedural evaluation including patient symptomatology, physical exam, laboratory tests, prior imaging and anatomical variants. A systematic manner with careful attention to detail is required for each and every neurointerventional case. All catheters, lines, wires and other devices must be prepared and examined prior to usage in order to minimize risks (such as air emboli) to the patient. Optimizing radiographic projections, minimizing radiation dose, use of rotational angiography and 3D postprocessing techniques, and hemostasis techniques including use of closure devices will be covered. Techniques of obtaining arterial access as well as selective vascular catheterization, including road mapping techniques will be discussed. Postprocedural evaluation and assessment for possible complications are also imperative.
Summary/Conclusion
Appropriate preparation, careful attention to detail and mastery of basic techniques are essential in neurointerventional procedures to ensure patient safety. This exhibit attempts to detail basic neurointerventional techniques - in short, what every fellow should know.

KEYWORDS: Cerebral angiography, Educational, techniques

eEdE-127

Risk of Contrast-Induced Nephropathy in Patients Undergoing Treatment for Acute Stroke

Javadi, P.·Etesami, M.·Patel, T.·Blackham, K.
University Hospital Case Medical Center
Cleveland, OH.

Purpose
The purpose of this education exhibit is to discuss the rare incidence of and risk factors for contrast-induced nephropathy (CIN) after the use of iodinated contrast for endovascular treatment of acute ischemic stroke (AIS) as compared to the high risk of CIN in patients undergoing coronary angiography for myocardial infarction (MI).
Approach/Methods
A review of literature for the incidence and risk factors of CIN in patients receiving iodinated contrast for CT angiography or endovascular treatment in the setting of acute ischemic stroke was performed which was compared to the risk of CIN in patients receiving percutaneous intervention (PCI) for MI. Additionally, results from our institute for the incidence and risk factors for CIN in patients receiving endovascular treatment for AIS also have been included.
Findings/Discussion
There is an increased rate of 12-26% of CIN in patients with myocardial infarction who underwent PCI. Studies also have shown correlation of multiple risk factors including diabetes mellitus, previous history of chronic kidney disease, and amount of contrast used during the procedure with CIN. The majority of the studies showed higher incidence of CIN in patients with advanced renal disease, cardiogenic shock, volume depletion, poor ejection fraction and decreased cardiac output secondary to myocardial infarction. Association with poor clinical outcome and prolonged hospital stay have been well established. Previous studies have shown low incidence of CIN in acute stroke patients who underwent emergent multimodal CT scanning ranging from 2-3.7%. The only

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

published cohort of 99 patients undergoing endovascular therapy for acute ischemic stroke reported an incidence of 3% for acute contrast-induced nephropathy. Most of these cases of acute kidney injury had resolved after hydration. No patients in these study groups needed dialysis at discharge. No clear correlation between risk factors have been established, although study samples are small compared to the acute coronary syndrome (ACS) group. Postulated differences in incidence and complications of CIN in patients receiving iodinated contrast medium in ACS and acute ischemic stroke include cardiogenic shock in setting of MI, higher underlying comorbidities in patients with ACS, and pre-renal azotemia which is correctable with hydration in AIS. In our cohort of patients, the risk of developing CIN was relatively low among acute stroke patients who underwent emergent endovascular treatment (1.5%). Eighty-four percent (161) patients had a baseline creatinine less than 1.5 mg/dl. All but two patients with baseline creatinine of 1.5 mg/dL developed CIN. Female gender, history of diabetes and additional preceding CT angiogram in 44 patients were not associated with higher risk of developing CIN.
Summary/Conclusion
The risk of developing CIN is low among acute stroke patients who undergo emergent endovascular intervention. Laboratory investigation should not delay as much as known renal insufficiency should not preclude intra-arterial treatment of stroke. A prospective randomized clinical trial is warranted to evaluate long-term effects of use of contrast and interval development of chronic kidney disease.

KEYWORDS: Stroke, Complications, contrast-induced nephropathy

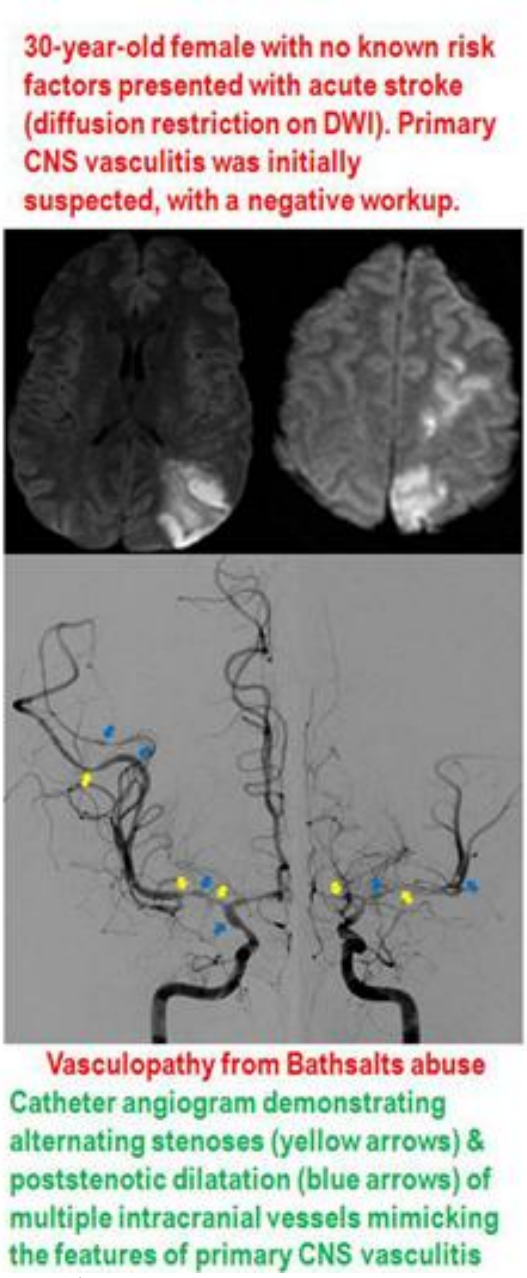
eEdE-128

"Recreational Vasculopathy or Vasculitis": Not So Fun for Your Brain

Supsupin, E. P.[1]·Lee, P.[2]·Dahlin, B.[2]
[1]University of Texas Medical School at Houston, Houston, TX, [2]University of California Davis, Davis, CA.

Purpose
This is a pictorial essay of cerebrovascular manifestations resulting from abuse of recreational drugs. We recently observed the emergence of such conditions in our practice.
Approach/Methods
The vasculopathic/vasculitic changes associated with recreational substances of abuse gaining in popularity such as Bathsalts (street names: "Ivory Wave", "Purple Wave", "Vanilla Sky", and "Bliss") and Ecstasy (MDMA: 3,4-methylenedioxymethamphetamine) and the more familiar drugs such as marijuana, cocaine, and similar agents are the main focus of this discussion. Emphasis on the neuroimaging/neuroangiographic presentations of these cases, in correlation with their clinical manifestations on the basis of pharmacologic and toxicologic mechanisms will highlight this presentation.
Findings/Discussion
Newer recreational substances of abuse are designed to elude detection by routine UDS (urinary drug screen). The lack of awareness by the general medical community of their existence despite their rising popularity, and the similarity of angiographic features between primary CNS vasculitis and drug-induced vasculopathy/vasculitis, have contributed significantly to delayed diagnosis and treatment. Typically in our experience, an adolescent or young adult without clear or known risk factors presenting with acute hemorrhage or stroke raises the "red flag" that heralds the correct diagnosis. Awareness of this rising problem and its clinical and radiologic manifestations is important for early diagnosis and appropriate management, obviating the need for costly and sometimes invasive diagnostic procedures (i.e., brain biopsy). The distinction between secondary vasculopathy/vasculitis induced by recreational drugs and illicit substances versus primary central nervous system (CNS) vasculitides is important. Drug-induced vasculopathy is managed conservatively by identifying and removing the offending agent. While calcium channel blockers and angioplasty have been utilized to treat selected patients exhibiting rapid clinical deterioration, no established therapy exists. In contrast, primary CNS vasculitis is treated with immunosuppressive therapy.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.



Summary/Conclusion
The cerebrovascular insults resulting from abuse of recreational substances are presented. The diagnosis of secondary vasculopathy/vasculitis must be suspected in a young patient without risk factors presenting with acute hemorrhage or stroke. Whereas angiography cannot reliably distinguish primary from secondary vasculitis/vasculopathy and because some recreational substances are undetectable on routine UDS, cognizance and prompt recognition are crucial in efficiently arriving at the correct diagnosis and timely institution of appropriate therapy.

Brain Squids: Expanding the Imaging and Clinical Spectrum of Developmental Venous Anomalies in Children

Linscott, L.·Leach, J. L.·Jones, B. V.·Abruzzo, T.
Cincinnati Children's Hospital Medical Center
Cincinnati, OH.

Purpose
Developmental venous anomalies (DVAs) commonly are identified on imaging examinations and typically are treated as incidental findings with no significant clinical manifestations. Increasing imaging identification of DVAs has led to recognition of their association with a variety of conditions. This presentation will review the imaging spectrum of these common vascular anomalies, give multiple case examples using multimodality imaging, and review the suspected embryologic origin and pathophysiologic mechanisms of DVAs in the pediatric population.
Approach/Methods
Developmental venous anomalies were identified by searching the radiology information system using a database search engine for the terms "venous angioma" , "developmental venous anomaly", "angioma", and "venous" at a large tertiary care academic childrens hospital. Case material was obtained from identified cases for educational presentation. Imaging from MRI, SWI, MRV, CT, CTV, and angiography will be presented and correlative clinical information will be discussed. Information regarding the prevalence, distribution, and morphology of DVAs will be presented.
Findings/Discussion

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

The spectrum of imaging findings associated with DVAs is more extensive than traditionally appreciated. Understanding the typical "squid-like" appearance of DVAs is important for accurate identification, and avoiding misdiagnosis. Most DVAs represent incidental variations in venous anatomy; however, they can be associated with other lesions and conditions. Restriction of flow through the collecting vein by thrombosis or stenosis may give rise to parenchymal injury. Identification of DVAs in planned surgical trajectories is of critical importance, as disruption may lead to significant parenchymal sequelae. Multiple case examples will be presented with emphasis on typical and atypical imaging appearances, associated parenchymal manifestations, as well as known associations with cavernous malformations, migrational anomalies, AVMs, and fistulas. The relationship of DVAs to head and neck venous malformations and important neurocutaneous syndromes will be presented.
Summary/Conclusion
Although most DVAs are incidental findings, a wide range of other brain lesions and conditions may be related to these vascular anomalies. Although imaging manifestations of DVAs are well known, a wide spectrum of sizes and drainage patterns are encountered, that should be understood when interpreting imaging exams.

KEYWORDS: , developmental venous anomaly

eEdE-130

Imaging Spectrum of Venous-Related Cerebral Injury in Children

Linscott, L.·Leach, J. L.·Abruzzo, T.
Cincinnati Children's Hospital Medical Center
Cincinnati, OH.

Purpose
To review the developmental anatomy, pathophysiology, and imaging patterns of venous-related cerebral injury in children. Emphasis will be placed on unifying concepts to better understand the effects of venous hypertension/insufficiency in the developing child, providing the imaging professional with a conceptual framework to better understand and confidently identify imaging patterns of venous-related cerebral injury.
Approach/Methods
Case material will be identified by clinical chart review and detailed imaging review using an automated radiology/pathology database application at a large tertiary care pediatric hospital. Modalities presented will include MRI (including perfusion, spectroscopy, SWI, and DTI), CT, CTA, MRA, MRV, MR perfusion, and angiography.
Findings/Discussion
Venous-related brain injury is a common form of cerebrovascular injury in children. The developmental and acquired causes of venous-related cerebral injury comprise a diverse, heterogeneous group of diagnoses. Examples include: germinal matrix hemorrhage in preterm neonates, periventricular hemorrhagic infarction, cerebral angiomatosis (Sturge-Weber syndrome), acute and chronic cerebral venous thrombosis, and congenital and acquired venous and arteriovenous malformations and fistulas. Despite the heterogeneity of these diagnoses, injury to the brain occurs along common pathways of venous hypertension/insufficiency, ischemia, and hemorrhage.
Summary/Conclusion
Venous-related injury to the developing brain is found in a heterogeneous group of cerebrovascular disorders. An improved understanding of common pathophysiologic pathways provides the imaging professional with a conceptual framework to correctly identify imaging patterns of venous-related brain injury, direct appropriate therapy, and avoid diagnostic pitfalls.

Pediatric Stroke: An Interactive Tutorial

Djoukhadar, I. A.·Macmullen-Price, J.·Warren, D. J.
Leeds Radiology Academy
Leeds, UNITED KINGDOM.

Purpose
We aim to review the imaging strategies and findings encountered in pediatric stroke. Ultimately the objective of this educational electronic exhibit is to enhance residents' confidence in making accurate and early diagnosis during oncall commitments.
Approach/Methods
The exhibit format will include case-based review of various pediatric strokes.
Findings/Discussion
Stroke in the pediatric population is relatively infrequent and the diagnosis often is delayed and occasionally missed. Early stroke diagnosis and treatment is essential in improving long-term functional outcome and preventing recurrence. We present a comprehensive review with a selected mix of cases, the imaging features of different stroke subtypes including arterial thrombosis, vasculitis, sinovenous thrombosis and hemorrhagic causes. Emphasis will be placed on the imaging features that allow early and accurate diagnosis. Some imaging mimics and potential pitfalls also will be highlighted. An interactive self-assessment exam will be presented at the end of the exhibit.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Summary/Conclusion

In demonstrating the different stroke imaging features and in the common diagnostic pitfalls, this exhibit will enhance the residents' understanding and confidence in making accurate diagnosis. After reviewing this electronic exhibit, the learner will be able to test their understanding through an interactive self-assessment.

Review of Normal and Abnormal Intracranial Processes Leading to Various T2 and FLAIR White Matter Signal Alterations in the Pediatric Brain

Meesa, I.·Ibrahim, M.·Mukherji, S.
University of Michigan
Ann Arbor, MI.

Purpose

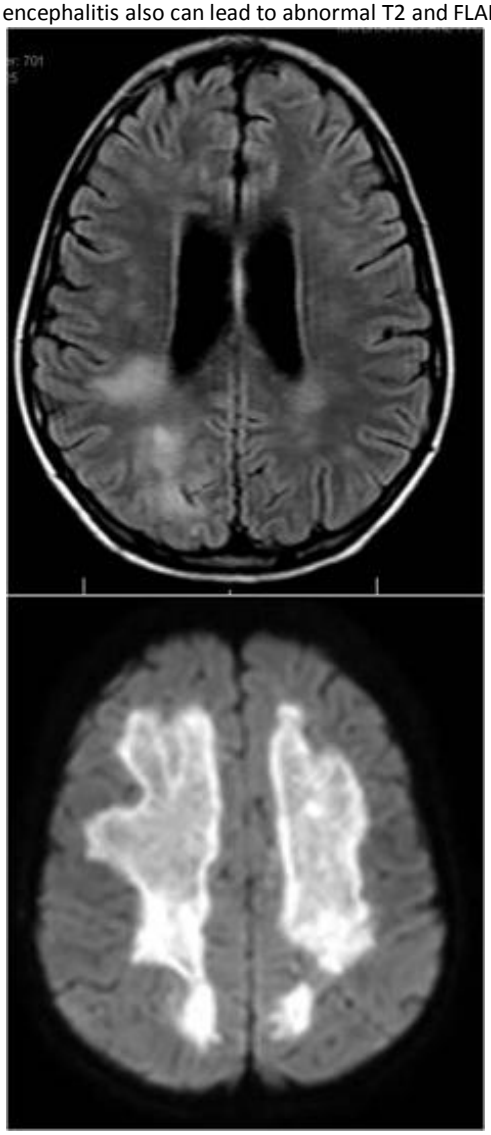
The purpose of this exhibit is to review the various physiologic and nonphysiologic processes that lead to T2 and FLAIR MRI signal alterations in the pediatric brain and how the radiologist can use clinical information (age, clinical history, and labs) along with various imaging sequences such as diffusion and imaging such as proton MR spectroscopy to distinguish one process from the other.

Approach/Methods

We will perform a retrospective review of the MRIs in infants and young children performed at our institution over the last 10 years with the following findings: normal myelination, abnormal myelination, inflammatory (ADEM), and infectious (encephalitis) conditions and determine how we used age, clinical data, and imaging to come to the right diagnosis.

Findings/Discussion

Both normal physiologic myelination and abnormal pathophysiology can lead to signal alterations. For example, in infants and young children, the deep cerebral white matter shows a triphasic sequence of white matter signal change. Additionally, because the temporal lobes are nearly the last to undergo myelination, the more peripheral white matter can remain hyperintense on FLAIR images beyond 24 months of age. Attention to age is important. Pathophysiologic mechanisms affecting myelin can lead to white matter abnormalities. Three main pathophysiologic mechanisms that would affect myelination are: hypomyelination, demyelination, and rarefaction. Because these processes often result in similar MR white matter findings, we will illustrate how proton MR spectroscopy can be used to help differentiate one process from the other. Additionally, inflammatory processes such as ADEM and infectious processes such as encephalitis also can lead to abnormal T2 and FLAIR signal.



Summary/Conclusion

In conclusion, by using all available data [age, underlying medical conditions, clinical history (physical exam and labs)] and additional imaging sequences such as FLAIR, diffusion, and proton MR spectroscopy the radiologist will be able to arrive at an appropriate diagnosis.

KEYWORDS: Demyelination, Acute disseminated encephalomyelitis, encephalopathy

eEdE-133

Congenital Brain and Spine Anomalies: Detection with Fetal MR Imaging and Postnatal Correlation

Supakul, N.·Kralik, S. F.·Ho, C. Y.
Indiana University School of Medicine
Indianapolis, IN.

Purpose
To demonstrate the spectrum of congenital malformations of the central nervous system (CNS) detected from fetal magnetic resonance imaging (MRI) and to correlate with postnatal imaging.
Approach/Methods
From our computerized radiology system (2008-2012), patients who had an abnormal obstetrics ultrasound (US) with MRI follow-up imaging were identified (n = 160). The fetal MRI study was reviewed for recognizable CNS pathology and correlated with postnatal imaging studies (n = 65) including US, computed tomography (CT) or MRI.
Findings/Discussion
We will demonstrate several cases of congenital pathologies of the brain and spine detected from fetal MRI with postnatal imaging correlation. These include neural tube closure defects [Chiari malformation (n = 11), encephalocele (n = 4), and myelomeningocele without Chiari (n = 5)], disorders of diverticulation [holoprosencephaly (n = 2) and corpus callosum anomalies (n = 4)], neuronal migration and sulcation abnormalities [schizencephaly (n = 2)], posterior fossa malformations [Dandy-Walker malformation (n=6)], and congenital tumors and vascular lesions [epignathus (n = 1), venolymphatic malformation (n = 2), sinus thrombosis (n=2)]. The imaging techniques, commonly missed diagnoses and key findings will be discussed.
Summary/Conclusion
Fetal MRI is a useful imaging modality, providing valuable clinical information not seen on US. This information will help parents make decisions during the pregnancy, and possible advanced treatment during the pre and postnatal period. Familiarity with fetal MRI imaging and diagnosable CNS pathology can improve accuracy and patient care.

eEdE-134

Congenital Dermal Sinus Imaging: A Ten-Year Institutional Review of Pediatric Spinal MR Imaging

Cagley, J. R.·Figi, A. R.·Selden, N. R.·Pollock, J. M.
Oregon Health and Science University
Portland, OR.

Purpose
Dermal sinus tracts have a variety of imaging appearances ranging from the clinically and radiographically obvious to the occult. In this imaging-based review, we will present the common imaging features and diagnostic pearls regarding MRI evaluation of dermal sinus tracts.
Approach/Methods
A 10-year retrospective search of the radiologic information system was utilized to identify reports with mention of a dermal sinus tract on all MRI spine reports in a pediatric population at our institution. The results of this search were reviewed by the radiology staff. Dermal sinus tracts were classified on type, location, and associated imaging features.
Findings/Discussion
Seven hundred exams were searched yielding 614 instances of keywords associated with dermal sinus tracts. The 700 cases were reviewed by the authors yielding 25 positive cases. Twenty-two cases were observed in the lumbar spine, two cases were in the thoracic spine, and one case was in the sacrum. Common associations included dermoid or lipomas, diastematomyelia, and cord tethering. Most dermal sinus tracts were identified in the subcutaneous tissues on T1 and T2 sagittal imaging. The dura in most cases demonstrated a small notch at the point of communication between the dermal sinus tract and the thecal sac. The most pathognomonic cases will be presented here highlighting the imaging features and diagnostic pearls.
Summary/Conclusion
Dermal sinus tracts are an important entity in the pediatric population as delay in diagnosis may result in increased morbidity. In this educational exhibit, we have reviewed the common imaging features and diagnostic pearls identified from a retrospective search. Awareness of these imaging features and pearls may allow the practicing radiologist to more confidently diagnose these entities and associated pathologic features.

eEdE-135

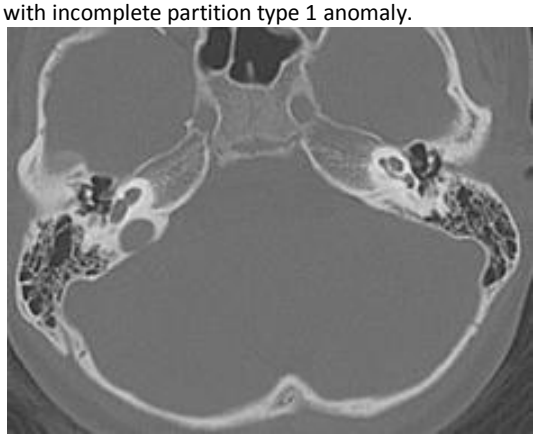
Imaging Review of Congenital Inner Ear Anomalies

Singh, A. K.[1]·Bathla, G.[2]·Sato, Y.[2]·Tiwari, R.[3]
[1]University of Texas Health Science Center, San Antonio, TX, [2]University of Iowa Hospitals and Clinics, Iowa City, IA, [3]Bhopal Medical Center, Bhopal, INDIA.

Purpose
The purpose of this exhibit is to review the imaging findings of congenital inner ear anomalies in an interactive format.
Approach/Methods
We retrospectively reviewed the cases of congenital inner ear anomalies and their representative images were used for this exhibit.
Findings/Discussion
The etiology of profound sensorineural hearing loss in children is multifactorial with congenital inner ear anomalies being an important category which can be

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

diagnosed by imaging. The cochleovestibular anomalies are classified in order of decreasing severity: labyrinthine aplasia, cochlear aplasia, common cavity deformities, cystic cochleovestibular malformations (IP-1), cochleovestibular hypoplasia, and incomplete partition type 2 (IP-2). Other inner abnormalities are associated with abnormal development of semicircular canal, cochlear nerve, vestibular aqueduct and internal auditory canal. The imaging appearance of these entities is reviewed in an interactive format with subsequent discussion. The figure shows cystic appearance of right cochlea and vestibule with partition in between consistent with incomplete partition type 1 anomaly.



Summary/Conclusion
Congenital inner anomalies are an important cause of sensorineural hearing loss. Recognizing these anomalies on imaging is helpful in the management. Our goal is to review the imaging appearance of these anomalies in an interactive format.

KEYWORDS: Cochleovestibular malformations, Sensorineural hearing loss

Cerebral Palsy

Izbudak, I.[1]·Poretti, A.[1]·Huisman, T. A. G.[1]·Lequin, M. H.[2]
[1]Johns Hopkins University, Baltimore, MD, [2]Sophia Children's Hospital, Erasmus, NETHERLANDS.

Purpose
Cerebral palsy (CP) is the most common physical disability in childhood and about 2-3 of every 1000 live born children in the Western world are affected. Although it is a clinical diagnosis neuroimaging plays an important role to identify the etiology and pathogenesis, to differentiate from mimickers, to predict the neuromotor and cognitive outcome, and to evaluate response to neuroprotective treatments. Our goal in this review is 1. to demonstrate conventional MRI and advanced neuroimaging findings in cerebral palsy; 2. to present the role of early neuroimaging to predict cerebral palsy.
Approach/Methods
We will present a wide spectrum of conventional brain MRI findings in children with cerebral palsy; emphasizing the relation between MRI pattern of lesions and different clinical phenotypes. We also will present brain MRI findings of CP mimickers. The advanced MR imaging techniques in recent decade [e.g., diffusion-weighted imaging (DWI), diffusion tensor imaging (DTI), magnetic resonance spectroscopy (MRS), susceptibility-weighted imaging (SWI), volumetric MRI, functional MRI (fMRI), resting state fMRI] have significantly improved our understanding of CP at microstructural level. We will present examples of these advanced neuroimaging results in children with cerebral palsy. Lastly we will emphasize the value of neuroimaging (fetal ultrasound and MRI) during fetal, neonatal and infantile period in predicting neuromotor outcome when there is suspicion of brain injury/malformation in early life.
Findings/Conclusion
Neuroimaging is not necessarily required for diagnosis of cerebral palsy because the disorder is based on clinical findings. The principal contribution of neuroimaging is to the understanding of etiology and pathogenesis, that may have implications for genetic counseling.
Summary/Conclusion
Earlier diagnosis of CP may be possible with implementation of early neuroimaging biomarkers that might allow early treatment interventions in the near future.

KEYWORDS: Cerebral palsy, Imaging biomarker, structural and functional neuroimaging

eEdE-137

Craniofacial Syndromes and Congenital Midface Anomalies: What the Radiologist and Clinician Need to Know Regarding Midfacial Anomalies and Other Associated Conditions

Gul, M.[1]·Chaudhry, A. A.[2]·Dunkin, J.[2]
[1]Winthrop University Hospital, Mineola, NY, [2]Stony Brook University Medical Center, Stony Brook, NY.

Purpose
1. Review of embryology, clinical findings, imaging features with histopathology correlation of congenital midface anomalies. 2. Enumerate the more common types of craniofacial syndromes with emphasis on their characteristic radiologic features and differential diagnostic considerations.
Approach/Methods
1. Review midfacial embryogenesis, normal development of anatomical structures and review factors that lead to abnormal development. 2. Identify imaging findings and review of treatments and prognosis of various nasal cavity/nasofrontal anamolies, craniofacial syndromes and congenital midline masses. 3. Case-based discussion of mimics resulting from infection, inflammation, injury and/or malignancy that may mask and/or mimic congenital anomalies will be discussed.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Findings/Discussion
1. Detailed pictorial discussion (cartoon and/or radiographic demonstration) of craniofacial embryogenesis highlighting key embryologic and anatomical locations with emphasis of factors that lead to abnormal development. 2. Identify and describe radiographic, ultrasound, CT and/or MR imaging findings followed by discussion of treatments and prognosis of the following entities: a. Nasal cavity/nasofrontal anamolies: pyriform aperture stenosis, choanal atresia, nasolacrimal duct anomalies (nasolacrimal duct stenosis). b. Craniofacial syndromes: Crouzon syndrome, Treacher Collins syndrome, Pierre Robin syndrome, Apert syndrome, Cornelia de Lange syndrome, Hay Wells syndrome, Axenfeld syndrome. c. Congenital midline masses: Dermoid, epidermoid, nasal glioma, encephaloceles, chordoma. 3. Clinical findings, key imaging findings, histopathology, treatment and prognoses of the following will be discussed: a. Lymphoma, b. Metastases, c. Abscess, d. Tuberculosis, e. Hemangiopericytoma, f. Malignant fibrous histiocytoma, g. Fibrous dysplasia, h. Chloroma.
Summary/Conclusion
1. Congenital mid-facial anomalies are a common entity that requires early recognition and intervention. In order to provide an early diagnosis and appropriate therapy radiologists and clinicians must have a good understanding of mid-facial embryogenesis and normal development of anatomical structures. 2. By the conclusion of this presentation, the radiologist should have a better understanding of various clinical presentations of congenital mid-facial anomalies and relevant imaging findings. 3. Although numerous craniofacial syndromes exist, differential diagnosis can be narrowed utilizing age, clinical features, and imaging characteristics (e.g., lesion location, enhancement pattern, necrosis, etc).

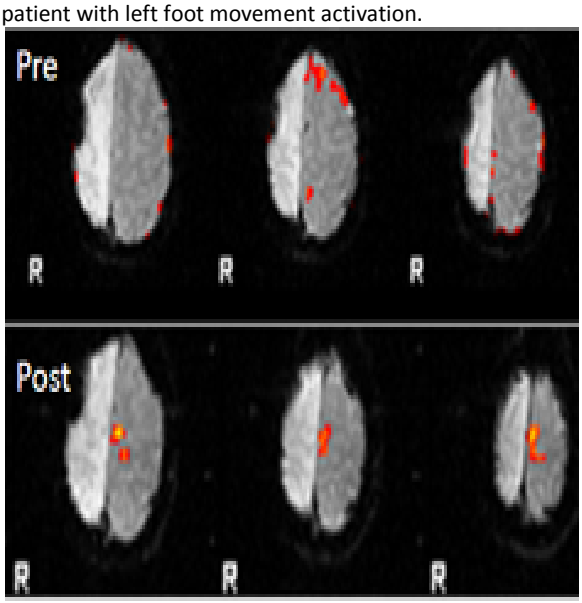
eEdE-138

Functional Neuroimaging of Patients with Post Hemispherotomy Pre- and Post-Intensive Gait Therapy

Salamon, N.·Debode, S.·Bookheimer, S.
University of California Los Angeles
Los Angeles, CA.

Purpose
Many patients with intractable epilepsy underwent hemispherotomy for seizure control, plasticity and reorganization of the motor control may develop after surgery. We studied motor and gait functions pre- and post-body weight support treadmill (BWST) training, and correlate changes from training using functional MRI (fMRI) cortical activation from voluntary knee movements. Our goals are to exploit functional plasticity in the developing human brain by determining if age at injury/surgery, related to specific pathologies, predicts baseline motor/gait functions and response to BWST training.
Approach/Methods
Diffusion tensor imaging (DTI): An axial 2D EPI based diffusion-weighted sequence (Siemens Allegra 3.0T TE/TR 129/6000ms, FOV 240 x 240 mm, matrix 128 x 128 interpolated to 256 x 256, slice thickness 2 mm, number of slices 70) will be acquired with diffusion gradients along 32 noncollinear directions at two b values of 600 sec/mm2 and 1200 sec/mm2. fMRI: functional MRI analysis will be obtained using motor sensory testing using knee movement. Control and 5 posthemispherectomy patients had received BWST training and pre and postfMRI was performed. Data analyses were made using a statistical program (Stat View SAS Institute, Cary,NC). Differences between control and hemispherectomy patients were compared using t test and repeated-measured analysis of variance. Comparisons using nominal variables were performed using chi-square tests. Results were considered at a minimal level of significance of P<.05.
Findings/Discussion
For hemispherectomy patients, the increase in activation of the voxel was obtained in ipsilateral paretic and contralateral nonparetic movements (p<.02) after BWST. For control subjects, there was decrease in activity in the voxels after BWST. Attached image demonstrates pre and postBWST fMRI result of the right hemispherectomy patient with left foot movement activation.



Summary/Conclusion
Locomotor therapy such as BWST can improve motor connectivity in hemispherectomy patients. Further study is needed to optimize motor functions of the residual corticospinal pathway and long term follow-up assessment with fMRI will be helpful in future research.

KEYWORDS: Hemimegalencephaly, Motor development, fMRI

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eEdE-139

Acute Ischemic Infarct in Neonates: The 3 Tesla MR Imaging Experience

Thompson, A. F.·Wang, Y. Y.
University of Wisconsin
Madison, WI.

Purpose
The purpose of this study is to share our initial findings of 3T MR imaging (MRI) studies performed on neonates presenting acutely with brain ischemia to a university-affiliated community hospital.
Approach/Methods
A brief outline of the known benefits and drawbacks of 3T MRI in neonates will be presented, as will the specific aspects of our 3T MRI neonatal brain protocol. Additional background information on the typical MRI findings of both acute ischemic infarct and hypoxic-ischemic injury in neonates also will be described briefly. We then have a selection of 26 3T MRI studies performed an average of two days from initial presentation on neonates with acute onset symptoms of infarct, most often including seizure, apnea, or focal neurologic deficit. The neonates were an average of six days old at the time of the first diagnostic 3T MRI study, and a variety of pathologies are exemplified on imaging, including acute unifocal and multifocal ischemic arterial infarcts, acute venous infarct, old prenatal infarct, acute hypoxic-ischemic insult, and germinal matrix hemorrhage.
Findings/Discussion
It is well known that the increased field strength of a 3T MR scanner causes a two-fold increase in the signal-to-noise ratio (SNR) when applied clinically. At our institution, it also decreases the scanning time for a given study by one third when compared to 1.5T MRI. While most patient populations ultimately can benefit from these key basic features of 3T MRI, the advantage to neonates is particularly significant. Our 26 cases demonstrate these benefits. Specifically, the higher resolution on standard MR sequences allows for better definition of both the neonatal neuroanatomy and any associated pathology. Higher resolution of apparent diffusion coefficient (ADC) maps may be more sensitive to penumbra and therefore to key prognostic findings such as pre-Wallerian degeneration in settings of stroke. Higher resolution susceptibility-weighted imaging (SWI) may be more sensitive to hemorrage. Ultimately, the increased resolution of the study as a whole may allow earlier disease detection. Furthermore, faster scan times reduce the need for sedation and the likelihood of motion artefact when compared to standard 1.5T MR imaging. At our institution we do not require sedation for a full 3T MRI study that includes pre and postcontrast sequences and even MR spectroscopy in some cases. It therefore bypasses all risk factors associated with anesthesia, unlike with our previous 1.5T MRI studies.
Summary/Conclusion
The increased magnetic field strength of a 3T MRI enables acquisition of higher resolution sequences in one-third of the time needed at 1.5T. In neonates, this has considerable potential, as exemplified in our cases, for disease detection as early as, or possibly earlier than, with 1.5T. Furthermore, even if disease is not detected earlier, the shortened scan times of 3T MRI allow for complete bypass of sedation, making it a safer, lower risk study than that performed with sedation at 1.5T. Because of this, quick brain studies are no longer needed at our institution, as 3T MRI scans can be performed instead.

KEYWORDS: 3T, Neonatal MR imaging, brain ischemia

eEdE-140

3T MR Imaging of Pre-Wallerian Degeneration in Neonates Presenting with Acute Infarct

Thompson, A. F.·Wang, Y. Y.
University of Wisconsin
Madison, WI.

Purpose
Pre-Wallerian degeneration (PWD) is a critical finding on brain MR imaging (MRI) in patients presenting with infarct, as it has significant, life-long prognostic implications. This case-based study highlights the benefits of using 3T MRI to detect PWD in neonates presenting with acute ischemic infarct.
Approach/Methods
Pre-Wallerian degeneration first will be defined, its typical imaging features in neonates described, and its impact on prognostication discussed. From the initiation of neonatal 3T MRI at the community hospital affiliated with our institution in February until December 2012, approximately 46 patients under the age of 28 days were scanned, 26 of whom had MRI findings consistent with acute ischemic brain injury, and 15 cases which showed extensive ischemia. The 26 patients were an average age of 6 days at the time of the MRI scan, and MRI was performed an average of 2 days after presentation. Of these 26 patients, 12 showed pre-Wallerian degeneration on MRI. Each of these 12 cases also were included in the 15 patients who presented with extensive ischemic infarct. These cases will be presented, including the commonalities and differences in their clinical presentations, their varied initial clinical courses, and their key imaging findings.
Findings/Discussion
3T MRI has the benefit of increased signal-to-noise ratio (SNR), which is particularly relevant to the imaging of neonatal neuroanatomy and neuropathology. The resulting high resolution of the 3T field is manifested on all MR sequences, including those most important to the diagnosis of infarct and PWD, diffusion-weighted imaging (DWI) and apparent diffusion coefficient (ADC) maps. 3T MRI has the added benefit of shortened scan times, so much so that our institution requires no sedation of

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

neonates undergoing 3T MRI exams. Pre-Wallerian degeneration carries a poor neurodevelopmental prognosis, and as such its detection may alter clinical treatment, such as change in the type of rehabilitation used or earlier implementation of experimental therapies. Twenty-six neonates presented with ischemic infarct, 15 of whom had extensive ischemic infarct, and of these, 12 patients were found to have PWD. This suggests a high detection rate of PWD by 3T MRI in patients with extensive ischemic infarct. Current literature suggests a sensitivity of 83% for discovery of PWD in neonates presenting with acute arterial infarct scanned with a 1.5T MRI (Kirton et al.). The 3T MRI has the added benefit, however, of not requiring sedation, therefore making it a lower risk procedure than 1.5T MRI.

Summary/Conclusion

Discovering PWD on MR imaging is a key factor in determining the prognosis of infants presenting with ischemic infarct. Though 1.5T MRI has been shown to be effective in detecting PWD, its longer acquisition time predisposes the study to motion artifact, necessitating neonatal sedation for the study. Our experience shows that MR imaging at 3T is similarly effective in detecting the critical result of neonatal PWD in patients presenting with extensive ischemic infarct, while not using any sedation. Therefore, in an effort to minimize the risk to neonates undergoing MR imaging, we favor the use of 3T MRI when available.

eEdE-141

Leukemia in the Central Nervous System: Imaging of the Disease and the Collateral Damage

Bathla, G.·Policeni, B.·Sato, Y.
University of Iowa Hospitals and Clinics
Iowa City, IA.

Purpose

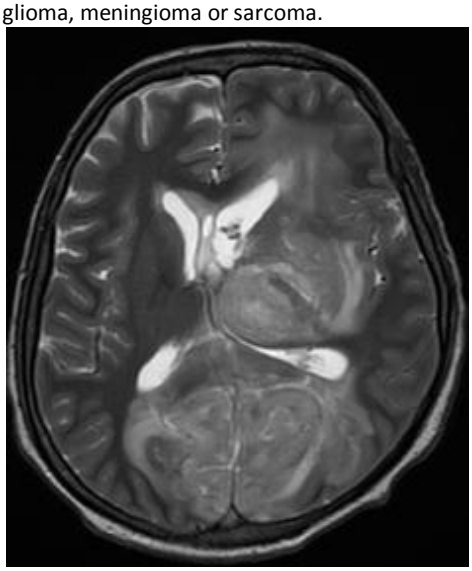
1) To briefly discuss the various early and late complications that may be encountered in patients with acute leukemia, both at presentation and as a result of therapy. 2) To review the imaging spectrum and classic neuroimaging appearances that may be seen, either as a consequence of the primary disease or secondary to the effects of treatment.

Approach/Methods

1) The exhibit aims to review the pertinent imaging findings in the central nervous system (CNS) through a brief yet concise review of the existing literature. 2) This is accompanied by a comprehensive review of the imaging manifestations of both the disease as well as the treatment complications that may be encountered.

Findings/Discussion

Leukemia is the most common malignancy in the pediatric population. Prior to the introduction of chemotherapy, CNS complications of leukemia rarely were encountered since the disease had an aggressive course and was almost uniformly fatal. Advance in medical care, including introduction of aggressive chemotherapy regimens have reduced significantly the associated mortality. However, the incidence of CNS complications has increased, both as a consequence of the longer survival and secondary to the aggressive chemoradiation. Neuroimaging findings in these patients can be subdivided as those secondary to the leukemia itself and those that occur as a result of therapy. The former include parenchymal hemorrhage, chloromas, meningeal and orbital disease. The latter can be further classified as those secondary to chemotherapy, radiotherapy and those resulting from immunosuppression. These include cerebrovascular complications, white matter disease, posterior reversible encephalopathy, microvascular angiopathy, parenchymal atrophy, vascular malformations and atypical infections. Finally, these patients also have a higher incidence of developing a second malignancy which may include a glioma, meningioma or sarcoma.



Summary/Conclusion

Advances in leukemia treatment have been accompanied by a higher incidence of CNS complications. Imaging not only plays a key role in diagnosis, but often affects management in select cases. Through this exhibit, we present a concise, but comprehensive, review of different CNS pathologies which may be encountered in leukemic patients.

KEYWORDS: Leukemia, Radiation effects, chemotherapy

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Brain and Leukemia: The Common, the Rare and the Unexpected

Alsharief, A. N. A.·Batawi, A. A. A.·Adas, R.·Almehdar, A.
King Abdul-Aziz Medical City
Jeddah, SAUDI ARABIA.

Purpose
To present the imaging features of the broad spectrum of intracranial pathologies in leukemic patients as identified on both computed tomography (CT) and MR imaging (MRI).
Approach/Methods
We retrospectively reviewed the brain imaging studies of pediatric and adult leukemic patients in our institution performed from January 2012 to present to document and review the different intracranial pathologies in these patients.
Findings/Discussion
Leukemia is the most common childhood malignancy, accounting for one third of all new malignancies. Although these patients initially can present with neurologic symptoms, intracranial involvement can be discovered before clinical symptoms become evident. Generally, Intracranial findings in leukemia can be classified into two major categories; pathologies related to the primary disease, such as chloroma and leukemic cell infiltration; and findings related to complications of the disease and/or medication, including hemorrhage, thrombosis, secondary infections and drug toxicity. Some of these complications appear early in the course of the disease as posterior reversible encephalopathy syndrome and methotrexate-induced neurotoxicity, while other complications can appear later. It is crucial to inquire about the nature and onset of symptoms, the type and duration of chemotherapy and the immune status. Good history and thorough knowledge of this wide range of pathologies is the radiologist's key to reaching the proper imaging diagnosis and therefore aid hematologists and oncologists in optimizing their patient's care.
Summary/Conclusion
Early identification and correct diagnosis of intracranial abnormalities associated with leukemia are crucial for daily practice of radiologists, particularly those working in hematology and oncology centers. This is because the general overall long-term disease-free survival rate of leukemia is around 80% and many related intracranial complications are treatable.

KEYWORDS: Leukemia, Brain, intracranial, CT, MR imaging

MR Imaging of Pediatric Pineal Gland Lesions

Gross Kelly, T. C.[1]·Cakmakci Midia, E.[2]·Guleria, S.[3]·Firat, S.[2]·Jogal, S.[2]·Maheshwari, M.[2]·Segall, H. D.[2]
[1]Children's Hospital of Wisconsin, Milwaukee, WI, [2]Children's Hospital of Wisconsin/Medical College of Wisconsin, Milwaukee, WI, [3]University of Alabama, Tuscaloosa, AL.

Purpose
The purpose of this educational exhibit is to provide a systematic diagnostic approach for the evaluation of pediatric pineal gland lesions. There are a wide range of lesions that may be seen in the pineal region. In order to facilitate diagnostic evaluation of pineal region masses, they can be grouped into 4 categories: (1) germ cell tumors (2) pineal parenchymal neoplasms, (3) neoplasms arising from adjacent tissues and (4) nonneoplastic masses.
Approach/Methods
In this exhibit we will review: (1) embryology, histology and anatomy of the developing pediatric pineal gland as well as (2) MR imaging (MRI) features of neoplastic and nonneoplastic lesions within and around the pineal gland.
Findings/Discussion
The MR appearance of pediatric pineal gland lesions such as pineal gland cysts, germ cell tumors, pineocytoma, teratoma, anlage tumors, papillary tumors and others will be reviewed. MR imaging features that can help differentiate neoplastic from non-neoplastic tumors will be highlighted.

Summary/Conclusion
Our goal is to provide a succinct review of the MRI appearance of neoplastic and non-neoplastic pineal gland lesions in order to facilitate detection and diagnosis of pineal gland abnormalities in the pediatric patient. We will achieve this goal by reviewing normal MR anatomy of the pineal gland followed by examples of lesions that can arise within or around the pineal gland.

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eEdE-144

Atypical Teratoid Rhabdoid Tumors: Review of Imaging Features

Mazumder, A. A.[1,2]·Adams, A.[1]·Paine, S. M. L.[3,1]·Jacques, T. S.[3,1]·Mankad, K.[1]
[1]Great Ormond Street Hospital for Children NHS Foundation Trust, London, UNITED KINGDOM, [2]The National Hospital for Neurology and Neurosurgery, London, UNITED KINGDOM, [3]Birth Defects Research Centre, UCL Institute of Child Health, London, UNITED KINGDOM, [4]Great Ormond Street Hospital for Children NHS Foundation Trust, London, UNITED KINGDOM.

Purpose
Pediatric atypical teratoid rhabdoid tumor (ATRT) of the brain is an aggressive and rare tumor. There are various imaging findings that assist with differentiating these from other tumors, for example medulloblastomas and choroid plexus papillomas. The pathologic characteristics of the tumor closely resemble those of the renal rhabdoid tumor of infancy. Cytomorphologic appearances of this tumor include hypercellularity with tissue fragments; large, round, and pleomorphic “plasmacytoid” cells; and “rhabdoid” cells with brightly eosinophilic cytoplasm; large, eccentrically placed nuclei; and single, prominent nucleoli with or without fibrillary globoid inclusion. The clinical outcomes from ATRT often are poor and thus recognizing, and differentiating these tumors on imaging is important to help guide treatment, as aggressive management may help alter the course of this tumor. The purpose of this study is to review the imaging findings of patients with ATRT of the brain, through the review of imaging of a local case series, describe common and subtle features based upon our review.
Approach/Methods
The various imaging features of ATRT tumors are reviewed and presented. A retrospective review of a case series with descriptions of various pertinent appearances of an ATRT tumor will be presented.
Findings/Discussion
The imaging findings of ATRT are varied, and differentiating them from other more common or less aggressive lesions can be problematic. However early recognition is important as it can help guide towards aggressive clinical management.
Summary/Conclusion
Atypical teratoid rhabdoid tumors are aggressive and difficult to diagnose tumors of pediatric patients, with features similar to other lesions. Recognition of the varied and rare imaging findings can help guide early management decisions.

KEYWORDS: ATRT

eEdE-145

A Web-Based Mobile Application for Learning and Reviewing the Appearance of Pineal Gland Lesions Using a Multimodality Approach

Amin, V. B.·Chorney, E. T.·Sicular, S.·Ward, T. J.·Horn, C.·Kadoch, M. A.
Mount Sinai Medical Center
New York, NY.

Purpose
The purpose of the exhibit is: 1. To provide quick and easy access to a web-based mobile application and reference guide that addresses most of the common pineal gland lesions as evaluated by modern imaging modalities. 2. To provide a reference tool that addresses the limitations of other online reference tools, which can be cost-prohibitive, require log-ins or registration, lack interactivity, and often are slow to engage the end user. 3. To provide imaging of both the specific and nonspecific imaging features of a given pineal gland lesion. 4. To provide a novel learning platform that is fully functional using either the internet alone or on most major handheld devices and tablets, which are becoming increasingly important as educational resources for fellows, trainees, and students.
Approach/Methods
All pineal gland lesions encountered at our institution since 2001 were reviewed for potential inclusion in the exhibit.
Findings/Discussion
The major teaching points of this exhibit are: 1. Reviewing the diagnostic as well as nonspecific imaging findings of multiple pineal gland lesions on modern imaging modalities. 2. Encouraging each user to expand on this review by linking each pathology to important AJNR articles that further discuss that specific pathology. 3. Measuring the success of this electronic educational exhibit by monitoring number of online views and traffic directed towards the supplied AJNR articles.
Summary/Conclusion
A web-based mobile application for learning and reviewing the appearance of pineal gland lesions using a multimodality approach is presented.

KEYWORDS: Pineal gland, Neoplasm

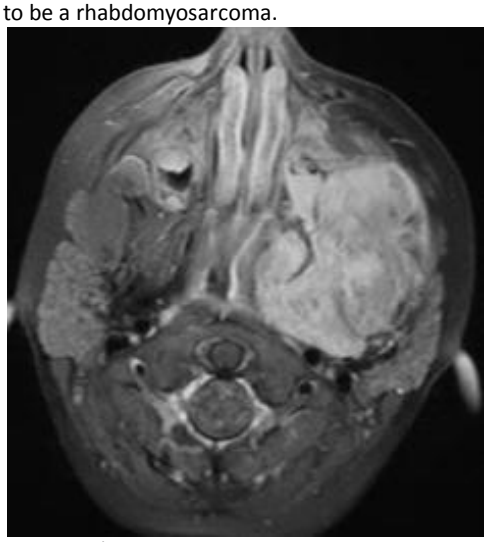
Imaging Review of Pediatric Head and Neck Neoplasms

Singh, A. K.[1]·Sato, Y.[2]·Sato, S.[2]·Tiwari, R.[3]
[1]University of Texas Health Science Center, San Antonio, TX, [2]University of Iowa Hospitals and Clinics, Iowa City, IA, [3]Bhopal Medical Center, Bhopal, INDIA.

Purpose
The purpose of this exhibit is to review the imaging appearance of pediatric head and neck neoplasms,

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

including in utero imaging.
Approach/Methods
We retrospectively reviewed the cases of pediatric and fetal head and neck neoplasms at our institution. The representative cases were selected and their images were used for this exhibit.
Findings/Discussion
Most of the head and neck lesions in the pediatric age group are of benign etiology like inflammatory and congenital lesions. Neoplasms are uncommon with only 5% of pediatric cancers arising in the head and neck region. These lesions are discussed with emphasis on the unique imaging features. Some of the examples are hemangioma, metastases, rhabdomyosarcoma, teratoma, juvenile angiofibroma, etc. Imaging not only helps in diagnosing these neoplasms but may help deciding the care of the patients. In the evaluation of fetal neck masses, MR is an important imaging tool which helps not only in the diagnosis but it also can evaluate the fetal airway compression which is essential in planning for EXIT (ex utero intrapartum treatment). Figure shows a large enhancing lesion in the left masticator space which proved to be a rhabdomyosarcoma.



Summary/Conclusion
Imaging plays a key role in the diagnosis of head and neck neoplasms in pediatric age group and during intrauterine life. It is essential to be familiar with the characteristic imaging appearance of these lesions which is the goal of this exhibit.

KEYWORDS: Rhabdomyosarcoma, Hemangioma

eEdE-147

Common and Uncommon Pediatric Temporal Bone Lesions: Case-Based Teaching File

Patel, R.[1,2]·Jacob, R.[1,2]·Booth, T.[1,2]
[1]Children's Medical Center, Dallas, TX, [2]University of Texas Southwestern Medical School, Dallas, TX.

Purpose
Temporal bone lesions in pediatric population can be commonly secondary to infection (mastoiditis) and Langerhans cell histiocytosis. Uncommon lesions like cholesteatoma, metastatic neuroblastoma and rhabdomyosarcoma are occasionally encountered. Rare lesions include benign lesions like aneurysmal bone cyst, melanotic progonoma, arteriovenous malformation and malignant lesions like osteosarcoma, Ewing's sarcoma and lymphoma. This electronic presentation outlines the following: 1. Review the clinical presentations of temporal bone lesions. 2. Review the imaging features of common and uncommon temporal bone lesions in children.
Approach/Methods
A retrospective search of PACS was performed on studies performed at the Children's Medical Center, Dallas for the last 10 years. Imaging studies depicting lesions in the temporal bone were identified. All studies were de-identified, prior to image export.
Findings/Discussion
Over 10 representative cases of the different temporal bone lesions including but not limited to Langerhans cell histiocytosis, cholesteatoma, mastoiditis, rhabdomyosarcoma, metastatic neuroblastoma, lymphoma, osteosarcoma, Ewing's sarcoma, aneurysmal bone cyst, melanotic progonoma were selected for inclusion.
Summary/Conclusion
Familiarity with the imaging features of temporal bone lesions helps formulate a reasonable differential diagnosis. The knowledge of uncommon lesions will help in broadening the differential and ensuring they are considered while formulating a diagnosis.

KEYWORDS: Pediatric neoplasms, Temporal bone

eEdE-148

Pediatric Sellar and Suprasellar Pathology: A Tour Beyond "SATCHMOE"

Parekh, N. D.[1,2]·Chang, J.[1]·Ryan, M.[2]
[1]Northwestern Memorial Hospital, Chicago, IL, [2]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL.

Purpose
Sellar/suprasellar abnormalities often are encountered in the pediatric population, but the spectrum of disease and implications for treatment and management differ significantly from the adult population. The purpose of this educational exhibit is to discuss an approach to imaging

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

this region in children, illustrate the normal development and anatomy, and review pathology present in the pediatric population, emphasizing the salient and differentiating imaging features.
Approach/Methods
1. Normal anatomy, embryology and development of the pituitary gland. 2. Diagnostic algorithm and optimization of computed tomography (CT) and MR imaging (MRI) techniques for imaging the sellar/suprasellar region. 3. Comprehensive review of the pediatric suprasellar/sellar pathology.
Findings/Discussion
Abnormalities of the sellar and suprasellar region can arise from many structures including the pituitary gland, infundibulum, hypothalamus, optic chiasm, or parasellar structures. Congenital abnormalities in this region are a particular concern in the pediatric population; pituitary hypoplasia or an ectopic posterior pituitary are rarely a consideration in the adult population, but can be critical for the appropriate growth and development of a child or adolescent. Empty sellas, though a common incidental finding in adults, are uncommon in children and may reflect intracranial hypertension. Additionally, some malformations - duplication of the stalk or absence of the optic chiasm - can be important indicators of more extensive midline abnormalities. Pediatric suprasellar lesions are predominantly neoplastic; although non-neoplastic, inflammatory, infectious and, rarely, demyelinating lesions also occur. Entities that are frequent concerns in adults, such as aneurysms, metastases or meningiomas, are rare in children; but other lesions such as craniopharyngiomas, germ cell tumors or Langerhans cell histiocytosis should be of greater consideration. Assessing the presence of the posterior pituitary bright spot also is important in assessing suprasellar and stalk lesions, and this can be optimized with specific imaging techniques, such as high resolution fat saturated T1 sequences to suppress any adjacent marrow fat. Intrasellar lesions such pituitary cysts or adenomas occur in children as in adults. However, in addition to special imaging techniques - dynamic contrast-enhanced imaging to unmask small lesions - knowledge of the vascularity in this region is important. Hypophyseal veins, rarely appreciated by imaging in adults, commonly are visualized in children and can be a source of false positives. Pituitary macroadenomas are rare in pediatrics, and often clinically evident, but their imaging appearance can be challenging in this population, especially since other cystic and solid lesions are more common.
Summary/Conclusion
A variety of lesions affect the sella and suprasellar region in the pediatric population. The frequency of disease differs significantly between adults and children. Metastases, aneurysms and other lesions commonly encountered in adults are typically only distant considerations in children, and thus popular adult mnemonics such as “SATCHMOE” should not be extrapolated to the pediatric population without consideration for the different prevalence of these lesions. Knowledge of the common pediatric lesions and their imaging appearance is important in generating meaningful and relevant diagnoses. Additionally, understanding the anatomy, embryology and differences in childhood disease also can help optimize the imaging technique in order to avoid pitfalls.

eEdE-149

Brain Destruction: Are Porencephaly, Cystic Encephalomalacia, Leucoencephalomalacia, Gliosis Synonyms?

Davila-Acosta, J. H.[1]·Miller, E.[1]·Hassan, D.[1]·Beltran-Marin, M.[2]
[1]Children Hospital of Eastern Ontario, Ottawa, ON, CANADA, [2]Erasme University Hospital, Brussels, BELGIUM.

Purpose
In neuroradiologic literature, there is a vicious use of terms that refer to differing patterns of brain damage or destruction. These differ largely in the pediatric and adult population with superimposed definition of the terms. This exhibit intends to: 1. Describe the pathophysiology of the different patterns of brain destruction at different ages and their long term result. 2. Provide a systematic definition of the patterns of brain destruction using pathology and imaging correlation. 3. Describe the relationship of the patterns of brain destruction with their causes and age of damage.
Approach/Methods
Depending on the etiology of an injury, age of occurrence of the event, severity and extension of the injury; different patterns of brain damage and destruction can affect the brain. We intend to review the pathologic definitions and findings of the main patterns of brain destruction and correlate with their imaging findings including porencephaly, hydrancephaly, cystic encephalomalacia, encephalomalacia, leucoencephalomalacia, gliosis, and others. The exhibit will present relevant information about the process of brain maturation including the differentiation and maturation of neuroblasts and oligodendrocites that play a key role in understanding brain injuries.
Findings/Discussion
Definitions of terms used to describe patterns of brain destruction are different among pathologists and radiologists. Through our review we will combine findings of pathology and imaging to clarify different entities and try to related the findings to causes, time of injury and outcome. The brain maturation process involves morphologic and brain composition changes. Morphologic changes include a decrease in the size of extraaxial and ventricular spaces and an increase in brain volume. Brain composition changes include changes in cellular density, increase in complex lipids content (myelination process),

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

decrease in free fluid white matter water content, developing white matter and cortical fiber network and neurotransmitters, and neurotransmitters-receptors interactions. One of the most important events that occurs during brain maturation is given by the immature oligodendrocytes which are actively reproducing and forming myelin. This has a poor reparative function in younger ages. These changes can explain why similar brain pathology can have varying characteristics at different ages and the differences observed in brain disease in neonates, infants and older children. Examples of the different characteristic pattern of brain disease can be seen in ischemic process, metabolic disease, cortical development malformations, infectious process, tumors and genetic disorders.

Summary/Conclusion

Understanding the brain maturation process can help to recognize the different patterns in brain destruction and brain damage. This information can help to recognize causes and etiology of injury.

eEdE-150

MR Imaging Evaluation of Head, Neck and Spine Masses in the Fetus

Mignone Philpott, C.[1]·Shannon, P.[2]·Chitayat, D.[2]·Ryan, G.[2]·Blaser, S.[1]
[1]Hospital for Sick Children, Toronto, ON, CANADA, [2]Mt Sinai Hospital, Toronto, ON, CANADA.

Purpose

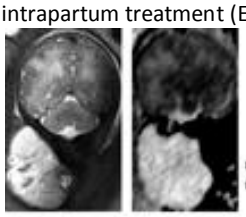
MR imaging is increasingly utilized to further evaluate cranial, neck and spine masses in the fetus. Our purpose is to illustrate the common tumors and tumor mimicks and their distinguishing imaging features, using conventional and advanced MR imaging (MRI) techniques and describe pertinent features to aid clinical management.

Approach/Methods

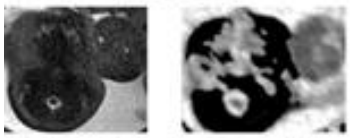
All fetal MRI cases of head, neck and spine masses performed in our institution were reviewed, in conjunction with follow-up postnatal imaging and pathologic correlation. Note was made of working diagnoses prior to and post MRI, and correlation made with final pathology diagnosis. We have reviewed other similar case series and case reports of fetal head, neck and spine masses, particularly those with pathologic correlation.

Findings/Discussion

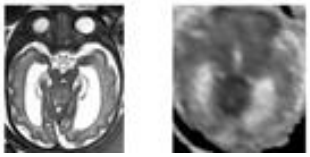
The most common masses of the spine are sacrococcygeal teratomas and in the neck, lymphatic malformations. Soft tissue sarcomas comprise the majority of malignant neck neoplasms. Heterotopic and benign cystic lesions are the most common intracranial masses, with malignancies, such as medulloblastoma, more rare. The distinction of potentially malignant from benign entities appears to be aided by use of diffusion-weighted imaging. We demonstrate the key imaging characteristics of these tumors and their mimics: including heterotopia and infarctions. Heterogeneity of the tumor (i.e., hemorrhage and calcified components) appear well illustrated on conventional and susceptibility-weighted techniques and such features aid differential diagnosis. There was a high correlation with the final pathology diagnosis in all our cases. MR imaging also provides good anatomical definition of the tumor, key to planning ex utero intrapartum treatment (EXIT) procedures.



Coronal T2, coronal DWI sequences: Cervical lymphatic malformation



Coronal T2, coronal DWI sequences: Facial myofibroma



Axial T2, DW sequences: Medullonastoma

Summary/Conclusion

MR imaging is an essential tool for further evaluation of fetal head/neck and spinal masses, including defining their anatomical relationship with surrounding structures and distinguishing intracranial tumors from benign or destructive pathology. We illustrate examples of commonly encountered entities and key imaging points for lesion characterization and diagnosis, paramount in antenatal management and counselling.

KEYWORDS: Fetal MR imaging, Masses, head, neck, spine

eEdE-151

Disorders of the Cranial Nerves in Pediatrics

Vossough, A.·Dahmoush, H. M.
Children's Hospital of Philadelphia
Philadelphia, PA.

Purpose

Disorders of the cranial nerves often are seen in pediatric neuroradiology. While there are some common etiologies of cranial nerve dysfunction among children and adults, many disorders typically are seen only in children or are diagnosed during childhood. Clinical manifestations referable to cranial nerves often are encountered in children. Magnetic resonance (MR) imaging of cranial nerve pathologic conditions is challenging because of the relatively small size of most nerves. Demonstrating subtle abnormalities of these small neural structures requires tailored studies focusing on the specific nerve(s) that need evaluation. This ultimately results in earlier and more

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

accurate diagnoses improving patient care. This educational exhibit will provide an illustrated review of a variety of cranial nerve conditions which predominantly present in the pediatric age group.
Approach/Methods
First, we will review briefly the various classes of thin-section high-resolution MR imaging techniques that will allow adequate visualization and evaluation of the cranial nerves in children. We then will review the various etiologies that are either uniquely or more commonly seen in children with cranial nerve dysfunction, using a systematic approach to each individual cranial nerve. Finally, we will discuss various disorders that often cause multiple cranial nerve disorders in children.
Findings/Discussion
Magnetic resonance imaging of pediatric cranial nerve pathologic conditions is challenging due to the relatively small size of most nerves. Demonstrating subtle abnormalities of these small neural structures requires tailored studies focusing on the specific nerve(s) that need evaluation. The use of focused high-resolution exams especially with use of higher field systems allows such assessment to be made in many instances. Various spin-echo and balanced gradient-echo techniques are available for optimal visualization of the cranial nerves in children. There are numerous etiologies of pediatric cranial nerve abnormalities. Congenital abnormalities specific to individual cranial nerves, including absence or hypoplasia of the nerve, either in isolation or as part of genetic or syndromic conditions commonly are seen in children. There can be involvement of the cranial nerves by demyelinating, inflammatory, metabolic, degenerative, or infectious processes that commonly affect children. Many cranial nerve-related masses also classically present in the pediatric population. Vascular variants and anomalies resulting in cranial nerve dysfunction can be seen in children. Various metabolic and multisystem disorders can involve multiple cranial nerves in children.
Summary/Conclusion
Disorders and abnormalities of the cranial nerves which commonly or exclusively present in the pediatric population will be demonstrated in this educational exhibit. This will include congenital, demyelinating, inflammatory, metabolic, degenerative, infectious, neoplastic, and vascular lesions. Tailored studies directed by the clinical presentation are important in delineation of the symptomatic cranial nerve and familiarity with such abnormalities can provide an important role in the overall management of these children.

KEYWORDS: Cranial nerves, Cranial nerve pathology

eEdE-152

Fetal MR Imaging: A Valuable Tool in Evaluation of Fetal Brain Pathology

Yazbek, S.[1]·Allmendinger, A.[2]·Grant, P. E.[1]
[1]Boston Children's Hospital, Harvard Medical School, Boston, MA, [2]Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Purpose
Obstetrical ultrasound remains the primary screening technique for the fetal central nervous system (CNS). However, over the last two decades, MRI has proven to be an extremely useful adjunctive tool in evaluating the developing brain.
We will describe the advantages of fetal MRI by exposing the findings of different CNS abnormalities on fetal MRI and on obstetrical ultrasound.
Approach/Methods
Abnormal fetal brain MRIs that were performed in our institution over a two-year period (2010-2012) were reviewed. The studies were performed on a 1.5T magnet and included multiplanar SSFSE T2, FIESTA, T1, T2* and diffusion-weighted images. We start by discussing the safety of MRI in pregnancy, its limitations and the different sequences and new techniques developed in fetal MRI. We then describe the different CNS pathologies encountered on fetal MRI and compare, in each case, the anomalies delineated on the MRI to the pathology demonstrated on an obstetrical ultrasound done the same day. We also compare the findings of the fetal MRI to the findings of a postnatal brain MRI when this is available.
Findings/Discussion
With respect to potential teratogenicity, the majority of reports suggest that MR is safe in the fetus. Fetal MRI is preferably performed after the first trimester, after organogenesis has occurred. MR imaging usually is performed on 1.5T scanners with ultrafast MR imaging techniques to reduce the likelihood of fetal movement during acquisition. MR imaging provides excellent image contrast by exploring multiple tissue properties such as T1 and T2. MR imaging also provides an assessment of diffusion changes, and can show changes over time in various metabolites in the brain through the use of MR spectroscopy. Diffusion tensor imaging and fMRI have been performed successfully in late gestation pregnancies when the fetal head is engaged in the maternal pelvis and relatively immobile. Fetal MRI permits prenatal evaluation of multiple CNS abnormalities. Examples of pathology illustrated include ventriculomegaly, aqueductal stenosis, interhemispheric cysts, posterior fossa abnormalities, corpus callosum abnormalities, cortical malformations, intracranial hemorrhages, infarctions, tuberous sclerosis, aicardi syndrome, piriform aperture stenosis, hemimegalencephaly, vascular malformations, chiari malformations as well as head and neck anomalies including cleft lip and palate. Fetal MRI allowed a better delineation of brain abnormality demonstrated on an

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

obstetrical ultrasound done the same day and, sometimes, allowed finding additional anomalies. These anomalies were confirmed on the postnatal MRI, which also provided further evaluation and extra information.
Summary/Conclusion
This review illustrates the important value of MRI in the evaluation of fetal brain abnormalities and its significant role in prenatal counseling. Technical advances in MRI will further improve the evaluation of fetal brain. However, since fetal MRI usually is performed when an abnormality is suspected on the ultrasound or in case of prior abnormal pregnancy, a large number of “real” normal control fetal MRIs is not available. This is why, early diagnosis of some subtle brain abnormalities remains challenging.

KEYWORDS: Fetal MR imaging, Ultrasonography, brain

Double Trouble. . . Occam's Razor Does Not ALWAYS Cut It!"

Mirsky, D. M.[1]·Bello, J. A.[2]
[1]Children's Hospital Colorado, Aurora, CO, [2]Montefiore Medical Center, Bronx, NY.

Purpose
Beyond the scope of "incidental findings", more than one finding may be apparent on a neuroimaging study. When two or more such findings are made, they may be viewed as being clinically significant or insignificant. Our goal is to present cases with dual distinct pathology that may be related and how to approach such cases in order to provide appropriate recommendations for followup.
Approach/Methods
Cases of dual (or more) pathology were collected from inpatient and outpatient imaging sources in both pediatric and adult populations. The cases were researched for clinical relevance of the multiple findings and recommended followup. In each case the findings were categorized according to their significance and relationship. The dual pathology was further categorized as: - distinct, but related (NF with optic glioma and "white spots"). - distinct and unrelated (glioblastoma and AVM). - distinct and possibly related (meningioma and white matter signal . . uncommon edema, venous congestion).
Findings/Discussion
A spectrum of distinct pathologies encountered on a single imaging study are reviewed. Various subtleties are presented and discussed in the context of their clinical significance and providing useful follow-up recommendations.
Summary/Conclusion
It is not uncommon for more than one finding to be discovered on a neuroimaging study. The difficulty that arises is trying to determine whether the findings are related and clinically significant or insignificant. The true challenge arises when one is faced with dual pathologies that are unrelated or not obviously related and how to handle such cases. At a time when imaging and reporting efficiency are paramount to streamlining healthcare, we present several examples of such cases, with recommendations for appropriate followup.

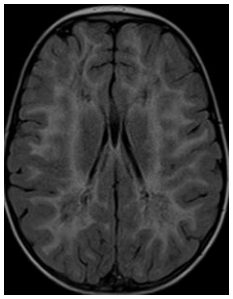
KEYWORDS: Incidental findings

eEdE-154

Imaging Spectrum of Encephalopathy in Children

Singh, A. K.[1]·Bathla, G.[2]·Sato, Y.[2]·Tiwari, R.[3]
[1]University of Texas Health Science Center, San Antonio, TX, [2]University of Iowa Hospitals and Clinics, Iowa City, IA, [3]Bhopal Medical Center, Bhopal, INDIA.

Purpose
The purpose of this exhibit is to review the imaging spectrum of encephalopathy in children.
Approach/Methods
We retrospectively reviewed the cases of encephalopathy in children with different etiologies and their representative images were used for this exhibit.
Findings/Discussion
Pediatric encephalopathy is an uncommon condition but it is associated with significant morbidity and mortality. There are different causes of encephalopathy in children which can be grouped into multiple categories like infections, toxic, metabolic, hypoxia, seizure, tumors, etc. These entities with their imaging features are discussed in this exhibit. Some of the examples are hypoglycemic encephalopathy, hypoxic-ischemic encephalopathy, kernicterus, MELAS, metastatic disease, herpes encephalitis, etc. Early diagnosis in these conditions is extremely important for proper management. Figure shows diffuse high FLAIR signal in the bilateral white matter in a patient diagnosed with methotrexate induced leukoencephalopathy.



Summary/Conclusion
Imaging plays a key role in the management of pediatric encephalopathy and the radiologist may be the first one to suggest accurate diagnosis. It is essential to be familiar with the imaging appearance of different causes of pediatric encephalopathy which is the goal of this exhibit.

KEYWORDS: Encephalopathy

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

eEdE-155

Common and Uncommon Imaging Manifestations of Langerhans Cell Histiocytosis in Children

Shifrin, A.[1]·Nabavizadeh, S. A.[2]·Feygin, T.[2]·Pollock, A. N.[2]·Vossough, A.[2]·Zimmerman, R. A.[2]
[1]Mount Auburn Hospital, Cambridge, MA, [2]The Children's Hospital of Philadelphia, Philadelphia, PA.

Purpose
To illustrate the spectrum of common and uncommon imaging manifestations of Langerhans cell histiocytosis (LCH) in children.
Approach/Methods
At our institution, imaging of suspected LCH in the brain, head, neck, and spine is performed either on MRI or CT and, in select cases, on US. MR imaging is performed using 1.5 or 3.0T magnets. Our protocols include T1- and T2-weighted, postcontrast thin sections through the region of interest in orthogonal planes, as well as diffusion-weighted imaging.
Findings/Discussion
The spectrum of common and uncommon imaging findings in multiple patients with LCH lesions will be illustrated. A wide variety of lesion locations includes the brain, head, skull base, neck, and spine. Special attention will be given to imaging techniques, including diffusion-weighted imaging, and the pathophysiology of LCH lesions. Additionally, several imaging findings not previously established as characteristic of LCH, including presence of restricted diffusion and fluid-fluid levels, will be described.
Summary/Conclusion
Langerhans cell histiocytosis can present with variable clinical and imaging manifestations, and familiarity with different patterns of this entity is necessary for timely and accurate diagnosis.

KEYWORDS: Langherans cell histiocytosis, Pediatric brain

eEdE-156

Neuroimaging in Tuberous Sclerosis Complex: Highlighting Changes in Cerebellar Tubers

Banker, P.·Rodrigues, D.·Salamon, N.
University of California Los Angeles
Los Angeles, CA.

Purpose
To describe cases of tuberous sclerosis complex (TSC) with cerebellar lesions that experienced changes in signal and morphology over time, including development of neovascularization, suggesting an alternate pathogenesis of cerebellar tubers that differs from the natural course of cerebral tubers.
Approach/Methods
A retrospective review of MR imaging (MRI) from 61 pediatric and young adult patients with TSC found 15 patients with cerebellar lesions (24.6%). Followup was obtained in 13 of the 15 patients (86.7%), mean age of 6.7 years at initial imaging and 14.3 years to final imaging. During a mean follow-up period of 7.6 years, an average of 7.1 MRI studies were performed. Four of the 13 patients had bilateral cerebellar tubers, accounting for a total of 17 lesions. Of the 17 total cerebellar tubers in the 13 patients, six underwent change over time (35.3%, 46.2% respectively). Amongst the six tubers that changed over time, the majority showed neovascularization, calcification, enhancement, T2/FLAIR hyperintensity, and focal parenchymal atrophy with time. One cerebellar tuber ultimately hemorrhaged after developing a prominent adjacent cortical vessel.
Findings/Discussion
Tuberous sclerosis complex is an inherited systemic disease with prominent CNS, cutaneous, and visceral manifestations. Cerebellar tubers have been described in 24%-28% of cases. While Vaughn et al have described these tubers to change with time, the development of adjacent vascularity and propensity for bleeding has not been reported. The majority of the cerebellar tubers that were followed up underwent neovascularization, calcification, and focal cerebellar atrophy. Neovascularization was seen in 11/17 (64.7%), calcification in 10/17 (58.8%), parenchymal atrophy in 17/17 (100%), enhancement in 7/17 (41.2%), and high T2/FLAIR signal in 14/17 (82.4%) of the cerebellar tubers. Hemorrhage within a cerebellar tuber was observed in one patient, described below. MR imaging of the brain in one particular patient at the time of presentation demonstrated at least 25 cerebral tubers, bilateral subependymal nodules, and a right cerebellar tuber. His right cerebellar tuber initially showed T1 hypointensity, T2/FLAIR hyperintensity, enhancement, but no calcification or prominent cortical vessels. Over time, this lesion developed a new cortical vessel, adjacent focal parenchymal atrophy, and calcification. This lesion ultimately hemorrhaged on his final follow-up MRI.
Summary/Conclusion
Tuberous sclerosis complex is a unique neurophakomatosis with diverse manifestations. We describe specific progressive changes in cerebellar lesions in TSC and propose that these changes may have prognostic importance, especially in the setting of neovascularization and hemorrhage. Unlike the cerebral tubers, which tend to remain stable, the morphologic evolution of cerebellar tubers suggests that an alternate pathogenesis may play a role in the development of these lesions.

eEdE-156a

Pediatric Leukodystrophies: Utilizing Diffusion-Weighted Imaging and MR Spectroscopy to Refine the Conceptual Approach

Allmendinger, A.[1]·Viswanadhan, N.[1]·Yazbek, S.[2]·Prahbu, S.[2]
[1]Brigham and Women's Hospital, Harvard Medical School, Boston, MA, [2]Boston Children's Hospital, Harvard Medical School, Boston, MA.

Purpose
Pediatric leukodystrophies are complex group of diseases that result from abnormal primary myelination or secondary myelin/neuronal degeneration. MR imaging is now the modality of choice for detecting these white matter disorders; however, findings may be nonspecific with the use of conventional MR sequences. We will provide a systematic clinical-radiologic conceptual approach to pediatric leukodystrophies, and present cases of specific disorders with specific patterns of abnormality. In addition, we will elaborate the use of MR spectroscopy and diffusion-weighted imaging in the diagnostic algorithm, along with key clinical features that aid in making a more specific diagnosis, or at least narrow the differential diagnoses.
Approach/Methods
Imaging studies obtained for pediatric patients with proven pediatric white matter disease from our tertiary care institution over an eight-year period (2004 -2012). MR images were obtained on both 1.5 and 3T magnets (majority on 3T). We illustrate the diagnostic workup with emphasis on the utility of diffusion-weighted imaging and MR spectroscopy. We describe important imaging features of each disease narrowing the differential diagnosis of this complex group of diseases, which guides the radiologist and clinicians in planning the most appropriate workup and tailor laboratory tests, ultimately reducing overall costs and ensuring more prompt diagnosis.
Findings/Discussion
Use of a conceptual approach in conjunction with the clinical features can help narrow the differential diagnosis in these patients. In this clinical-radiologic approach, we divide the disorders into groups based on the relative degree of involvement of the gray and white matter, exact distribution of the abnormality, age of onset, head size, nature of lesions, organ and skeletal involvement, neurologic features and degree of temporal progression. MR spectroscopy and DWI data is merged with the structural and clinical characteristics to help refine the diagnosis pathway. Examples of grouped disorders include leukodystrophies presenting with macrocephaly, gray matter involvement with and without visceral storage, predominant white matter involvement, combined gray and white matter involvement, neonatal disorders mimicking gray matter degeneration (subdivided into epileptic syndromes, metabolic disorders and other deficiencies). Specific diagnostic patterns are seen in patients with metachromatic leukodystrophy, globoid cell leukodystrophy, Saposin B deficiency, Canavan disease, Alexander disease, Sulfite Oxidase deficiency, Leigh syndrome, glutaric aciduria Type-1, hydroxyl-glutaric aciduria, Pelizaeus-Merzbacher disease and mitochondrial encephalopathy, lactic acidosis, with stroke-like episodes (MELAS), hypomyelination with basal ganglia atrophy, LBSL, megalencephalic leukoencephalopathy with cysts, pyruvate carboxylase deficiency, fucosidosis, X-Linked adrenoleukodystrophy and maple syrup urine disease (MSUD). We emphasize utility of diffusion-weighted imaging and MR spectroscopy in diagnosing some of these conditions. We also highlight potential pitfalls in the diagnosis of these disorders, challenges in classifying more rare disorders and mention possible solutions for future research.
Summary/Conclusion
This review illustrates the value of the combined clinical and radiologic approach to pediatric leukodystrophies. We highlight specific MRI patterns of numerous common and unusual white matter diseases and provide a structured algorithm to aid in narrowing the differential, and in some cases, make an accurate, initial diagnosis. We show how judicious use of MR spectroscopy and diffusion-weighted imaging can help refine the diagnostic algorithm.

NeuroRads.org: Integrating ASNR Resources with the ABR Core Exam of the Future

Kadoch, M. A.·Rydzinski, Y.·Horn, C.·Sicular, S.·Ward, T. J.·Cohen, M. G.
Mount Sinai Medical Center
New York, NY.

Purpose
The purpose of the exhibit is to present an educational resource to aid radiology residents preparing for the new ABR core exam. ASNR resources (AJNR, Neurographics, Case of the Week, etc.) are an invaluable resource for young trainees who may not yet be aware of their utility for board exam preparation. NeuroRads.org will integrate these resources with the specific neuroradiology expectations of the new ABR core exam as outlined in the official ABR core exam study guide. In addition, several web-based mobile applications will provide the user with opportunities to review the major imaging features of the most commonly tested entities.
Approach/Methods
All ASNR resources (AJNR, Neurographics, Case of the Week, etc.) were surveyed exhaustively for integration with the official ABR Diagnostic Radiology Core Examination Study Guide. Select cases from our institution were included in the development of web-based mobile applications.
Findings/Discussion
Neuroradiology training finds itself at a pivotal crossroads, with the ABR Core Exam of the Future expected to debut in the fall of 2014. It is critical that invaluable ASNR resources are not overlooked by young trainees who will be preparing for the new board examinations. By integrating the most relevant of these resources with the ABR's new exam expectations, the next generation of radiologists will be exposed to the outstanding educational resources available through the ASNR.
Summary/Conclusion
NeuroRads.org will integrate ASNR resources with the ABR core exam of the future to ensure that the next generation of young radiologists preparing for board examinations are exposed to the outstanding educational resources available through the ASNR.

KEYWORDS: Neuroradiology training

Infinitely Variable On-the-Fly Real-Time Planar Interrogation of Volumetric CT and MR Imaging Data Sets Using Off-the-Shelf Game Controllers

Brunberg, J. A.[1]·Seibert, T.[1]·Teistler, M.[2]
[1]University of California Davis, Sacramento, CA, [2]Flensburg University of Applied Sciences, Flensburg, GERMANY.

Purpose
Currently available CT and MR imaging protocols allow for the derivation of high-resolution image data with isometric voxel dimensions. The interrogation of these 3D image data sets using fixed orthogonal planes, or single angulated planes, is, however, frequently insufficient for an optimal characterization of imaging findings. The purpose of this exhibit is to demonstrate the development of a small hand-held ultrasound-like probe that allows for on-the-fly infinitely adjustable interrogation of an MR or CT imaging data set in real time.
Approach/Methods
Software has been programmed to integrate with inexpensive computer game controllers, allowing for on-the-fly interrogation of high resolution volumetric CT or MR image data sets in a manner similar to the strategies used for a clinical ultrasound imaging procedure.
Findings/Discussion
These software and hardware adaptations allow for a more definitive observer-defined characterization of normal and abnormal structural relationships within the spine, within the head and neck, within orbits, and within the cranial vault. Regions of interest that are obscured by normal oblique relationships, by structural pathology, or by rotation or asymmetric patient positioning during CT or MR image acquisition, can be reformatted immediately and anatomically characterized. A software-enabled standard PC computer and game controllers will be available for demonstration.
Summary/Conclusion
The ability to achieve on-the-fly infinitely variable reformatted planar anatomical imaging improves the utility of volumetric CT and MR imaging data for the characterization of normal and abnormal structural findings. Versatility, low cost and clinical utility suggest that this capability should be incorporated as a routine tool that is available for diagnostic use in association with the radiologist's PACS workstation.

eEdE-159

Self-Plagiarism in the American Journal of Neuroradiology versus Radiology: An Evaluation Using iThenticate

Kalnins, A. U.[1]·Chin, M.[1]·Halm, K.[2]·Castillo, M.[1]
[1]University of North Carolina at Chapel Hill, Chapel Hill, NC, [2]American Journal of Neuroradiology, Oakbrook, IL.

Purpose

Plagiarism is thought to be commonly encountered in medical journals. Multiple sporadic, similar phrases may be identified synthesizing what has been previously written and most editors accept this practice. Copying entire sections from prior manuscripts is, however, considered plagiarism. In order to evaluate similarities in academic work, programs such as iThenticate cross-reference manuscripts against databases of publications. The American Journal of Neuroradiology (AJNR) randomly uses iThenticate to evaluate 25% of published manuscripts/year for potential overlap. However, it is not clear if the program should be used to evaluate for plagiarism in all submissions. In order to review the scope of potential plagiarism, we analyzed all original research articles published in AJNR and Radiology in 2011 and randomly chose two AJNR issues from 2012 using iThenticate. Our goals were: to assess whether analyzing two randomly chosen issues from one journal provides similar information to analyzing an entire year, and to see if significant duplications are more common in a specialty journal (AJNR) or a general journal (Radiology).

Approach/Methods

All original research articles from AJNR and Radiology in 2011 were cross-referenced with those contained in the iThenticate publication database. We arbitrarily chose a 15% threshold for duplicated content and when it was exceeded, two individuals assessed the similarities and assigned them significance (sporadic phrases vs. large sections, the latter implying plagiarism). Two randomly chosen AJNR issues in 2012 (March, September) also were evaluated for similarities and differences with the statistical results obtained for the entire 2011 volume of AJNR.

Findings/Discussion

Table 1

	AJNR 2011*	AJNR Mar	AJNR Sep 2012
Number of original research articles per issue and standard deviation	27.45 (2.73)	25	27
Number of articles with >15% total overlap per issue	4.91 (1.92)	5	4
Number of articles with >15% overlap from a single source	1.09 (1.04)	3	1
Number of articles with significant overlap per issue	0.18 (0.40)	0	0

*Average number of articles per issue

Table 2

	AJNR 2011	Radiology 2011
Number of scientific research articles in 2011	302 from 11 issues, 27.5 per issue	343 from 12 issues, 28.6 per issue
Number of articles with >15% similarity	54 (17.9% of total articles)	12 (3.5% of total articles)
Number of articles with >15% similarity from a single source	12 (4.0% of total, 22.2% of articles with >15% similarity)	2 (0.6% of total, 16.7% of articles with >15% similarity)
Number of articles with significant overlap	2 (0.66% of total articles, 16.7% of articles with >15% similarity from a single source)	1 (0.29% of total articles, 50% of articles with >15% similarity from a single source)

Summary/Conclusion

Using our empiric 15% threshold, the number of articles found to have significant duplicated content was low for both AJNR and Radiology (0.66% vs. 0.29%). When the original research articles published in AJNR and Radiology in 2011 were evaluated for significant similarities, only two articles in AJNR and one in Radiology were deemed to have significant overlap with prior publications, in all instances judged as self-plagiarism. While AJNR had a greater percentage of articles demonstrating a greater than 15% overlap with prior publications when compared to Radiology, most were considered not significant. Additionally, analyzing two randomly chosen issues of AJNR yielded no significant differences in articles with >15% duplications when compared with those published during one entire year.

Collaborative Web-Based Platform for the Creation of Diagnostic and Clinical Management Algorithms

Gibson, D.[1]·Bonneville, F.[2]·Belden, C.[3]·Wippold, F.[1]
[1]Mallinckrodt Institute of Radiology, St. Louis, MO, [2]Hôpital de Rangueil, Toulouse, FRANCE, [3]Dartmouth-Hitchcock Medical Center, Lebanon, NH.

Purpose

Emerging challenges for 21st century neuroradiology focus on resource utilization and decision support in an era of changing models of reimbursement, increasingly complex imaging studies and ever-expanding body of scientific literature.

Approach/Methods

Neuroradiology must adapt to these challenges and

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

provide visionary leadership in the development of the content and context of objective measures of health care delivery. Towards this end, we have developed a web-based platform comprised primarily of 1) an intuitive graphical user interface allowing the creation of evidence-based clinical pathways and/or diagnostic algorithms within the context of a large scale relational database 2) network functionality for purposes of collaboration within recognized institutional or subspecialty frameworks, and 3) a filtered web and biomedical search engine facilitating rapid access to the most relevant clinical content. As an educational tool, the platform can supplement neuroradiologic training by providing searchable algorithms which may be used to generate more narrowed differential diagnoses than the traditional "gamuts" or location-based mnemonics.

Findings/Discussion

The platform also provides a means for neuroradiologists to collaborate with clinical colleagues in designing clinical pathways that guide rational usage of imaging resources, which is a high priority in accountable care reimbursement systems. With ultimate integration into electronic health record(s), diagnostic algorithms will be measured for accuracy as determined by pathologic diagnosis, thus creating the potential for data-driven probabilistic differential diagnoses in the future. Similarly, the quality of care pathways will be judged on clinical outcomes, measures of efficiency, and patient satisfaction.

Summary/Conclusion

We believe that by providing a transparent framework in which to measure the value of neuroimaging, we will preserve access to these often life-saving technologies, justify the large scale investments required for continued innovation, and more importantly provide the level of quality healthcare our patients deserve.

KEYWORDS: Quality improvement, Cost-effective, decision support

eEdE-161

CT Dose Measurement and Dose Reduction Strategies: A Primer and Self-Assessment for Neuroradiologists

Sampathu, D. M.·Mamourian, A. C.
Hospital of University of Pennsylvania
Philadelphia, PA.

Purpose

Surveys have demonstrated repeatedly that physicians have difficulty accurately predicting both the magnitude and relative radiation exposure of radiology exams. Furthermore, in spite of their training in medical physics, radiologists also have difficulty describing the radiation dose of common CT exams. As a result of the increasing utilization of CT exams, patients have become more knowledgeable and concerned about the potential for adverse effects from radiation. Given these dynamics, it is imperative that neuroradiologists become familiar with the language of radiation dose and understand the physics underlying modern multidetector scanners and new radiation dose reduction strategies.

Approach/Methods

This exhibit reviews basic terminology and definitions pertaining to radiation dose, summarizes the dose of common neuroradiologic CT exams, and explains the factors that contribute to it. Dose reduction strategies which can be introduced readily into daily practice are reviewed. A self-assessment tool is included in order to reinforce key facts and concepts; this tool has the potential to be adapted into a self-assessment module (SAM).

Findings/Discussion

The methods used to estimate CT radiation dose, including the common units of measurement such as CTDIvol and DLP are reviewed. The concepts of “absorbed dose” and “effective dose” are illustrated with images showing immediate and long-term adverse radiation effects. Typical radiation doses, expressed in mSv and DLP, associated with common neuroradiologic CT exams are summarized in a fashion to make them easy to recall. For example, a routine head has an effective dose that is less than background radiation in the USA and DLP of approximately 1000 mGy/cm. Next, the effects of varying CT scanning parameters such as kVp, mAs, pitch, and collimation on patient dose using a multidetector scanner are explained along with the rationale for adjusting these parameters based on patient attributes and desired dose limits. For example, the concepts of over-beaming and over-ranging are reviewed to explain why early single slice scanners, while now outdated, were surprisingly dose efficient. CT scanner hardware and reconstruction

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

techniques, including iterative reconstruction, are reviewed with regard to their effects on patient dose and perceived image quality.
Summary/Conclusion
As both the utilization of CT exams and the broad awareness of potential adverse effects of medical radiation increase, it is essential that neuroradiologists understand both CT scanner principles and radiation physics. This exhibit provides a concise review of the terminology of dose, CT hardware and techniques, and radiation dose reduction strategies that should be of value as we all strive to create diagnostic images at the lowest possible dose.

Intraspinal Masses: Don't Forget Sequestered Disk Fragment

Green, D. B.·Coopersmith, H.
North Shore University Hospital
Manhasset, NY.

Purpose
1. Review the evolution of disk herniation from bulge to sequestered fragment. 2. Illustrate the similar imaging findings of sequestered disk fragments and other spinal pathology. 3. Demonstrate the importance of recognizing a possible sequestered disk fragment.
Approach/Methods
We present a series of sequestered disk fragments from our institution and list a differential diagnosis for each case. A companion case of each item of the differential diagnosis then will be shown to highlight the differences and similarities in imaging findings.
Findings/Discussion
Sequestered disk fragments will be compared with meningioma, schwannoma, metastasis, nerve sheath tumor, epidural abscess, epidural hematoma, complex facet cyst, and scar tissue. Important features include location, morphology, signal characteristics, and presence of enhancement. Symptoms and patient history also will be considered, and potential differences in patient management will be discussed.
Summary/Conclusion
Sequestered disk fragments are rare and frequently overlooked but can mimic other spinal pathology and cause similar symptoms. Consideration of sequestered disk fragments as part of a differential diagnosis can impact patient management, surgical planning, and patient outcomes.

eEdE-163

Nuclear Medicine for the Evaluation of Spine Infections: A Multimodality Review with MR Imaging and Pathologic Correlation

Sabby, T. L.·Hunt, C. H.·Diehn, F. E.
Mayo Clinic
Rochester, MN.

Purpose
The purpose of the exhibit is to: 1) Review the common nuclear medicine imaging studies used to image spine infections; 2) Correlate findings on these studies with those seen on MRI and at pathology; 3) Discuss the limitations related to nuclear medicine imaging of the spine and how to avoid potential pitfalls.
Approach/Methods
After a short review of the nuclear medicine options for imaging spine infections, a case series of patients will be presented demonstrating the utility of scintigraphy with and without SPECT/CT for the evaluation of spine infection. This series also will include cases which demonstrate the limitations of nuclear medicine, with emphasis on sources for both false negative and false positive results. All studies will be correlated with conventional imaging (CT, MRI) and pathologic findings.
Findings/Discussion
Nuclear medicine can be an effective tool when trying to problem-solve difficult spine infection cases. In addition to being available to patients who may not be able to undergo MRI, scintigraphy (especially with SPECT/CT) can help triage select patients appropriately and guide biopsies. Nevertheless, a thorough understanding of the potential pitfalls is needed in order to optimize patient management.
Summary/Conclusion
Nuclear medicine can provide significant added value to the evaluation of spine infections in select cases. The combination of scintigraphy with SPECT/CT, CT, and MRI is

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

a powerful imaging tool. However, careful understanding of the limitations of scintigraphy in this setting is needed to avoid misinterpretation of findings.

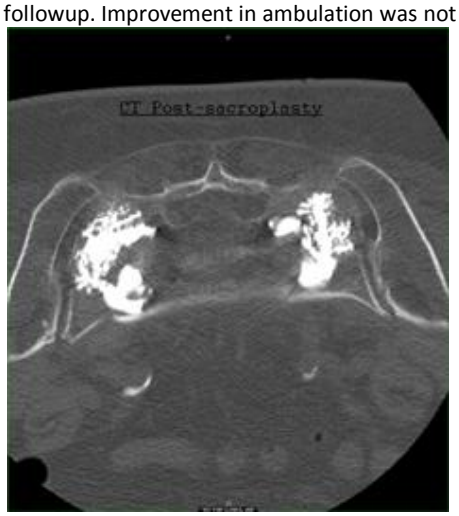
KEYWORDS: Spinal imaging, Infections

eEdE-164

CT Sacroplasty for Treatment of Painful Sacral Fractures

Borowski, A. M.·Olmsted, J. E.·Thompson, P.
Providence Health Center
Waco, TX.

Purpose
Sacral insufficiency fractures (SIF) can be a source of significant low back and pelvic pain in the elderly population. Percutaneous sacroplasty is being advocated as a relatively safe and effective image-guided procedure for treatment of the pain and disability associated with these fractures. We have embraced this technique to treat our patients, and present our experience in performing these procedures with conscious sedation, utilizing CT guidance.
Approach/Methods
During the past 24 months, 15 patients were referred to our facility for treatment of painful sacral vertebral fractures. Fracture acuity was documented by clinical history, and concurrent CT or MRI studies of the sacrum. Treatment was performed by interventional radiologists, utilizing conscious sedation. These patients usually are elderly, with multiple co-morbidities, so minimal sedation was used. Typically, 25mg Benadryl (IV), and 50-100 micrograms Fentanyl (IV) were adequate. Sometimes, Versed (Midazolam), also was given (0.5-1.0 mg). Surgery was performed with the patients in prone position, under CT guidance. Polymethyl methacrylate (PMMA) bone cement was injected through either 11 or 13 gauge needles. Procedure termination points were either dense opacification of the sacral ala, extra-osseous PMMA extrusion, or migration of the bone cement into adjacent neuro-foramina. Clinical followup was performed postoperatively by the attending physician, and delayed followup was provided by our clinical nurse co-ordinator, using telephone interviews and a standardized visual analog pain scale (VAS).
Findings/Discussion
Of the 15 patients treated, 14 had documented osteoporosis. This, along with clinical history, suggested benign insufficiency as the etiology of their fractures. One patient had a known diagnosis of multiple myeloma. Average age was 74.5 (range 55-96). All 15 patients were female. The average procedure time was 50.4 minutes (range 18-86 minutes). Treatment was bilateral in 13 of the 15 patients. Only two patients had unilateral fractures augmented. Eleven patients had significant improvement within 24 hours (greater than 5 points on subjective VAS). Two patients had moderate relief after severn-day followup (3-5 points), one patient died later (unrelated to the surgery) without significant relief, and one was lost to followup. Improvement in ambulation was not assessed.



Summary/Conclusion
Percutaneous CT-guided sacroplasty seems to be an effective, time and cost-efficient means of pain reduction with the appropriate sub-set of patients. We have had very promising results over these past two years, and hope that this treatment algorithm continues to help our patients have a more productive and pain-free life-style in the future.

KEYWORDS: Sacroplasty, CT-guidance, fracture

eEdE-165

A Cross-Platform Mobile Web Application for Learning and Documenting Competency in Neuroradiology Procedures

Stein, J. M.·Mohan, S.
Hospital of the University of Pennsylvania
Philadelphia, PA.

Purpose
Learning and demonstrating competency in routine procedures is an important part of radiology training at the residency and fellowship levels. The smartphones and other mobile devices that many trainees already carry could be used to facilitate learning and rapid documentation of procedural experiences.
Approach/Methods
Using free and open source components, we developed a mobile web application to facilitate learning and documenting competency in fluoroscopy-guided lumbar puncture and myelogram procedures. The application uses the Sencha Touch JavaScript framework to mimic a native application on iPhone, Android and Blackberry smartphones as well as the Apple iPad and other tablets. It also runs on Mac and Windows desktop computers. The application presents a step-by-step guide for each procedure with illustrative figures and anatomical images as well as space for user notes. It incorporates a time-

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

stamped procedure log with appropriate fields for procedure type, accession number, attending radiologist, complications, and other comments. Importantly, the application also includes evaluation forms that can be completed easily and electronically signed by the attending radiologist. The procedure log and attending assessment data may be stored locally or remotely. Finally, a summary page presents a graphical representation of procedures performed and trends and averages with respect to fluoroscopy time. This data can be made available to the program director for comparison across trainees. We are in the process of piloting the use of this application for training in our own department.
Findings/Discussion
Documenting procedural experience is necessary for radiology licensing and will be a focus of the new ACGME milestones for resident education in diagnostic radiology. Our application enables these activities to be rapidly documented at the time and location they are performed. By incorporating step-by-step reference guides, a procedure log, attending assessment and review into a single platform, the application should aid learning and help to ensure complete documentation. The application could be expanded to include additional procedures performed in neuroradiology as well as other radiology subspecialties.
Summary/Conclusion
A cross-platform application for mobile devices can be created to facilitate learning and documenting competency in neuroradiology procedures.

KEYWORDS: Lumbar puncture, Educational, mobile

eEdE-166

Dual Energy CT Imaging for the Spine

Khorrami-Arani, N.[1]·Liang, T.[2]·Shewchuk, J.[1]·Nicolaou, S.[1]
[1]Vancouver General Hospital, Vancouver, BC, CANADA,
[2]University of British Columbia, Vancouver, BC, CANADA.

Purpose
Dual-energy CT (DECT) refers to the simultaneous acquisition of low and high voltage CT data (most commonly 80 and 140 kVp), and is a technological advancement of CT for which multiple chest and abdominal imaging applications have been demonstrated previously. The purpose of this exhibit is to review the principles of DECT and review and demonstrate examples of the potential applications of DECT for imaging of the spine.
Approach/Methods
A retrospective review of patients scanned by the DECT spine protocol at our institution will be conducted for imaging examples.
Findings/Discussion
This educational exhibit will review the basic principles and technique behind DECT, and the radiation dose considerations. The exhibit also will review the potential utility of DECT for imaging of the spine. The following applications will be discussed in the exhibit: metal artifact reduction in the setting of penetrating injury or surgical instrumentation, identification and differentiation of crystal diseases such as gout and CPPD, diagnosis of spondylodiskitis, differentiation of acute fractures from old fractures by visualizing marrow edema, improved detection of abnormal epidural enhancement in the setting of infection and postoperative peridural fibrosis, and using DECT myelography to detect spinal cerebrospinal fluid (CSF) leaks. Imaging examples of each of these applications will be demonstrated. In addition, the specific advantages and limitations of these applications of DECT for imaging of the spine will be discussed.
Summary/Conclusion
Recent articles have demonstrated promising results for the application of DECT for imaging of the spine. This exhibit has demonstrated that DECT can be useful to help reduce metal artifact, identify crystal disease, rule out or confirm infection, recognize bone marrow edema, improve detection of epidural enhancement, and optimize detection of spinal CSF leaks.

KEYWORDS: Dual-energy CT, Dual energy spectral

eEdE-167

New Imaging Strategies to Detect Effects of Microgravity on the Intervertebral Disk of Astronauts

Riascos-Castaneda, R. F.[1]·Reza, H.[1]·Cotes, C.[1]·Heymann, J.[1]·Lotz, J.[2]·Hargens, A.[3]
[1]The University of Texas Medical Branch, Galveston, TX,
[2]University of California San Francisco, San Francisco, CA,
[3]University of California San Diego, San Diego, CA.

Purpose
Explain the theories behind the increased low back pain and disk degenerative changes after exposure to microgravity. Show the strategies used to reduce effects of microgravity in space. Explain how new advanced imaging techniques can aid the understanding of the disk degenerative changes and the early detection of them.
Approach/Methods
Educational Exhibit will show: 1. Back pain in space. 2. Effects of spaceflight on the spine. Risk of disk damage in space. 3. Hypothesized spinal unloading in microgravity. 4. Deficiencies of present exercise hardware for space. 5. Pre and postflight tests of crew on international space station. 6. Advanced imaging. 7. Spinal morphology with 3D imaging. 8. Measure water content with T2 mapping. 9. Intervertebral disk spectroscopy. 10. Lumbar spine compressibility tests. 11. In vivo kinematic test.
Summary/Conclusion
Exposure of the intervertebral disk to microgravity has shown to increase the risk of lumbago and disk herniations. We will show the proposed theories to explain these changes based on the microstructure of the

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

intervertebral disk and the strategies that are used to research the causes and early detection of intervertebral disk changes pre and postflight in the astronaut population.

eEdE-168

Diffusion-Weighted Imaging of Usual and Unusual Tumor and Tumor-Like Lesions in the Spine

Smittkamp, C.·Moritani, T.·Kirby, P.·Kademian, J.
University of Iowa
Iowa City, IA.

Purpose
We address the utility of diffusion-weighted imaging (DWI) along with the corresponding apparent diffusion coefficient (ADC) maps in the evaluation of spinal lesions by assessing individual cases across a wide range of pathologies. By assessing common tumors, unusual tumors, and tumor-like lesions, we will show that diffusion-weighted imaging (DWI) can be a helpful tool in lesion detection, lesion assessment, and in distinguishing malignant from benign processes.
Approach/Methods
The DWI and ADC sequences from a total of 270 patient MRIs showing spinal lesions previously diagnosed through a combination of clinical, imaging, and pathologic findings were reviewed. The DWI images were of the spin-echo, echo-planar type with parallel imaging, and the ADC maps were calculated from b values of 0 and 1000 sec/mm2. The lesions evaluated included both primary and secondary malignant tumors as well as benign tumors and tumor-like lesions. They are comprised of lytic and sclerotic bone metastases from a variety of primary lesions (including lung, breast, prostate, glioblastoma, and clear cell meningioma), multiple myelomas, lymphomas, leukemia, osteosarcomas, chordomas, a variety of primary bone tumors (including osteoid osteoma, giant cell tumor, Langerhans histiocytosis), multiple hemangiomas (both atypical and infiltrating type), notochord rests, bone marrow edema with Schmorl's nodes, osteomyelitis with granuloma formations, bone necrosis, and traumatic bone lesions.
Findings/Discussion
Diffusion-weighted imaging often shows hyperintensity with low corresponding ADC values in various malignant bone tumors due to their hypercellularity. Benign conditions do not demonstrate the same hyperintensity. These findings can be useful in detection of a tumor as well as in differentiating malignant and benign conditions (such as typical from atypical/infiltrating hemangiomas). There were, however, some limitations to this result. First, sclerotic bone lesions, even when malignant, did not demonstrate the same DWI hyperintensity, and the ADC values were difficult to evaluate. Additionally, susceptibility artifacts such as nearby surgical devices sometimes inhibited interpretation. Finally, the calculation of ADC values were sometimes hampered due to lesional tissue containing bone or fat.
Summary/Conclusion
We show how DWI and ADC provide utility in the evaluation of the wide variety of spinal lesions. These sequences can aid in the initial detection of lesions; they can help decide the likelihood of a lesion's malignancy by demonstrating hyperintensity due to increased cellularity; and they can be especially helpful in distinguishing between malignant and benign processes that may otherwise appear similar, such as between a hemangioma and atypical/infiltrating hemangioma. We demonstrate these utilities through case examples of a variety of common tumors, unusual tumors, and tumor-like lesions in the spine.

KEYWORDS: Diffusion-weighted imaging, Spinal imaging, spinal lesions

eEdE-169

Brachial Plexus: Review of Anatomy, Imaging Protocol and Spectrum of Abnormalities

Subramanian, S.·Maheshwari, M.·Tolat, P.·Chandra, T.·Midia, E. C.·Kelly, T. G.·Segall, H.
Medical College of Wisconsin Milwaukee
Milwaukee, WI.

Purpose
Brachial plexus pathologies are relatively uncommon and diagnosis can be challenging. MR imaging is the imaging modality of choice for evaluating the brachial plexus for potential pathology. The purpose of this exhibit is to provide a fascile review of brachial plexus MRI anatomy, protocols and pathology.
Approach/Methods
In this educational exhibit, we will review the normal brachial plexus anatomy with MR image correlation, review MRI protocols for evaluation of brachial plexus, and discuss the different brachial plexus pathologies seen in pediatric and adult patients. Brachial plexus pathologies including traumatic, inflammatory, neoplastic processes and mechanical compression will be discussed with illustrative examples.
Findings/Discussion
Injury to brachial plexus may be related to birth trauma in infants or secondary to fall or other traction injuries in older individuals. Imaging findings in these cases could range from nerve root/trunk avulsion, pseudomeningocele, and brachial plexus (or spinal cord) edema/hematoma in the acute phase to denervation changes in the pectoral girdle muscles in subacute to chronic phase. Neoplastic processes affecting the brachial plexus range from primary neurogenic tumors (i.e., schwannoma, plexiform neurofibroma, malignant primary nerve sheath tumors, etc.) or secondary involvement by tumors (i.e., pancoast tumor or leukemic infiltration).

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Brachial plexus compression can be present due to cervical rib or fibrous bands (thoracic outlet syndrome), mass lesion, or fluid collection/hematoma in the axilla. CT angiography also plays a significant role in evaluation of thoracic outlet syndrome.
Summary/Conclusion
Imaging of brachial plexus is unique and technically challenging. MR imaging is the primary diagnostic modality of choice. It is important that the radiologist is aware of the optimal imaging protocol and common abnormalities in order to provide prompt and accurate diagnosis.

KEYWORDS: MR imaging, brachial plexus

eEdE-170

The Postoperative Spine: Hardware, Techniques, and Imaging Appearances

Ratcliffe, M. R.·McCreary, R.·Siripurapu, R.·Herwadkar, A.
Salford Royal Hospital
Salford, UNITED KINGDOM.

Purpose
1. To discuss the imaging techniques and protocols used in the assessment of the postoperative spine. 2. To review the normal imaging appearances of the postoperative status of the spine following various surgical procedures including stabilization, fusion, and disk replacement with various techniques and devices.
Approach/Methods
We present an electronic educational exhibit of the techniques and protocols used to image as well as the normal imaging appearances of the postoperative appearances of the spine.
Findings/Discussion
Spinal surgery is common and has extensively evolved into a complex, specialized field. The goal of this exhibit is to give an overview of common surgical procedures and approaches and discuss the normal postoperative state. Instrumentation is used to provide stability and restore anatomical alignment in the treatment of fractures, degenerative disease, infection, tumors, and congenital deformities. Various posterior and anterior surgical approaches may be used and instrumentation may involve a myriad of devices including screws, spinal wires, vertebral cages, and artificial ligaments and disks. As spinal procedures are becoming increasingly common, the instrumented spine is seen with increasing frequency in routine radiology practice and the radiologist should have an understanding of spinal biomechanics and the common approaches and devices used in spinal instrumentation.
Summary/Conclusion
Evaluating the postoperative spine is challenging due to the continual changes in both surgical technique and hardware. Radiologists, and in particular neuroradiologists, need to be familiar with the normal imaging appearances of the spine following stabilization, fusion, and disk replacement with various techniques and devices.

KEYWORDS: Spinal instumentation, Spinal imaging, postoperative spine

eEdE-171

Imaging of Spinal Cord Syndromes: from Brown-Sequard to Cauda Equina

Baer, A. H.·Parmar, H. A.·Ibrahim, M.
University of Michigan
Ann Arbor, MI.

Purpose
The purpose of this educational exhibit is to review the clinical presentation and neurologic examination of classic spinal cord syndromes and to correlate those with associated imaging characteristics.
Approach/Methods
The following syndromes were compared in terms of their etiologies, presenting neurologic examinations, and characteristic imaging features: Brown-Sequard syndrome, central cord syndrome, dorsal cord syndrome, segmental syndrome, ventral cord syndrome, pure motor syndrome, conus medullaris syndrome, and cauda equina syndrome. Patient cases were collected and graphic illustrations were generated to demonstrate the anatomical distribution of pathology, and a table was created to compare the relative frequency of associated signs and symptoms for each syndrome.
Findings/Discussion
There are eight classic syndromes associated with disorders of the spinal cord and cauda equina. These syndromes are defined by characteristic pain, sensory impairment, motor weakness, abnormal reflexes, altered muscle tone, and related organ (e.g., bowel and bladder) dysfunction. Magnetic resonance imaging in conjunction with clinical information, blood and CSF analysis, and occasionally conventional angiography often can provide a timely and accurate diagnosis.
Summary/Conclusion
Spinal cord syndromes, including acute and chronic processes, are a pathologically heterogeneous group of conditions with potential for permanent neurologic deficit if not diagnosed and managed expeditiously. In many cases, identifying the underlying cause is a diagnostic challenge. Dorsal cord syndrome, for example, has several possible causes (spirochete infection, multiple sclerosis, spinal cord metastases, etc.). Neuroimaging, with close attention to the clinical history and neurologic examination, can reduce the differential diagnosis substantially, often to a single etiology.

Longitudinally Extensive Myelopathy: The Spectrum of Pathology on MR Imaging

Eckart, D.[1]·Poretti, A.[1]·Boltshauser, E.[2]·Huisman, T. A.[1]·Izbudak, I.[1]
[1]Johns Hopkins Hospital, Baltimore, MD, [2]University Children's Hospital of Zurich, Switzerland, Zurich, SWITZERLAND.

Purpose
Abnormal intramedullary spinal cord signal abnormality on magnetic resonance imaging (MRI) in a longitudinally extensive distribution without cord expansion suggests a broad list of differential diagnostic considerations. Making the correct diagnosis requires attention to both the imaging features of the disease, the age of the patient, and the clinical context. This educational exhibit illustrates the spectrum of diagnoses with T2 hyperintense, intramedullary signal abnormality spanning three or more vertebral body segments (longitudinally extensive), including demyelination, cord infarct, metabolic abnormalities, viral and bacterial infection.
Approach/Methods
After obtaining internal review board (IRB) approval, a retrospective review of the clinical database at our institution was interrogated to find cases of longitudinally extensive, intramedullary T2 signal abnormality between 2009 and 2012. Tumor and trauma cases were excluded. Two neuroradiologists reviewed the images and the clinical record, categorizing the etiology as infection, inflammation/demyelination, infarction, edema, metabolic, or vascular abnormality. Images were evaluated for the presence or absence of contrast enhancement, restricted diffusivity if diffusion imaging was performed, presence of blood products, and associated imaging findings such as fracture or ligament injury, flow voids suggesting spinal dural arteriorvenous fistula (dAVF), or postsurgical changes. Additional studies including cerebrospinal fluid (CSF) analysis, spinal angiography, and diffusion tensor imaging were reviewed when available. Cases of demyelinating /inflammatory myelopathy were subcategorized further as neuromyelitis optica, multiple sclerosis, acute disseminated encephalomyelitis, or idiopathic transverse myelitis.
Findings/Discussion
The spectrum of pathology causing longitudinally extensive transverse myelopathy demonstrates considerable overlap. This exhibit explores the varying imaging appearances of both common and rare causes of longitudinally extensive T2 hyperintense signal abnormality as seen in approximately 40 patients with 110 MRI scans. A disproportionate number of our patients had a clinical diagnosis of transverse myelitis, reflecting our institutional bias as a referral center for transverse myelitis with a relatively low trauma volume. Representative images depicting viral and bacterial myelitis, cord abscess, demyelinating diseases (neuromyelitis optica, multiple sclerosis, and idiopathic transverse myelitis), cord infarction, transient cord edema related to hydrocephalus, metabolic derangement, and vascular lesions are presented in an interactive fashion.
Summary/Conclusion
Although many causes of longitudinally extensive spinal cord signal abnormality on MRI have similar imaging appearances, familiarity with the spectrum of clinical and imaging manifestations of these causes helps focus the differential diagnosis. With attention to the patient's age, careful review of the clinical record and CSF analysis, and knowledge of the imaging findings, an accurate diagnosis or limited differential diagnosis can be made prospectively to allow timely management decisions.

Immune Related Disorders of the Spinal Cord: A Pictorial Review

Hoque, K. E.·Lerner, A.·Shiroishi, M.·Torres, F.·Go, J. L.
University of Southern California
Los Angeles, CA.

Purpose
To educate the attendee regarding immune related disorders of the spinal cord.
Approach/Methods
Utilizing the spine teaching files from a major academic institution on the West Coast, the causes of immune related disorders of the spinal cord will be demonstrated.
Findings/Discussion
Immune mediated disorders of the spinal cord are a group of disease processes which are multifactorial in origin. This exhibit will describe the pathophysiology, clinical manifestations, epidemiology, state of the art MR imaging, and briefly describe the treatment strategies for these disease processes. The disease processes to be discussed include multiple sclerosis, Devic's disease, ADEM, immune mediated vasculitis of the spinal cord, Guillain Barre syndrome, chronic inflammatory demyelinating polyneuropathy, and other less common disorders of the spinal cord.
Summary/Conclusion
Immune mediated disorders of the spinal cord are an uncommon but important group of disease processes which may involve the spinal cord. This exhibit serves to educate the attendee regarding this subset of disease entities.

KEYWORDS: Spinal imaging, Spinal cord

eEdE-174

Imaging of Nontraumatic Spinal Cord Abnormalities

Montgomery, J. P.[1]·Haubrich, N.[2]·Blackham, K.[1]
[1]University Hospitals Case Medical Center, Cleveland, OH, [2]Boston College, Chestnut Hill, MA.

Purpose
Myelopathy is a common clinical indication for imaging of the spine with clinical presentations of extremity weakness, parasthesias or bowel and bladder dysfunction. There are many causes of myelopathy including trauma, inflammation, infection, neoplasm and degenerative changes which can become unwieldy to mentally organize and thereby inhibit learning. This exhibit presents a radiologic compartment approach that reduces the intimidation of generating a differential diagnosis.
Approach/Methods
Relevant normal spinal cord anatomy initially is reviewed by way of a labeled comparison of drawings and MR images. Spinal cord pathology then is discussed on the basis of anatomical location: intramedullary, extramedullary-intradural and extradural. These anatomical compartments are further subdivided by etiology including congenital abnormalities, neoplasms, inflammatory processes, infectious processes and vascular abnormalities. These etiologies will be illustrated with exemplar cases.
Findings/Discussion
Spinal cord pathology is complex and intimidating when viewed as a large list of congenital, infectious, inflammatory and degenerative etiologies. Beginning with the spinal cord and moving outward to the meninges and then the vertebral column, common clinical and classic radiologic disorders will be discussed and illustrated with clinical correlation. The discussion also will include the disease demographics and an emphasis on the MRI findings. Entities will include classic congenital malformations such as myelomeningocele, intramedullary pathologies such as astrocytoma, metastasis and demyelination, extramedullary tumors such as meningioma, neurofibroma and dropped metastases, as well as extradural manifestations of cord or nerve root compression such as diskitis-osteomyelitis, disk herniation and bone tumors.
Summary/Conclusion
This exhibit aims to engage the viewer in a focused and easy to understand review of nontraumatic spinal cord pathology utilizing a radiologic compartment approach with an emphasis on MR imaging findings. Topics will be classified by anatomical location and further subdivided by etiology in order to provide an organized approach to spinal cord anomalies that may contribute to the common clinical indication for spine imaging: “myelopathy”.

KEYWORDS: Spinal cord

eEdE-175

Value of MR Imaging and Diffusion Tensor Imaging as Biomarkers for Classifying Acute Spinal Cord Injury

Zoltani, Z.[1]·Zohrabian, V.[1]·Kamali, A.[2]·Gorniak, R. J. T.[1]·Dresner, M. A.[3]·Flanders, A. E.[1]
[1]Thomas Jefferson University Hospital, Philadelphia, PA, [2]Cooper Hospital, Camden, NJ, [3]Philips Medical Systems, Philadelphia, PA.

Purpose
Spinal cord injury (SCI) is a significant problem in the United States with approximately 11,000 new cases per year with an overall prevalence of 250,000 patients living with this condition. Lifetime cost of care averages two million dollars and U.S. expenditures for SCI exceed six billion dollars annually exclusive of lost wages and productivity. Currently there are no “cures” for SCI. The goal of this exhibit is to demonstrate the current role that MR imaging (MRI) plays in the assessment of spinal cord injury and the potential future role diffusion tensor imaging (DTI) could have in improving characterization of injury.
Approach/Methods
While most SCI patients will realize some spontaneous recovery in the first six months after injury, there are only crude metrics available to help discriminate and select for patients that have an intrinsic capacity for recovery versus those that would benefit from some form of novel medical/surgical therapy to promote neural regeneration. Clinical parameters have been used historically to infer the amount of damage sustained to the spinal cord after injury. However, the accuracy of this examination is totally dependent upon the patients ability to cooperate and skill level of the examiner. In the acute trauma setting, the reliability of this clinical exam diminishes and therefore other objective means are needed to directly assess the degree of damage to the spinal cord.
Findings/Discussion
MR imaging has been advocated as the only noninvasive means to directly evaluate the internal architecture of the spinal cord. Three cardinal spinal cord features of SCI on MRI include swelling, edema and hemorrhage. Lesion characteristics, location and length correlate with the neurologic deficit and potentially augment the clinical examination in assessing neurologic recovery. More recently, DTI has been applied to this problem by rendering data related to integrity of white matter tracts. There is both experimental and human data showing that SCI creates a relative decrease in longitudinal diffusivity and increase in radial diffusivity and generalized loss in anisotropy. There are a myriad of technical challenges in measuring these parameters in the human spinal cord using conventional clinical instruments. These include artifacts introduced by motion, the surrounding bony structures, the injury itself as well as limitations of the small target size, spatial resolution/signal and intrinsic time limitations imposed when imaging critical care

patients. The goal of this exhibit is to: (1) introduce the participant to the clinical problems associated with assessing the SCI patient, (2) understand the relationship between assessment and neurologic recovery, (3) review the scientific/clinical evidence on the additional value that MRI provides in directly interrogating the spinal cord architecture, (4) review the principles of DTI and its application to our understanding of SCI and recovery.
Summary/Conclusion
There are both quantitative and qualitative features provided through the combined use of MRI and DTI that can be used as biomarkers in the objective assessment of neurologic impairment in setting of acute SCI. This information could be used to counsel patients/families and as criteria for selective administration of novel therapies.

KEYWORDS: Spinal cord, Diffusion tensor image, neurologic recovery

eEdE-176

Cervical Spine Stability In Trauma: Mechanics, Imaging, and Controversies

Tenenbaum, M.·Alkalay, R.·Hackney, D.
Beth Israel Deaconess Medical Center
Boston, MA.

Purpose
To discuss the mechanics of cervical spine stability after trauma, indications for imaging, and interpretation of CT and MR findings.
Approach/Methods
Stability of the spine depends on integrity of its osseous and ligamentous elements. Spinal ligaments display nonlinear mechanical behavior, a function of their intrinsic tissue structure and visco-elastic nature. They allow mobility while providing increasing kinematic constraints towards the extremes of joint motion. In the upper cervical spine the alar ligament prevents excessive axial rotation at the atlanto-occipital joint, and the transverse ligament limits anterior translation of C1. These provide the primary sources of stability for C1-C2. Primarily due to motor vehicle accidents, alar ligament injury may result in the C0-C2 complex undergoing increased flexion, lateral bending, and axial rotational-based instability beyond the functional range of motion. In the middle to lower spine, the anterior longitudinal ligament (ALL) and posterior longitudinal ligament (PLL), contribute to support and stability of the anterior column. The posterior ligamentous complex (PLC) includes the facet joint capsules, ligamentum flavum and the supraspinous and interspinous ligaments. The PLC contributes to stability by providing resistance to tensile forces in flexion and form the "posterior tension band". High rate injury, resulting in partial or complete tear of the ligaments may result in a highly unstable spine demonstrating significant inter-level translational and rotational displacements, for which the muscular control of the neck cannot compensate in active or passive motion. Injuries to the capsular ligaments result in sagittal, axial, and lateral instability. Classifications have progressed beyond the Denis 3-column concept, and the importance of the posterior ligamentous complex has become increasingly clear. Indications for imaging, particularly for those patients who cannot undergo a full neurologic evaluation, have evolved as imaging technology has advanced. MR reveals apparently significant injuries in some patients with no evidence of fracture. The correlation of MR-apparent ligamentous injury with surgical findings is far less than perfect. The prevalence of destabilizing ligament injury in patients with normal CT scans is uncertain, with widely divergent values reported in the literature. Some studies have found near perfect sensitivity and negative predictive value of CT for detecting clinically significant post-traumatic spinal instability. The severity of ligamentous injury ranges from laxity to frank disruption, and there are as yet no proven criteria for MRI findings corresponding to functional insufficiency in the absence of frank tears. Consequently, the role of MR in acute evaluation also is controversial. Keeping ICU patients in collars for prolonged periods of time while awaiting imaging results or neurologic recovery can lead to complications, particularly for those with head injuries. This "conservative" approach may have significant detrimental effects.
Findings/Discussion
We will review the mechanical principles of spine trauma, indications for CT and MR imaging, and interpretation of these studies in terms of spinal stability.
Summary/Conclusion
The evaluation of cervical spine trauma is an essential topic in radiology practice. Introduction of progressively advanced imaging had lead to controversies over the role of imaging in management, which studies should be obtained, and how they should be interpreted.

eEdE-177

Imaging of the Thoracolumbar Spine Injuries in Trauma with the Introduction of New Concepts

Khorrami-Arani, N.[1]·Liang, T.[2]·Ouellette, H.[1]·Munk, P.[1]·Nicolaou, S.[1]
[1]Vancouver General Hospital, Vancouver, BC, CANADA,
[2]University of British Columbia, Vancouver, BC, CANADA.

Purpose
Each year, over 30,000 injuries to the spinal column occur from trauma, of which the majority are due to blunt trauma. These injuries often can result in neurologic damage; thus, it is important to recognize these injuries early to allow prompt diagnosis and management. The purpose of this exhibit is to review the imaging modalities and findings available for acute thoracolumbar spine injuries, defined as injuries involving the thoracic (T1-T12) and lumbar (L1-L5) spinal segments, and review and

Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

discuss the utility of a new classification scheme for the thoracolumbar spine for prognosis assessment and clinical management.
Approach/Methods
A retrospective review of cases of thoracolumbar spine injury from our institution will be conducted.
Findings/Discussion
This educational exhibit will review the pathophysiology and clinical presentation of acute thoracolumbar spine injuries, and discuss indications for acute thoracolumbar spine imaging. We will discuss the findings, strengths and weaknesses, and demonstrate examples of lateral radiographs, CT, and MR imaging (MRI) as imaging modalities for thoracolumbar injuries. A review of the classification systems available for imaging of thoracolumbar spine fractures will be conducted, with emphasis on the new thoraco-lumbar injury and classification scale (TLICS). The three main independent characteristics for assessing a thoracolumbar injury include morphology, integrity of posterior ligamentous complex and the neurologic status of the patient. The usefulness of each factor will be reviewed, and imaging examples of the application of the classification scale will be demonstrated. Finally, the efficacy and ability of TLICS to help guide the team towards either a surgical versus nonoperative management will be evaluated.
Summary/Conclusion
The TLICS system is a new and well accepted classification system for the diverse presentation of thoracolumbar injuries. It is based on three major components for assessment: the morphology of the injury, the integrity of the posterior ligamentous complex, and the neurologic status of the patient. An overall severity score is used in conjunction with the classification system, and allows determination of prognosis and helps guide management. After reviewing this exhibit, the reader will understand the TLICS classification and be able to quickly and accurately diagnose thoracolumbar injuries, and efficiently aid the trauma team in clinical management decisions.

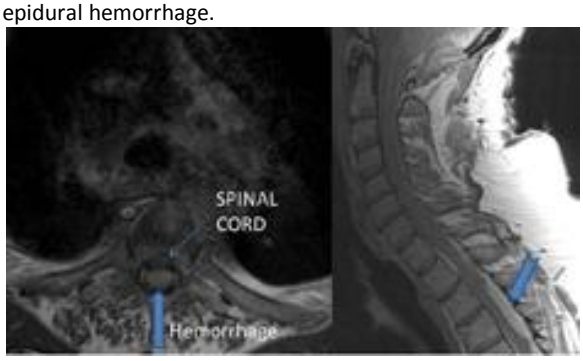
KEYWORDS: Spinal trauma, thoracolumbar spine injury

eEdE-178

Localization of Spinal Subdural Hemorrhage: How Confident Are We?

Gandhe, A. R.·Flanders, A.·Patel, F.·Mohiuddin, J.·Chopade, T.·Patel, R.·Sharma, D. K.
Thomas Jefferson University Hospital
Philadelphia, PA.

Purpose
MR imaging (MRI) is considered to be investigation of choice for spinal hemorrhage. Even though MRI is able to evaluate the location, extent and compressive effects of hemorrhage, diagnosing the exact space of hemorrhage may be difficult. The purpose of the exhibit is to discuss those spinal hemorrhages which by imaging criteria appear to be in one space (i.e., epidural/subdural/subarachnoid) and found to be in another space intraoperatively.
Approach/Methods
Patients operated for spinal hemorrhage were evaluated retrospectively for location of hemorrhage. MR imaging was specific in location, extent, compressive effects, spinal cord changes, and to exclude associated lesion. There were few cases where spatial localization of hemorrhage on MRI did not match with intraoperative findings.
Findings/Discussion
Case 1. A 72-year-old male presented with intracranial and spinal hemorrhage after fall. He had history of DVT and was on heparin. MR imaging spine demonstrated extensive subdural hemorrhage dorsally from T1-T2 to L3-L4; causing anterior displacement of spinal cord. Intraoperative findings demonstrated subarachnoid hemorrhage. Case 2. A 75-year-old male presented with lower extremity pain after epidural injection. MR imaging lumbar spine demonstrated small epidural hemorrhage centered at L4-L5 with large associated subdural hemorrhage. Epidural fat was largely preserved, anterior margin was irregular and dura was not visualized. Postoperative findings demonstrated only epidural hematoma. Case 3. A 49-year-old patient presented with progressively increasing lower extremity weakness and numbness. He was on coumadin. MR imaging lumbar spine demonstrated crescent-shape dorsal extra-axial hemorrhage with largely preservation of epidural fat. Dura was not visualized. Postoperative findings demonstrated epidural hemorrhage.



Note: Scanned images are included in the proceedings. Some submitted images were reduced during editing, thereby decreasing clarity. Also, refer to the Program Planner. Proceedings Content as of 3-29-2013.

Imaging Findings of Spinal Hemorrhage	
Spinal Epidural Hemorrhage (SEH)	Spinal Subdural Hemorrhage (SSH)
Involvement of epidural fat	Epidural fat preserved
Presence of curtain sign	Absence of curtain sign
Visualization of dura matter	Nonvisualization of dura matter
Lentiform shape	Crescent shape
Regular anterior margin	Irregular anterior margin
Tapering craniocaudal margins	Nontapering craniocaudal margins
Smaller craniocaudal extent	Long craniocaudal extent

Summary/Conclusion
Localization of space of hemorrhage has significant role in management of spinal hemorrhages. MR imaging is investigation of choice in evaluation of spinal hemorrhage; however, occasionally, exact localization of space of spinal hemorrhage especially subdural hemorrhage is not possible. One should always think possibility of spinal epidural and rarely subarachnoid hemorrhage, though imaging findings favor subdural hemorrhage.

KEYWORDS: Spinal trauma, Hemorrhage, subdural

eEdE-179

Imaging of Cervical Spine Injuries

Khorrami-Arani, N.[1]·Liang, T.[2]·Shewchuk, J.[1]·Nicolaou, S.[1]
[1]Vancouver General Hospital, Vancouver, BC, CANADA,
[2]University of British Columbia, Vancouver, BC, CANADA.

Purpose
Age-adjusted incidence rates in Canada for spinal cord have been estimated to be 50.87 per million per year. Of these injuries, the majority are caused by blunt trauma. Two to three percent of blunt trauma victims suffer cervical spine (C-spine) injuries, and 40-50% of these injuries result in neurologic damage. It is important to recognize these injuries early for prompt diagnosis and management. The purpose of this exhibit is to review the imaging modalities and findings for acute C-Spine injuries, review indications for imaging, and discuss the utility of a classification and scoring system for the cervical spine.
Approach/Methods
A retrospective review of cases of C-spine injury from our institution will be conducted.
Findings/Discussion
This educational exhibit will review the pathophysiology and clinical presentation of acute C-spine injuries, and discuss indications for acute C-spine imaging with review of the Canadian C-spine rule, NEXUS study criteria, and CCR study criteria. We also will review the subaxial injury classification (SLIC) and severity score for acute C-spine fractures. The utility of MDCT in assessing the C-spine in an obtunded patient will be demonstrated with imaging examples. We will discuss and demonstrate the findings of acute C-spine injuries on radiography, CT, and MRI, and review the strengths and weaknesses of each imaging modality.
Summary/Conclusion
There are limitations in detecting upper and lower C-spine skeletal injuries on radiographs. CT is the most useful and informative imaging tool for C-spine skeletal trauma, and MRI is the imaging modality of choice in investigating ligamentous and spinal cord injury. Criteria exist to indicate which patients need imaging to evaluate for possible acute C-spine injury, and we have reviewed a system for scoring injury severity.
